Food, Drug and Cosmetic Act: Right of Government to Seize Misbranded Device in Possession of Purchaser.—This was an action on behalf of the government to seize and possess a device found in the possession of the defendant, a private citizen, who had purchased it. From a judgment in favor of the defendant in the trial court, the government appealed to the U. S. circuit court of appeals, ninth circuit.

The federal Food, Drug and Cosmetic Act provides that "Any article of food, drug, device, or cosmetic that is adulterated or misbranded when introduced into or while in interstate commerce . . . shall be liable to be proceeded against while in interstate commerce, or at any time thereafter, on libel of information and condemned . . ." and provides further that "A drug or device shall be deemed to be misbranded . . . if its labeling is false or misleading in any particular." It was undisputed, said the court of appeals, that the article in question

—a so-called Spectro-Chrome—was an instrument, apparatus, or contrivance intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease of man and hence was a device, within the meaning of the food and drug act. The article was transported in interstate commerce in June 1945. When the article was introduced into and while it was in interstate commerce, its labeling was false and misleading. Hence the article was misbranded, within the meaning of the act, when introduced into and while in interstate commerce. This proceeding was commenced in July 1945 after the article had been purchased by the defendant and was therefore no longer in interstate commerce. That fact, said the court of appeals, is immaterial. Having been misbranded when introduced into and while in interstate commerce, the article was liable to be proceeded against and condemned at any time thereafter.

It is immaterial, continued the court, that the defendant purchased and paid for the article, had it in his home, was satisfied with it and desired to keep it. It is likewise immaterial that the article was not inherently dangerous or harmful, that the defendant did not intend to use it commercially or to permit its use by persons other than himself and his mother and brothers, all of whom were over 21 years of age, and that defendant believed that he and his mother had been benefited by its use. Such facts could not and did not exempt the article from the provisions of the federal act. It was contended that the defendant had a right to prescribe for himself and to "seek to cure himself of physical ailments by any means he chooses, so long as the means chosen is not inherently dangerous or harmful." Such a right, said the court, if it exists, is subordinate to the rights of the government under the act.

The judgment of the trial court in favor of the defendant was therefore reversed.—*United States v. Olsen*, 161 F. (2d) 669 (1947).

Hospitals: Accrual of Action for Wrongful Death Due to Negligence.—This was an action for damages for the wrongful death of the plaintiff's husband caused by the alleged negligence of the defendant hospital. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Florida.

The deceased was injured on Aug. 27, 1942, entered the hospital the next day and was discharged September 10. He returned to the hospital on Sept. 15, 1942 and died the following day of tetanus resulting from the injury. The negligence alleged to have resulted in death is that reasonable and proper care of the deceased required that he be given tetanus antitoxin but that the defendant failed to give this treatment. The Florida statutes require that "an action arising upon account of an act causing a wrongful death" shall be commenced within two years, and this action was commenced Sept. 12, 1944, within two years of the death but not within two years of the alleged negligent conduct. The question, therefore, said the court, is, does the statute of limitations in a death case commence to run from the date of the wrongful act or from the date of death?

The Supreme Court cited a statement from American Jurisprudence (16 Am. Jur., Sec. 167) saying that the point of time which marks the commencement of the running of a statute limiting the right of action for death by wrongful act is a matter that must be determined generally from the provisions of the statute creating the limitation, but that the general rule is that the cause of action accrues and the statute runs from the time of the death. The plaintiff's cause of action, continued the court, is dependent on death, and it is our conclusion that it was the intent of the Florida statute to limit the commencement of the action from the time of the accrual of plaintiff's cause. Plaintiff's cause of action did not accrue by reason of the wrongful act alone; it took a wrongful act plus death to give the plaintiff a cause of action. The statute of limitations therefore commenced to run at the time of death. Accordingly the judgment in favor of the plaintiff was affirmed.—*St. Francis Hospital, Inc. v. Thompson*, 31 So. (2d) 710 (Fla., 1947).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Vaginal Smears and Tissue Diagnosis.—Isbell and his associates report on 1,045 vaginal smears and the corresponding uterine, cervical and/or vaginal tissue sections. In 1,000 of these cases 60 cancers of the uterus, cervix or vagina were encountered. In 40 cases of carcinoma of the cervix, 39 smears were positive and 1 was not. In 18 cancers of the uterus, 15 smears were positive and 3 were negative. Two carcinomas of the vagina were encountered, and in both the smears were positive. The total error of positive cases called negative was 6.66 per cent. In the remaining 940 cases with negative tissue sections there were 11 false positive vaginal smears, giving an error of 1.7 per cent. Analysis of 41 cases of definite or questionable carcinoma in situ, in which the tissue diagnosis might be considered equivocal, revealed 8 positive and 5 negative smears in 13 carcinomas of the cervix. Only 1 positive smear was found in 7 carcinomas of the endometrium. Four positive smears were encountered in 13 questionable carcinomas of the cervix. No positive smear was found in 8 questionable carcinomas of the endometrium. With regard to this last group, the authors say that the difficulty of an accurate smear diagnosis is understandable in view of the fact that this lesion is deeply situated and is thus less apt to cast off cells directly into the uterine cavity. Four incidental cancers were encountered, including one each from the bladder, urethra, vulva and fallopian tube. Positive smears in all 4 instances indicate that malignant cells from such sources may be carried into the vagina. The vaginal smear method is an accurate and valuable adjunct to a gynecologic clinic.

Two Hour Rat Test for Pregnancy.—Two cubic centimeters of an unaltered morning specimen of urine was injected intraperitoneally in divided doses of 1 cc. each into the right and left lower abdominal quadrants of an albino rat. Two hours later the animal was killed by ether asphyxiation. The test was considered negative if the ovaries were pale or pinkish and positive if one or both of the ovaries were light to dark crimson. Fried stresses the rapidity of the test, the high sensitivity as indicated by the accuracy in cases of disturbed pregnancy, the rarity of false positive tests and the great tolerance of the rat to the toxic specimens of urine. Improvements in the test are desirable, because its accuracy ranged below that of the Friedman test in normal intrauterine pregnancy. It is advisable to obviate the large number of false negative and doubtful reactions, which caused a feeling of uncertainty in reporting negative tests, and to increase the color intensity of positive reactions and lessen the need for three rats per test.

Penicillin in Interstitial Keratitis.—Klauder treated 72 patients, 22 men and 50 women between the ages of 5½ and 46 years, who had interstitial keratitis with penicillin. Sufficient time has elapsed to evaluate the results of treatment in 59 of these patients. Forty-one of the 59 patients were given intramuscular injections of 50,000 units of commercial sodium penicillin every four hours for forty-eight consecutive doses in eight days, to a total amount of 2,400,000 units. In the remaining 18 patients the total dosage of penicillin ranged from about 0.5 million units (2 patients) to about 4 million units. The majority received about 2,000,000 units in eight days. Penicillin was well tolerated without serious untoward reactions. The Herxheimer reaction was absent after initial treatment. Twenty-five patients were given penicillin alone. Penicillin combined with eight to twelve fever rises from vaccines were given to 9 patients; penicillin, fever and chemotherapy to 21 patients, and penicillin and chemotherapy to 4 patients. Among the 25 patients treated with penicillin only, interstitial keratitis progressed favorably or was retrogressing at the time penicillin was given so that supplemental treatment was not regarded as necessary. Penicillin, like chemotherapy, did not prevent an initial attack of interstitial keratitis, or involvement of the second eye or recurrence of the disease in the previously affected eye. The absence of any striking result in the final visual acuity of the penicillin-treated patients is consistent with clinical observation that penicillin does not uniformly exert an immediate favorable effect on active interstitial keratitis. The considerable individual variation in the course of this disease is apparently not altered by penicillin therapy. Interstitial keratitis which is retrogressing at time of treatment pursues a favorable course, as do mild cases of the disease. An occasional severe case seems to be benefited. Other severe cases of the disease were definitely not improved by penicillin or any other method of treatment. Retreatment with penicillin in refractory cases does not seem to be of benefit. There was no apparent effect after the local use of penicillin. The addition of penicillin to the therapy of interstitial keratitis does not give results superior to those of other forms of treatment.

Penicillin in Neurosyphilis.—Curtis and his co-workers treated 118 patients, 77 men and 41 women, whose average age was 40.4 years and who had some type of syphilis of the central nervous system: 75 were treated with penicillin, the remaining 43 with penicillin and malaria therapy. With few exceptions penicillin was administered in equally divided doses of 40,000 units each and was given intramuscularly in aqueous solution every three hours for one hundred injections. All patients were followed for a minimum of one year. In both the clinical results and the spinal fluid picture the patients responded more satisfactorily to the combined method of treatment than to penicillin alone. Fifty-eight of the patients had either paresis or taboparesis. The more severely affected patients (30) received combined treatment and the remaining 28 were given penicillin alone. From observations made one year following treatment the impression was that penicillin combined with malaria is the treatment of choice in these types of neurosyphilis. Patients with tabes dorsalis responded equally well to penicillin or to malaria and penicillin, as revealed by observations for one year after treatment. This was supported both by clinical and spinal fluid examinations. Five patients with inactive spinal fluids failed to revert to negativity one year after treatment. Nine patients with primary optic atrophy due to syphilis were treated. Arrest of the degenerative process seemed apparent one year after treatment in 4 patients who had received penicillin alone and in 4 who were given penicillin plus malaria therapy. Progression of the optic atrophy was evident in 1 patient receiving the combined treatment. One year of observation is too short a period to serve as the basis for any definite conclusions.

Calciferol and Dihydratichysterol in Sarcoidosis.—Curtis and his associates report 5 cases of sarcoidosis. One patient with multiple superficial sarcoid lesions of the skin, another with deep sarcoidosis involving skin, eyes and central nervous system, and a third with deep lesions of the skin of the forehead obtained resolution of their lesions following treatment with calciferol (vitamin D₂). A patient with sarcoid both of the skin glands and lungs was greatly improved by calciferol therapy. A patient with extensive sarcoidosis of skin, lungs and bones was greatly improved by the administration of dihydratichysterol. This agent apparently causes less calcium

absorption and more phosphorus excretion than does calciferol. If the beneficial effects of calciferol are due to its effect on phosphorus elimination, then dihydratichysterol should be at least equally as effective, if not more so. One patient was placed on a regimen using dihydratichysterol. Improvement was noted in the skin and lungs, with some regeneration of bone in the phalanges of the great toes. The authors suggest that the beneficial effect of both calciferol and dihydratichysterol is due to the tendency of such treatment to increase phosphorus excretion, thereby decreasing in the phospholipids of the tissues the phosphorus content, which may be the causative factor in the production of the epithelioid tubercles of sarcoid. Toxic reactions were present in all patients, but permanent damage was not produced.

Coccidioidomycosis in New England.—Coccidioidomycosis is seldom found along the Atlantic Seaboard. Kurz and Loud stress that owing to the tremendous displacement of persons from their native areas during the war, clinicians must be aware that the disease may appear in New England, particularly in persons who have seen service in areas where coccidioidomycosis is endemic. They review observations on 4 servicemen who returned to their native environment with coccidioidomycotic infections. The first patient sought treatment because of a severe ulcerative granulomatous lesion of nose and lips. Biopsy revealed fungi, and roentgenograms of the lung revealed conditions more consistent with coccidioidomycosis than with tuberculosis. A skin test for Coccidioides immitis was positive. This case yielded to roentgen therapy after having failed to respond to sulfonamide drugs, penicillin, streptomycin and iodides. The authors stress the necessity of frequent roentgen examinations of persons who have been in areas endemic for coccidioidomycosis; in such persons cutaneous lesions, particularly those of a granulomatous nature, should be studied for the presence of the fungi. If coccidioidomycosis is kept in mind and histories of the possibility of exposure are taken, there should be no difficulty in separating these cases from tuberculous infections. The ring shadows are fairly

sharply defined, and there is no reaction around them. Metastatic cancer and bronchiogenic carcinoma may also be simulated, but the multiple lesions in the former and the absence of atelectatic areas in coccidioidomycosis should serve as differential features. Positive skin tests and serologic tests help to confirm the roentgenologic findings.

Rutin for Capillary Abnormality in Hypertension.—In a study of 265 hypertensive subjects, Griffith and Lindauer noted an increased incidence of apoplexy and retinal hemorrhage in those with increased capillary fragility. In 1,200 hypertensive subjects subsequently reported, it was found that 20 per cent manifested increased capillary fragility, while an additional 10 per cent had increased capillary permeability with normal fragility. A history of apoplexy and retinal hemorrhage was obtained in 9 per cent, each, of the group with increased capillary fragility and permeability, and in 2 per cent of the remainder. During the follow-up period, rutin was given and tests for capillary fragility became normal in 75 per cent of the patients whose tests had been initially abnormal. The initial dosage of rutin is 20 mg. by mouth three times a day. Tests for capillary fragility are repeated at regular intervals, and the dosage is increased whenever the results are abnormal. Capillary fragility and permeability, if originally increased, usually become normal after adequate dosage of rutin continued for a long enough time. It is probable that such change in the outcome of the test indicates a lessened likelihood of the development of apoplexy and retinal hemorrhage.

Anticoagulant Therapy in Mesenteric Thrombosis.—Engelman reports the history of a man aged 73, in whom a tentative diagnosis was made of mesenteric thrombosis or acute appendicitis. Exploratory laparotomy revealed a thrombus in the mesentery at the junction of the ileum and cecum. Because of the advanced age of the patient, an appendectomy and resection were not considered. It was considered that anticoagulant therapy might prevent further thrombosis and that recovery might ensue if the ileum was at all viable. Decompression was instituted by Wagensteen suction, and "dicumarol" 150 mg. was inserted in the tube. Concomitantly 100 mg. of heparin was given intravenously. The Wagensteen tube was replaced by a Miller-Abbott tube. All "dicumarol" was administered by the tube, and suction was shut off for three hours following administration. The patient recovered. The author believes that anticoagulant therapy played a major role in the recovery.

*Rural Accidents. R. L. MacCormack.—p. 1118.

Rural Accidents.—MacCormack analyzes 333 accidents that occurred in a rural community in the course of a year. Nearly three fourths of the accidents occurred in the afternoon. The highway accidents occurred chiefly at night. The author believes that physical and mental fatigue toward the end of the day and haste to get through with the day's work account in large measure for afternoon accidents. Farming is one of the most hazardous of occupations. Many times a farm worker comes close to being hurt. Only experience in timing his movements keeps him from injury. A lack of alertness from fatigue, undue haste or carelessness may bring disaster in the operation of varied farm implements. While a worker in industry may have to protect himself in operating only one stationary machine, a farmer operates a dozen or more different machines in various states of repair and propelled by either animal or motor power over smooth or rough terrain. The author stresses the need for a publicity campaign to reduce accidents. Analysis of the accidents suggested that 34 per cent were obviously preventable, or 23 per cent reasonably preventable and 43 per cent probably not preventable.

*Calciferol Treatment of Lupus Vulgaris. D. J. Macrae.—p. 333.

Absorptive Property of Various Ointments. J. Rae.—p. 338.

"Teverfew Dermatitis." A. K. Daniels.—p. 340.

Calciferol for Lupus Vulgaris.—The report by Macrae is based on 20 cases of lupus vulgaris, in which patients were sent for institutional treatment when other forms of treatment had failed. The average age of the patients was 38, and the average number of years they had had the disease was nineteen. The dose used was 150,000 units of calciferol per day by mouth or 600,000 units twice a week by injection. After the first two or three weeks of treatment the lupus patches looked more "angry" and swollen. After three weeks, improvement commenced but some of the worst cases did not show much change for five to six weeks, after which progress has been seen in every patient. When improvement began the lupus became flatter, and many of the patients mentioned how much softer the lesion felt. It has been possible to discharge 5 patients, 3 without evidence of lupus but 2 with a few nodules. All patients have shown some improvement. Disadvantages include the risk of toxic effects, hypervitaminosis and renal calculi. The author was struck with the amount of pigment occurring in many of the patients, which makes many of them still look unsightly. He now combines calciferol with local treatment using a combination of Kromayer and brass paste. So far, when that has been used, the soreness and breaking down of the lupus has not been nearly as marked, and the resultant ulcers healed more quickly.

British Journal of Ophthalmology, London

31:581-648 (Oct.) 1947

*Treatment of Traumatic Diplopia. J. C. Neely.—p. 581.

Treatment of Traumatic Diplopia.—During the war, the incidence of diplopia following injuries of the head and face has risen steeply, and a technic for the treatment of these cases has now been worked out. Between 1942 and 1944 more than 200 cases of diplopia due to injury were seen at routine examinations in two service hospitals. Diplopia is caused usually by a paresis and not a paralysis of an extraocular muscle. In the majority of cases, the closed head injury and not the penetrating head wound is the cause of diplopia. The vertically acting muscles are most often affected. In fractures involving the orbit, the orbital floor can be built up by means of a bone inlay if immediate restoration has not been effected. Well planned surgery of the eye muscle, aided by orthoptic exercises, is the best means of overcoming the residual diplopia and of restoring binocular single vision.

Scrotal Pneumocoele as Transient Complication of Artificial Pneumoperitoneum. W. N. Rogers and J. V. Garrett.—p. 70.

Thoracic Neurofibroma.—D'Abreu observed 8 neurofibromatous tumors in the course of a year and has removed 7. All were causing symptoms such as pain, tracheal compression, "asthma" and "pneumonia." The differential diagnosis from cysts, dermoids, chondroma, retrosternal goiter and such rare conditions as lipoma was usually not difficult, and the fact that all were causing symptoms made the decision to operate an easy one. The operative removal was easy because of the simple nature of the tumors and because all had a large solitary pedicle. This is not always the case in these tumors, the removal of

which may be highly difficult if malignant transformation has taken place. One tumor was not operated on because a metastasis to the neck was subjected to biopsy and seen to be cancerous. The author believes that many of these tumors are being discovered by mass radiography. He considers it highly advisable to operate on these, even if they are symptomless. The danger of their removal should be slight if malignant change has not occurred. It seems unwise to allow a high rate of transformation to cancer to develop.

*Gaucher's Disease Without Splenomegaly. Margaret E. Morgans.—p. 576.

Dropsic Cot in Hospital. W. Napier.—p. 578.

Cystic Disease of Breast.—Pullinger believes that human and experimental cystic disease of the breast are comparable. Discrepancies exist in the interpretation of the manner in which the cysts develop. Both conditions are probably brought about by excess of estrogen acting on mammary epithelium that responds atypically. The decisive factor is not merely excess or imbalance of estrogen but the nature of the parenchyma. Cystic disease of the breast is an entity independent of mammary cancer. It does not predispose to mammary cancer of mice when the cancer is activated by the tumor agent.

Sodium Antimonyl Tartrate in Kala-Azar.—Adams and Seaton report on intensive administration of sodium antimonyl tartrate in Indian kala-azar. The preparation used was a sterile 2 per cent solution of sodium antimonyl tartrate. The total dosage for each patient was about 1 Gm. per 12 pounds (5.4 Kg.) of body weight in six intravenous injections given at intervals of three hours, usually at 9 a. m., noon and 3 p. m., on two successive days. The appropriate dose was made up to 15 or 20 cc. with isotonic sodium chloride solution and injected intravenously. Of the 6 patients treated, 1 did not respond and another required a second course of treatment. The other 4 were probably cured, but the possibility of a subsequent relapse cannot be entirely excluded. The results of intensive antimony treatment in these few cases do not compare favorably with those obtained with ethylstibamine ("neostibosan") or with "urea stibamine," a full course of either of which produces a cure rate of 90 to 95 per cent, or with the aromatic diamidines. The method can at present be recommended only when many patients have to be treated rapidly and the cost of treatment is an important consideration.

Gaucher's Disease Without Splenomegaly.—Morgans presents the histories of a father, his two sons and a daughter, all of whom had Gaucher's disease. The diagnosis was made by the detection of Gaucher cells in the bone marrow and by the presence of typical radiologic lesions in the bones. The family history suggests that in this series the disease was not only congenital and familial but also hereditary. All had led, or were leading, active lives, and in 1 case the diagnosis was first made at the age of 67 years. The unusual aspect of these cases of Gaucher's disease was that splenomegaly was absent.

Follow-Up of Poliomyelitis Patients.—Arvola made follow-up studies on 117 patients who had had the paretic form of poliomyelitis between 1937 and 1942. He observed that at present the disease is as frequent in adults as it is in children and that children seem to have milder forms of the disease. The mortality in adults reached 32 per cent, while in children under 7 years of age it was zero. The mortality among males exceeded considerably that among females. There was a complete recovery in a sixth of the 90 patients with paretic poliomyelitis; in three fifths of the patients invalidism amounted to less than thirty per cent. Eighty-seven per cent of the patients over 18 years of age were self supporting. The tendency of the muscular pareses to recover was found to be the greater, the milder the pareses had originally been. Complete paralyses and the severest pareses improved little or not at all. In patients under 15 the degree of shortening of the paretic extremity was found to be related to the severity of the paresis at the beginning. In children serious pareses of extremities always resulted in a relative shortening of the limb, but mild pareses never involved shortening. Joint contracture and flaccid joints were the most frequent deformities in children, scoliosis of the spine in adults.

Desoxycorticosterone in Infantile Atrophy.—According to Forsell infantile atrophy (athrepsia or marasmus) is characterized by a gradual disturbance in the inner nutritional functions, leading to losses of the liquid and solid body substance. The entire subcutaneous fat tissue may disappear. In addition to disturbances of the water-binding and salt-binding functions, a protein-electrolyte disturbance of the blood has been found in marasmus. Some consider that an insufficiency of the suprarenal glands, occurring in connection with alimentary intoxication, combustion toxicosis and certain infectious diseases, contribute to the clinical picture of this pathologic state. The fact that Hislop and von Szász obtained favorable results from suprarenal cortex therapy and that infantile atrophy is a shock-like condition induced the author to try desoxycorticosterone in 4 cases of grave infantile atrophy. The treatment proved effective. Although this number of cases is too small to justify general conclusions, the author believes that it would be well to try cortical hormone in infantile atrophy. Desoxycorticosterone seems to reestablish the fluid-binding functions and to increase tolerance to food in the form of breast milk and calory-rich mixtures and thus to bring about a normal increase in the infant's growth.

- *Acute Leukosis in Children. E. G. Caselli.—p. 12.

18:73-144 (Aug.) 1947. Partial Index

- *Acute Leukosis in Children: Conclusion. E. G. Caselli.—p. 103.

Leukosis in Children.—Caselli observed 16 cases of acute leukosis in children during the period from 1935 to 1946. The majority of the patients were between the ages of 9 months and 6 years. The clinical symptoms were those of an acute infection, progressive anemia, hemorrhagic syndromes and painless enlargement of the liver, spleen and lymph nodes. Hematologic observation showed progressive, acute anemia with a scanty number of erythroblasts, changes in the number and form of leukocytes, granulocytopenia and in some cases lowered platelet determinations. Bone marrow studies in 8 cases showed granulocytopenia, in 7 lymphopenia and in 1 erythroblastosis.

Treatment consisted of repeated blood transfusions, proper diet and administration of vitamins B and C, iron, liver and alkaline preparations. The course in the fatal cases varied between sixteen days and two months.

Chirurg, Würzburg**17/18:97-144 (Dec.) 1946. Partial Index**

- *Trophic Nerves and Dupuytren's Contracture. P. Reichel.—p. 97.
*Duodenal and Ventricular Ulcer Due to Disturbance in Blood Perfusion. V. Hoffmann.—p. 100.
Successful Treatment of Osteodystrophia Fibrosa Generalisata (Engel-von Recklinghausen) by Removal of Parathyroid Tumor. Annelies Jentsch.—p. 103.

Trophic Nerves and Dupuytren's Contracture.—Reichel includes in the concept of trophic nerves not only the vasomotor nerves but all nerve fibers which, directly and without interference of circulation, control, the chemical processes that take place in the cells. He cites keratitis of the homolateral eye that often develops following excision of the gasserian ganglion as a typical example. That it is the sequel of the division not merely of the vasomotor nerves but of really trophic nerves is made highly probable by the fact that in some cases the primary involvement of the homolateral eye is followed secondarily by development of the same disorder in the other eye by way of Hagedorn's "trophic reflex." The author regards Dupuytren's contracture as a typical example of involvement of purely trophic nonvasomotor nerves. He denies that it is the result of cicatricial shrinkage and questions the supposition that it results from continued pressure on the hand in the course of hard physical labor, pointing out that bilateral occurrence seems to contradict this. A hereditary factor seems to play a part in some instances. In 1916 he called attention to the occurrence of Dupuytren's contracture following functional impairment in the region of the ulnar nerve. In a single year he encountered 4 cases of this type; in 3 cases the nerve had been injured, while the fourth case concerned a patient with tabes, in whom the ulnar region of the spinal cord was involved. Reichel cites the case of a man who had sustained a grenade injury at the inside of the right elbow with subsequent paralysis of the right ulnar nerve. The right hand showed claw formation, whereas the left hand showed Dupuytren's contracture. The author regards this concurrence of traumatic ulnar paralysis on the right side with the subsequent development of Dupuytren's contracture on the left side not as accidental but rather as exemplifying a trophic reflex. Causalgia after injury to nerves differs in certain respects from Dupuytren's contracture by the presence of vasomotor factors. Although there is no definite anatomic proof of the existence of purely trophic nerve fibers, it appears that Dupuytren's contracture is at least a trophoneurosis and presumably the result of involvement of the purely trophic fibers.

Impaired Blood Perfusion in Duodenal and Ventricular Ulcers.—Hoffmann reports microscopic studies on slight changes found in typical ulcer locations in the duodenal bulb. He found in resected specimens small areas of unevenness and retractions at the site opposite to a deep callous ulcer, that is, at the site of the "kissing ulcer." Surface defects were absent in these areas of retraction, but microscopic sections disclosed a degenerative process in the depth of the duodenal wall; the mucosa was generally intact or involved only in its lowest layers of Brunner's glands and the lymphatics. The surface layer of the mucosa was not perforated. The muscle layers were entirely or almost entirely destroyed. The lesion does not enter the tissue from the lumen and the mucosa but rather from the inner layers. The blood vessels are the starting point of this lesion, which is essentially an infarct in which the extent of vascular blockage determines the degree of tissue destruction. The process is an ulceration without an open ulcer, the latter being a complication. The acid or mechanical theories cannot explain this process. At any rate there are typical duodenal ulcers which develop from the inner layers of the duodenal wall into the mucosal layer, as an infarct. This deep ulcer can be interpreted as the result of a disturbance in the blood perfusion. Peptic digestion does not as yet play a part.

Book Notices

Practical X-Ray Treatment. By Arthur W. Erskine, M.D. Third edition. Fabrikoid. Price, \$1.50. Pp. 155, with 22 illustrations. The Bruce Publishing Co., 2612 University Ave., Saint Paul 4, 1947.

The pleasure of reading a book such as has been prepared by Dr. Arthur W. Erskine has been renewed with each of the three editions; the book may be regarded as essential for the library of every radiologist.

Eight chapters concern apparatus, measuring instruments, factors affecting skin dosage, factors affecting the depth-dose percentage, standard techniques, scattering and distribution, determination of the skin dose, effects of roentgen rays on tissue. Five chapters are on methods of treatment of malignant and noncancerous conditions.

From the wealth of the author's experience he has provided for a therapeutic radiologist an excellent discussion of the various factors concerned with roentgen treatment, the observation of which would lead to a considerable elevation of the standard of roentgen therapy throughout the country.

Train Your Hearing: Lessons for Home Practice. By Mary Wood Whitehurst. Cloth. Price, \$3. Pp. 80. The Volta Bureau, 1537 35th St., N. W., Washington 7, D. C., 1947.

A hearing aid does not always solve the problem of deafness. Persons with poor vision can tell immediately that they are seeing better, but the hard of hearing person needs patience to learn how to use the hearing aid to best advantage.

This book outlines a method of self training which is intended to "help re-educate one's residual hearing." Although self training is not as good as that obtained from skilled persons specializing in the field, some who are hard of hearing can be helped in this way. The author has described the experience of the armed services in their retraining of service personnel deafened while on duty.

This book suggests a system which will assist hard of hearing persons in auditory training by providing a list of words and phrases and instructions on their use. The author also suggests phonograph records (music and singing) to be used in auditory training. This volume is of particular interest to the otologist because he can recommend to his patients methods of developing dexterity in using the hearing aid.

Cardiopatologia: Elementi di semeiotica, diagnostica e terapia delle malattie cardiovascolari. Di A. Massimo Michelazzi, docente di patologia e di clinica medica incaricato di semeiotica medica nella Università di Pisa. Prefazione del Prof. Francesco Galdi. Fabrikoid. Price, 1500 lire. Pp. 469, with 85 illustrations. Rosenberg & Seller, Via Andrea Doria, 14, Turin 3, 1947.

The title of the book is misleading, as it deals mainly with the clinical signs, symptoms, and treatment of the diseases of the heart and of the peripheral blood vessels. The book is intended for the practitioner and the description of modern cardiologic methods of investigation is greatly simplified. The attempt is sound, but some of the physiologic views are far behind the times, as proved by the admission of a "tonus" of the heart and by the statement that adrenalin is the sympathetic mediator. Some clinical observations are not in agreement with general experience. Many chapters, as that on hypertension, in which the responsible factors are barely incompletely outlined, give the impression that the material was assembled somewhat hastily.

Your Community: Its Provision for Health, Education, Safety, and Welfare. By Joanna C. Colcord. Revised by Donald S. Howard, Director of the Department of Social Work Administration, Russell Sage Foundation. Third edition. Cloth. Price, \$1.50. Pp. 263. Russell Sage Foundation 130 E. 22nd St., New York 10, 1947.

"Your Community" was first published in 1939. It was revised in 1941 and again in 1947. Actually the manual is designed to assist persons or organizations in the study of community services and facilities. The manual tells how to study the health, education, safety and welfare status of any community, whether a township, borough, city or county. Although not intended as a guide to technically equipped surveyors making special social evaluations, it does give a wealth of background from which the interested citizen may organize his thoughts on community problems.

The Causation of Appendicitis. By A. Rendle Short, M.D., B.S., B.Sc., Professor of Surgery, University of Bristol, Bristol, England. Cloth. Price, \$2.50. Pp. 79, with 4 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

Dr. Short admits that a readily identifiable cause is not apparent in the great majority of patients with appendicitis. He suggests that diet may have much to do with establishing the disease, that when the intestinal contents lack cellulose they are too fluid and too readily enter the appendix where they dry and form fecoliths which eventually produce obstruction.

Such a bare outline does not do justice to the work that went into the preparation of this booklet or to the attractive manner in which its arguments are presented. How often did appendicitis occur in ancient times? In Elizabethan days did the two "honest and discrete matrons within every parish who shall be sworn truly to search the body of every such person as shall happen to dye within the same parish, to the end that they make true report to the clerke of the parish of all such as shall dye of the plague," know appendicitis? Did they record it on their death reports under such awe-inspiring names as "surfet," "plague in the guts" or "stoppage of the stomach?" What was the cause of King Stephen's death after he was suddenly seized with the "iliac passion" and with an old disease of the "emrods?" Why is it in the West Indies, or at the Johns Hopkins Hospital for that matter, that appendicitis is seen with relative infrequency in Negroes? Why is it that the Eskimos and the Chinese and the Orientals and the Arabians seem to have it but rarely? Why is it so common in the United States?

Dr. Short thinks that the incidence of appendicitis increases when races or people refine their dietetic habits and no longer use foods containing more than traces of cellulose. He defends his hypothesis adroitly. Anyone who enjoys a well written medical disputation will add this volume to his library with great pleasure.

Milk and Food Sanitation Practice. By H. S. Adams, B.Sc., Chief, Bureau of Environmental Hygiene, Division of Public Health, Minneapolis. Cloth. Price, \$3.25. Pp. 311, with 65 illustrations. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

The author outlines with descriptive tables and illustrations the duties and obligations of the control officer in the field of environmental sanitation. The text includes introduction of the health officer, public health engineer and food sanitarian to the problems of milk and food control. Need for effective educational programs is properly emphasized. Basic research in the essentials of restaurant and soda fountain sanitation are under way in many places at present. The author has done a timely job in bringing together factual data which can be supplemented as reports of current research become more widely available. The book is commended to every health officer and student of sanitation.

Professional Relationships of the Nurse. By Helen F. Hansen, R.N., M.A., Executive Secretary, Board of Nurse Examiners, Department of Professional and Vocational Standards, State of California. Second edition. Cloth. Price, \$3. Pp. 427. W. B. Saunders Company, West Washington Sq., Philadelphia 5, 1947.

Student nurses should become properly aware of their personal responsibilities and relationships to progress in their chosen field.

Considerable revision of the second edition of this book has been made. Primary changes relate to trends developed during World War II. The development of industrial nursing as a specialty field and the development of topics for study which will lead the student into a still broader understanding of her professional relationships are two of these.

Students are provided with an informative discussion of the organizations and services of the nursing profession at the local, district, state, national and international levels. They are also assisted in making a choice among fields of specialization in nursing.

The title, "Professional Relationships of the Nurse," is somewhat misleading, as it indicates that relationships of nurses with other professional personnel receive attention in addition to relationships among nurses. The weakness of the book lies in this lack of emphasis on the nurse as a member of the medical team.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EDEMA FOLLOWING SUNBURN

To the Editor:—I have seen 2 cases of disabling edema following modern sunburns. A man, aged 25, developed pitting edema of the lower extremities after only thirty minutes exposure to the sun. After about ten days he still has a 2 plus pitting edema, which has been gradually receding. A woman aged 24 developed pitting edema of all areas exposed to the sun but most severe in the lower extremities about twenty-four hours after a two hour exposure. The discomfort from the edema in the lower extremities has been severe enough to confine her to bed. At the end of the third day of illness there has been only slight improvement. Both patients received their exposure on the coast of North Carolina. The woman gives a history of hay fever, allergen unknown. Neither gives history of previous edema. Please advise as to the pathologic physiology involved and recommended treatment.

Lieutenant, M. C., Fort Bragg, N. C.

ANSWER.—Edema following sunburn is probably caused by histamine released from damaged basal cells of the epidermis. There are wide variations in individual sensitivity to ultraviolet. Blondes are more sensitive than brunets, people with hyperthyroidism or hypertension are more sensitive, menstruating and pregnant women are more sensitive. An acidic diet is said to increase sensitivity, and the sensitivity of individuals with congenital or acquired porphyria is well known.

Thus it is possible in a very sensitive person to have minimal burning with considerable systemic reaction.

In addition to purely symptomatic treatment and general measures ordinarily employed for the edematous conditions, the use of one of the antihistamine preparations such as "benadryl" or "pyribenzamine" might be of benefit. Aside from these there are no specific therapeutic measures for this type of edema.

TRANSIENT VARICOSITIES

To the Editor:—For the past two years a man aged 43 has had veins enlarge on the left side of the tongue and then return to normal. At this time it is painful for two or three days. The history is negative except that appendectomy was performed three years ago. The veins that enlarge are nearly on a level with the lower part of the teeth. The teeth are not bad and the tonsils are normal. The patient's health is very good. Can you help me as to cause and treatment?

George C. Stimpson, M.D., Poy Sippi, Wis.

ANSWER.—The lesion fits the description of transient varicosities. They may be unilateral, recurring and subsiding, and produce a "direct objective pain" over a period of two years. The cause is usually a direct irritation of the area by smoking, food, drink or drugs. Smoking may especially tend to produce such an effect. Repair of the teeth at a time near the onset of the symptoms would lead one to suspect an electrical irritation from amalgams of different composition. A remote cause might be an obstruction or abnormality of innervation of the vessels; the cervical area should be carefully examined for such a possibility. Treatment should consist in finding and removing the cause. A dilute astringent mouth wash may allay the symptoms.

AIRSICKNESS AND EARACHE

To the Editor:—Please forward information on precautionary measures against airsickness and earache in long flights involving four or five days in the air with occasional landings.

S. C. Lynn, M.D., Savannah, Ga.

ANSWER.—To avoid ear discomfort due to inadequate eustachian tube ventilation, avoid flying during a common head cold or an active allergic rhinitis. When the ears feel full during ascent or descent, swallowing a few times ordinarily relieves this feeling. If stiffness is not relieved, chewing gum and attempting to yawn may succeed in opening the tubes. The upright position with the head slightly extended on the neck favors opening of the tubes. If this is unsuccessful, close both nostrils and puff out the cheeks. The increased pressure may force the tubes to open. If trouble is anticipated, either a "benzedrine" or a "uamine" inhaler may be used to constrict the nasal and nasopharyngeal mucosa about twenty minutes before descent. Opening of the tubes either by swallowing or by autoinflation is thereby facilitated. On some of the planes the

stewardess is prepared to furnish a small balloon with a nasal tip for this purpose. The balloon is inflated with one nostril while the other is held closed. If simple inflation of the balloon doesn't open the tubes, the swallowing act is then carried out, the inflated balloon still being connected to the nose. This allows the increased air pressure in the balloon to act at the eustachian tube orifice at the moment when the muscles which tend to open the tube are in contraction. The latter device can be easily constructed by tying a small toy balloon onto a glass nasal tip.

Air sickness can sometimes be prevented by atropine-like drugs taken an hour or two before the plane trip. One mg. of atropine or 1 mg. of hyoscyamine taken by mouth has been found to be of value. A combination of such a drug with a barbiturate is claimed to be a little more effective.

EXCRETION OF ESTROGENS DURING PREGNANCY

To the Editor:—Please give me the amounts in rat units, international units or milligrams of estrogen, progesterone and chorionic gonadotropin during pregnancy by the month if possible.

M.D., Texas.

ANSWER.—In the early phase of pregnancy the excretion of estrogens rises slowly from normal values found in the menstruating woman, so that at about the eighth week there is from 2,000 to 10,000 international units of total estrogens. The values then increase gradually to from 15,000 to 40,000 or even more international units at term. Immediately before delivery estrogens decrease precipitously to very low levels. It should be understood that these estrogens are in the free and combined form, predominantly the latter, which can be tested biologically only after hydrolysis to the free or active form. Pregnanediol excretion is at a relatively low value up to about the third month, ranging from 5 to 25 mg. daily. There is a rather steep rise in daily excretion to about 100 to 150 mg. during the last few months of gestation, and a steep drop a few days before term to low values approaching those of the normal luteal phase (4 to 15 mg.). Chorionic gonadotropin excretion differs in pattern from the foregoing two substances. The hormone appears fairly promptly in the urine in increased quantities, so that it can be detected two weeks after the missed period by the injection of urine into rabbits (Friedman test). These values range between 1,000 and 5,000 rat units daily. By the thirtieth day, however, there is a definite explosion in excretion, approaching 100,000 rat units in twenty-four hours, and on about the fortieth to the sixtieth day there may be even a higher concentration up to 800,000 rat units daily. Following this sharp peak in excretion there is a gradual decrease to a fairly constant level of 5,000 to 10,000 rat units daily until term, when a further drop to an inappreciable amount occurs.

TWO VARIETIES OF HYPOGLYCEMIA

To the Editor:—Is there anything new in the treatment of idiopathic hypoglycemia? My patient is only fairly well controlled by frequent carbohydrate ingestion and often requires intravenous glucose. He is 42 years old, and his glucose tolerance curve is very low. Has partial pancreatectomy been attempted?

Lawrence R. Medoff, M.D., Grayville, Ill.

ANSWER.—There are two distinct varieties of hypoglycemia. One is caused by organic disease, such as islet cell tumor, insufficiency of the adrenal cortex, pituitary insufficiency or advanced hepatic insufficiency. In organic hypoglycemia the symptoms almost invariably are precipitated by fasting or exercise, are accompanied by a pronounced reduction of the value for blood sugar (usually to 50 mg. per hundred cubic centimeters of blood or less) and are relieved by the intravenous administration of dextrose. There should be a history of previous autonomic and emotional stability. If these criteria are satisfied and if hepatic and adrenal disturbances are eliminated, the patient should be advised to undergo surgical exploration of the pancreas. If a pancreatic tumor is not found, partial pancreatectomy could be done. The minority of islet cell tumors are found in the head of the pancreas. The possibility of diffuse islet cell hyperplasia is most remote; in most instances a tumor will be found if the search is careful enough. Resection of the rest of the pancreas may be necessary if symptoms persist. The possibility of malingering, involving the injection of insulin, should not be forgotten. Alloxan and radioactive zinc are being studied, but no conclusions have been reached concerning their effectiveness in treatment of islet cell tumors.

Second, there is the type of hyperglycemia associated with nervous tension and neurosis. Symptoms arising from this

variety are correlated with only a moderate lowering of the value for blood sugar. They usually occur two or three hours after meals. Such persons generally withstand the diagnostic fast of forty-eight to seventy-two hours without the development of pronounced hypoglycemia. To concentrate on their "obscure metabolic" disturbance is poor therapy since that attitude on the part of the physician serves to intensify an already existing anxiety. Surgical exploration is of no value to such patients. Reassurance and psychiatric therapy are of the greatest value. A diet relatively high in protein, with between-meal feedings as needed, often is of value. It should be explained to the patient that he has no organic illness and that the diet is secondary in importance to the solution of his emotional difficulties or to the acceptance of his unfortunate constitutional or biologic condition.

David has written concerning partial pancreatectomy in hypoglycemia. Whipple's paper should be consulted by any one concerned with this problem. Whipple believes the glucose tolerance curve is of little help in the differential diagnosis of hypoglycemia.

CONTROL OF ASCITES IN CIRRHOSIS OF LIVER

To the Editor:—I have a patient who has cirrhosis of the liver and whom I have had to tap three times in the past two months. At each tapping a large amount of yellow watery fluid was obtained. The laboratory analysis did not show anything abnormal. I have been considering several procedures that would make it unnecessary to do frequent paracenteses. I understand that there is supposed to be a glass button to be embedded subcutaneously to help the tissues absorb this ascitic fluid. There is also the operation of omentopexy, which helps absorption of the fluid by collateral circulation. Also I have been advised that sometimes removal of the spleen helps in these cases. I would appreciate some information on this matter. The patient's condition has improved considerably since he has had these paracenteses.

M.D., Missouri.

ANSWER.—It is difficult to avoid performing paracentesis frequently on patients who have the ascitic or "decompensated" form of cirrhosis, since no entirely satisfactory surgical method of control has been devised. Omentopexy has been largely discarded, general experience indicating that it carries a high risk and accomplishes little. In 42 per cent of the 38 cases described recently by Cates, in which omentopexy was done for the relief of ascites, death occurred within two weeks after the operation (Cates, H. B.: Surgical Treatment for Cirrhosis, *Arch. Int. Med.* 71:183 [Feb.] 1943). Other procedures calculated to drain ascitic fluid into peripheral veins (Ruotte) or the renal pelvis (Ferguson) have not been generally accepted. Crosby and Cooney (*New England J. Med.* 235:581 [Oct. 17] 1946) have revived interest in an old procedure, that of inserting a hollow glass button within the lower part of the sheath of the rectus muscle and by this means connecting the peritoneal cavity and the subcutaneous tissues. This allows for a sort of hypodermoclysis of ascitic fluid into the patient's tissues and has the merit of saving protein which would otherwise be lost. This method of approach deserves further trial.

A more radical approach to the problem of ascites has been suggested by the work done recently at Whipple's clinic in which portocaval anastomosis has been performed by uniting either the portal vein to the vena cava (Eck fistula) or the splenic and renal veins. Designed primarily to relieve portal hypertension, this operation also relieved ascites in some of the cases described by Blakemore and Lord.

In the main, most clinics which have to deal with numbers of patients who have ascitic cirrhosis have preferred to control ascites by occasional tapping and have placed their principal reliance in medical measures designed to improve hepatic function. These include dietary and vitamin therapy and such accessory measures as the administration of choline, methionine, protein hydrolysates, liver extract given intravenously and human serum albumin. These measures have been outlined in recent issues of THE JOURNAL (April 19, 1947, page 1181; June 21, 1947, page 673). Until these have received an adequate trial, the surgical measures mentioned could best be deferred.

SICK PETS

To the Editor:—As the family doctor I have been called on to put injured and sick pets, such as cats and dogs, out of their misery. On one occasion I used 2 grains of morphine and that took too long. After that I got some potassium cyanide, which caused convulsions and took about five minutes. To keep face with the next family I should like something prompt and painless. Please advise.

M.D., California.

ANSWER.—The following is recommended by a well known veterinary authority: 259.2 Gm. of pentobarbital sodium, 200 cc. of 95 per cent alcohol and sufficient isotonic solution of sodium chloride to make 2,000 cc. One cc. to 5 pounds weight.

MEMORY DEFECT FOLLOWING SHOCK TREATMENTS

To the Editor:—A man aged 38 became very nervous and agitated in January 1946. During the war years he was extremely overworked. Previously this patient was always congenial and emotionally stable. He was far above average intelligence and had a keen memory. He held a very responsible position and was a leader in the community. He was advised to consult a psychiatrist, who suggested electroshock therapy. He was given between fifteen and twenty electroshock treatments, which seemed to improve his agitation. While at the sanatorium he had difficulty in sleeping and was given 12 grains (0.78 Gm.) of sodium amylal nightly for sleep. On returning home he took 6 grains (0.4 Gm.) of secobarbital each night for sleep. This sedation did not improve his sleeping and he discontinued using it. For the past year his family advises me that he has been sleeping from two to three hours a night. After the patient left the sanatorium he returned to work but because of partial loss of memory he became emotionally upset and lost confidence in himself. He was told that as a result of the shock therapy his memory would be temporarily affected but that it would return to normal. The patient was eventually forced to quit work. He has had no further electroshock therapy but he still has a partial memory defect. Some events and names he cannot recall. "During all this period the patient has been very rational throughout. I am anxious to help him. Is it possible that his memory will still return to normal? Has the patient received too much electroshock therapy? Could these symptoms be due to disturbances of the male climacteric? The patient is in good physical condition. Could you suggest anything in the way of treatment? His memory of events since his shock treatment is normal. He still is emotionally upset.

M.D., Washington.

ANSWER.—Ordinarily the memory defect produced by fifteen or twenty electroshock treatments is circumscribed and ceases to be noticeable after thirty to sixty days following treatment. Barbiturate drugs may produce a circumscribed memory defect also. If the mental symptoms continue after treatment—and it must be remembered that electroshock treatment is not always successful—the patient may worry excessively about the memory defect and magnify its importance. He may do this also as a defense against having further treatments or against returning to work with which he feels unable to cope while ill. In other words, a patient with a depression (melancholy, ideas of inefficiency, slowed mental processes, difficulty in reaching decisions, difficulty in concentration) may be sick much longer than one year and still recover. The amount of shock treatment does not seem to have been excessive. It is unlikely that he is passing through the male climacteric. As his memory for events since the shock treatment is normal, it is also unlikely that the trouble is caused by any progressive organic brain disease. Sometimes amphetamine sulfate 5 to 10 mg. twice each morning helps recovery of memory for recent events and serves as a stimulant emotionally.

HOUSE DUST ALLERGEN

To the Editor:—Is "autogenous" house dust superior to stock commercial house dust desensitizing preparations?

Victor H. Boogdanian, M.D., New Brunswick, N. J.

ANSWER.—The nature of the house dust allergen has not been satisfactorily established. Most investigators agree that house dust consists of a combination of many of the common environmental substances found in a home together with incidental organic materials. Some believe there is in addition a specific factor in house dust which is not related to any of the known environmental materials causing allergy. This specific factor has not been identified, although house dust has been used for about twenty-five years in the treatment of respiratory allergy.

Generally a stock dust preparation made by obtaining house dust from a number of homes, preferably of patients with respiratory allergy, is satisfactory in the majority of cases of sensitivity to house dust. One must make certain that the preparation does not act as a primary irritant but is definitely allergenic. There are occasional patients in whom a preparation made from the dust of the individual's own home ("autogenous") gives better reactions than the stock dust preparation. This may be due to a relatively excessive amount of one or more of the allergens in the preparation to which the patient is selectively more sensitive; i. e., if a patient is more sensitive to feathers and kapok than the average person and his environment contains an excessive amount of feather dust his "autogenous" dust preparation may be a more effective material than the stock solution. It is therefore a good rule that if a patient who has symptoms that are suggestive of house dust sensitivity (increased symptoms while at home, especially during the winter months) has a slight skin reaction to the stock house dust preparation, a solution made from the dust of the patient's own home is justified. The routine preparation of "autogenous" solutions in every suspected house dust case is neither advantageous nor necessary.

WOMEN WHO CONTINUE TO BLEED POST PARTUM

To the Editor:—I have had an obstetric patient who "spotted" daily for as long as ten weeks after delivery. She delivered an 8 pound 7 ounce (3,827 Gm.) boy spontaneously, with a second degree perineal tear resulting. The placenta was expelled spontaneously without undue traction and appeared to be intact on inspection. The cervix was not inspected. The duration of labor was within normal limits. About one-half hour after delivery the patient had a "heavy flow," which was controlled by a second ampule of ergonovine, the first having been given at the completion of the third stage. When the patient was discharged the tenth day after delivery the uterus was still palpable 1 to 2 fingerbreadths above the symphysis. The bleeding stopped for two to three days, but after resumption of activity the patient would soil one pad a day. At the sixth week post partum, the cervix was baggy and showed several lacerations. The fundus was not unduly enlarged but was in a position of second degree retroversion. The cervix was treated once a week with an application of silver nitrate. Blood count at the end of seven weeks showed hemoglobin 1.5 and erythrocytes 3,750,000. I should like to ask the following questions: Is it common practice to permit these patients to spot until one or even two menstrual periods have occurred? Provided the patient does not have a sudden severe flow, when, in your opinion, is the proper time for dilation and curettage or cervical cauterization? Should a patient with subinvolution be discharged from the hospital? Should she be discharged as long as she has any bleeding? Please include any forms of local therapy you have found to be beneficial.

M.D., Pennsylvania.

ANSWER.—Women who continue to bleed or spot after having had the first postpartum menstrual flow should be curetted. Cervical cauterization should not be performed until after four months from the time of delivery except when the cervix is the source of bleeding. First, silver nitrate or other medicament should be tried to control the bleeding and if this is not successful the electric cautery should be used. Caution must be exercised in the use of a cautery early post partum because pelvic infection has followed such a procedure. A patient with subinvolution may be permitted to leave the hospital provided she is not bleeding, but she should be told to take fluidextract of ergot or an ergonovine tablet four times a day for four or five days. If the subinvolution is associated with the escape of bright colored blood or an unusual amount of dark blood, the patient should be kept in the hospital resting in bed and taking ergot or ergonovine. If the bleeding is profuse in the first few days post partum and is not controlled by bed rest and medication, a curettement should be done.

CARDIAC FAILURE IN CHILDREN

To the Editor:—There has been a great deal of controversy concerning digitalization of rheumatic cardiac patients in failure. I would appreciate a complete outline dealing with therapy for the rheumatic cardiac patient in failure. I refer to pediatric cases. Will you include rapid and slow methods of digitalization? Harry W. Orris, M.D., Brooklyn.

ANSWER.—Heart failure due to rheumatic fever in childhood practically always results from active rheumatic infection involving the myocardium. On this account the management of cardiac failure in childhood differs from that in the adult. Digitalis should rarely be the first weapon employed. Complete rest in bed, sedation, oxygen and the use of diuretics may be sufficient to relieve the patient's symptoms.

In instances of acute rheumatic pericarditis, digitalis seems to be almost useless. In the more chronic cases, in which slowly progressive congestive heart failure occurs, digitalis often proves to be of great value.

The amount of digitalis necessary to secure digitalization is roughly $1\frac{1}{2}$ grains (0.1 Gm.) for each 10 pounds (4.5 Kg.) of body weight. Although rapid digitalization is seldom necessary, it may be achieved by administering half of the required dose initially and then one fourth of the remainder at six hour intervals, thus completing the total dosage in twenty-four hours. Except in an emergency, the required amount should be spread over a period of two or three days. The daily maintenance dose is about one fifteenth of that required to secure digitalization. The oral route is usually satisfactory. If vomiting is present, digitofoline or a similar preparation can be used intramuscularly or intravenously.

Children show wide variations in their tolerance to digitalis. They may show toxic symptoms from amounts computed according to the outline suggested. More often they require doses larger than those given as standard for a given weight. In any event the child must be carefully watched during the entire time digitalis is being administered. Nausea, vomiting, extrasystoles, dropped beats or excessive slowing of the heart point toward overdosage. Frequent electrocardiograms aid in showing early digitalis intoxication. When signs of poisoning occur, the drug should be withdrawn for a few days, and smaller doses employed thereafter.

In auricular fibrillation, digitalis is highly beneficial. This condition is infrequent in children and occurs chiefly in children with extreme myocardial damage. Though great temporary benefit may result, the very presence of auricular fibrillation portends a fatal termination in a matter of months or at most within a few years.

NO BASIS FOR USE OF DESICCATED KIDNEY SUBSTANCE

To the Editor:—Please discuss the use of desiccated kidney substance in the treatment of kidney diseases. M.D., Puerto Rico.

ANSWER.—There is no basis, in the present state of our knowledge, for the use of desiccated kidney substance in the treatment of kidney diseases. The experimental trial of various extracts of the kidney in the past has been done in the hope of improving renal excretory function or as a means of lowering the blood pressure in hypertensive disease. The evidence for the former action has been entirely unsatisfactory if one eliminates effects due to the various vasodilator components of many tissue extracts. The antipressor effect of kidney extracts orally administered is difficult, if not impossible, to demonstrate in man, although there is evidence for effectiveness in the hypertensive rat.

It will probably be a long time before dried kidney achieves the results claimed for it by certain unscrupulous pharmaceutical dealers, one of whom used to advertise that his brand contained both the internal and external secretions of the kidney.

UNABSORBED BISMUTH SALTS

To the Editor:—Eight years ago a patient came under my care suffering from secondary syphilis. Antisyphilitic therapy consisting of alternate courses of nearsphenamine and bismuth salicylate was given continuously for one and one-half years. The patient is in good health and is clinically and serologically free from evidence of syphilis. X-ray of the pelvis shows infiltrations of bismuth in the gluteal muscles. Is there any form of treatment that will cause absorption of this salt? Will it ever be absorbed if simply left alone? Stanley J. Simmons, M.D., Louisville, Ky.

ANSWER.—Bismuth salts injected intramuscularly usually are reasonably rapidly absorbed. However, their presence may be detected many years later by x-ray examination. In one case, for example, such shadows have been seen after more than seventeen years. The reason for this shadow, aside from the fact that it may be bismuth, could be that bismuth deposition has excited a focus of calcification, or, as is known to occur after injections of bismuth hydroxide, an insoluble bismuth soap may have formed. It is obvious that, short of excision of these injection sites, no treatment is of avail. Except for occasional embarrassment to the patient in whom bismuth shadows might be found when x-ray examinations are made in the region of the deposit, no real harm will result.

EFFECT OF ESTROGENS ON BLOOD PRESSURE

To the Editor:—Please discuss the effect of estrogens on hypertension, hypotension and normal blood pressure. M.D., Syracuse, N. Y.

ANSWER.—There appears to be little direct effect of estrogens on the blood pressure of human beings when administered in therapeutic doses. An indirect effect is obtained, however, in patients with hypertension in whom an increase in blood pressure results from nervous tension and emotional instability associated with menopausal symptoms. Relieving the patient of such symptoms by estrogens will often cause appreciable drops in the blood pressure to more normal levels. There may also be a correction of hypotension with the patient under therapy with similar substances, but to a less dramatic degree. Little if any effect is encountered on normal blood pressure however, except for the possibility that when the administration of estrogens is excessive it produces nervous tension similar to that encountered during the premenstrual phase of many women. This reaction is transitory and lasts for only a few days following the administration of the estrogen.

CLIMATE AND THE BLOOD COUNT

To the Editor:—The statement is often heard that a person's blood becomes "thicker" in a cold climate and "thin" in a warm climate. A patient of mine returning from the Dutch West Indies quotes physicians there as confirming this statement. Is there any difference, normally, in the hemoglobin and blood count of a person living in a cold or hot climate? S. Willard Haley, M.D., Houston, Texas.

ANSWER.—There are no reliable data which would indicate that characteristic changes occur in the blood counts of persons living in cold climates as compared with those living in hot climates.

RECENT ADVANCES IN THE TREATMENT OF VIRAL AND RICKETTSIAL DISEASES

THOMAS M. RIVERS, M.D.
New York

Brilliant results obtained in the therapy of certain bacterial and spirochetal diseases by the use of chemical agents and antibiotics emphasize the absence of similar successes in the treatment of viral and rickettsial diseases. This difference between the response of bacterial and spirochetal diseases on the one hand and viral and rickettsial diseases on the other to chemotherapy is probably due to fundamental differences in the nature and metabolic activities of the two groups of disease-producing agents.

Although nothing similar to the therapeutic results obtained with bacterial and spirochetal diseases can be pointed to in the viral and rickettsial field, sufficient evidence has been obtained to warrant the hope that eventually chemotherapeutic agents and antibiotics will be found effective against maladies in the latter group. For instance, Meiklejohn and his associates¹ and Wiseman and his associates² have reported that penicillin and sulfadiazine have some therapeutic value when used against certain strains of viruses in the psittacosis-lymphogranuloma group. Greiff and Pinkerton³ have shown that experimental rickettsial infections are somewhat susceptible to the action of penicillin, while other workers⁴ have found them to be susceptible to para-aminobenzoic acid and nitroacridine. It has also been shown that nitroacridine has an inhibitory effect on the growth of influenza B virus in embryonated eggs.⁵

From the Hospital of the Rockefeller Institute for Medical Research. Read in a Panel Discussion on Recent Advances in Treatment before the joint meeting of the Section on Internal Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

Fitzgerald and Lee⁶ found that "phosphine GRN" (2-amino-9 [*p*-aminophenyl] acridinium chloride) effectively inhibits the multiplication of a bacteriophage in infected suspensions of *Escherichia coli*. This inhibition is counteracted by ribonucleic acid, a result which suggests that some cellular mechanism involving nucleic acid or related substances is essential for the multiplication of the bacteriophage. According to Cohen and Anderson,⁷ 5-methyl tryptophane inhibits multiplication of *E. coli* B without apparent effect on the rate of its oxygen utilization in a synthetic medium. *E. coli* organisms infected with bacteriophage T2 or T4 do not support the reproduction of the viruses while in the presence of 5-methyl tryptophane, a substance which has no deleterious effect on the bacteriophages exposed to it in the absence of bacteria. While bacteriophages do not multiply in bacteria in the presence of 5-methyl tryptophane, they are able to do so when it is removed from the bacteria by dilution. Horsfall and McCarty⁸ have shown that several polysaccharides, such as those obtained from *Klebsiella pneumoniae* and *Streptococcus MG*, have a therapeutic action in mice suffering from pneumonia caused by a virus designated as PVM (pneumonia virus of mice). This pneumonia can be produced only by intranasal introduction of the virus, and the polysaccharide, if a therapeutic effect is desired, also must be introduced intranasally. The maximum multiplication of the virus in the lungs is reached on the sixth or seventh day, at which time most mice die. Polysaccharides introduced as late as the fourth day after infection will protect the animals from death. While the virus is not inactivated by the polysaccharides, it is unable to multiply in their presence. Takahashi⁹ has reported that a polysaccharide from yeast inactivates tobacco mosaic virus and believes that the inactivation is brought about through a reaction between the polysaccharide and some group in the virus particle which is essential for its infectivity. Other workers, however, are of the opinion that the yeast polysaccharide produces the observed results by action on the host cells instead of on the virus. Snyder¹⁰ has emphasized the fact that para-aminobenzoic acid used in experimental rickettsial infections in embryonated eggs does not destroy or kill the

10. Snyder, J. C.: Personal communication to the author.

rickettsias already present; it merely inhibits further multiplication of them.

Sufficient examples have been cited to show that progress has been made in the treatment of experimental viral and rickettsial diseases by means of chemical agents and antibiotics. There is also evidence that penicillin and sulfonamide compounds are efficacious in the treatment of human diseases caused by viruses in the psittacosis-lymphogranuloma group and that para-aminobenzoic acid given in sufficient amounts and often enough has value in the treatment of human diseases caused by rickettsias, namely, epidemic typhus, murine typhus, scrub typhus and Rocky Mountain spotted fever.¹¹ However, according to Snyder,¹⁰ para-aminobenzoic acid is of value only when it is given early in the course of illness, because within a week sufficient damage to the vascular system of the human body has usually been accomplished by rickettsias to cause death of a patient even though no further multiplication of them takes place.

At this point it should be emphasized that, with the exception of diseases in the psittacosis-lymphogranuloma and the typhus-Rocky Mountain spotted fever groups, viral and rickettsial maladies of human beings do not respond to known chemotherapeutic agents and antibiotics. Therefore, indiscriminate use of these substances in the treatment of such diseases of man is inexcusable. In view of what has been accomplished, there is reason to believe that potent therapeutic agents for many of these diseases will be discovered. In the meantime, however, practicing physicians should be aware of the limitations of this kind of therapy with the agents already at hand. Diagnosis and treatment of infectious diseases should be based on clinical skill and laboratory precision instead of chemotherapeutic and antibiotic trial and error.

A striking feature about the results of work on chemotherapy of experimental viral and rickettsial diseases is that the viruses and rickettsias themselves are not inactivated or injured by the substances used; all that happens is that further multiplication of the disease-producing agents ceases. This is quite different from what takes place when bacteria and spirochetes come in contact with chemotherapeutic agents and antibiotics. In most instances, these micro-organisms are killed by adequate concentrations of the therapeutic substances, and their death is believed to be brought about by an interference with certain of their enzyme systems or metabolic processes. Most bacteria and spirochetes, possessing all the enzyme systems essential for growth and reproduction, are not dependent on host cells. On the other hand, viruses and rickettsias are intracellular parasites and are believed not to possess complete enzyme systems essential for multiplication. If this is true, then such systems are supplied wholly or in part by their host cells. Furthermore, if viruses and rickettsias do not have enzyme systems of their own, then therapeutic agents can have no direct, deleterious effect on them through disruption of such systems; nevertheless, their activities and multiplication can be interfered with indirectly through the action of therapeutic agents which disturb certain enzyme systems and metabolic processes of their host cells. What has just been said offers a logical explanation of why known chemotherapeutic agents and antibiotics yield

different results in different kinds of infectious diseases and indicates a practicable approach to therapeutic problems in the viral and rickettsial field.

ABSTRACT OF DISCUSSION

HEPATITIS FOLLOWING TRANSFUSIONS

QUESTION: Is there any method of preventing hepatitis following transfusions from blood or plasma?

ANSWER: As yet there is no definite means of preventing this kind of hepatitis. Dr. Joseph Stokes Jr. and his associates are conducting experiments with human globulin given at least twice at monthly intervals after the administration of blood or plasma. The evidence that globulin given in this manner is efficacious is not as yet conclusive.

NO PREVENTIVE OF THE COMMON COLD

QUESTION: Is there any hope of developing methods to prevent the common cold?

ANSWER: There are no methods at present of preventing the common cold. Of course, persons working in the field of medical research hope some day to find a means of preventing this disease.

POLIOMYELITIS

QUESTION: What can be done to prevent poliomyelitis?

ANSWER: At present no method is known by which this disease can be prevented. Vaccines are not available for use in human beings. There is doubt whether prophylaxis by means of convalescent serum is practicable. The virus is widespread during epidemic periods, being found in great quantities in the feces of patients with paralysis, patients with abortive poliomyelitis, persons with inapparent infection with poliomyelitis and many contacts. The virus is also found at times in the secretions of the upper respiratory tract. Many workers believe that the disease is spread by contact, the virus getting from feces and secretions of the upper respiratory tract of patients, etc., to the mouths of susceptible persons. If what has been said is true, it will be difficult to put into effect measures of control.

TREATMENT OF VIRAL DISEASES

QUESTION (Dr. J. Greengard, Chicago): Do human convalescent serums have an important place in the therapy of viral diseases?

ANSWER: No. By the time that a patient becomes ill of a viral infection most of the cells of that patient which are going to be infected have already become infected by the virus producing the illness. Since antibodies do not get into cells the administration of convalescent serums at this time as a rule cannot do a great deal of good.

ANTIBIOTICS AND THE COMMON COLD

QUESTION (Dr. H. Morrison, Boston): Is it worth while giving antibiotics in the common cold or influenza?

ANSWER: No.

RICKETTSIAL DISEASE

QUESTION: What is the mechanism of para-aminobenzoic acid in rickettsial disease?

ANSWER: The mechanism of the action of this drug in rickettsial diseases is not known. It is considered to influence the host cell in some manner so that the rickettsias cannot multiply. In any event, the action does not seem to be against the rickettsias themselves.

NUTRITIONAL CONTROL OF VIRAL DISEASES

QUESTION: Is it feasible to attack viral disease by nutritional control or does it take too long to bring about such influences?

ANSWER: To influence the course of most viral diseases by means of ordinary nutritional control would take too long to be of practicable value. On the other hand, it might be feasible to alter some special enzymatic or metabolic process of host cells sufficiently rapidly to influence favorably the outcome of certain viral and rickettsial diseases. Several investigators are working in this direction.

RECENT ADVANCES IN TREATMENT IN
FIELD OF GASTROENTEROLOGYH. L. BOCKUS, M.D.
Philadelphia

In the allotted time it is not possible to review all the recent therapeutic advances in the field of gastroenterology. I shall confine my remarks to those topics which have attracted most attention in both medical and lay literature. Perhaps in the question and answer period time may be afforded for discussion of other topics.

PSYCHOSOMATIC ASPECTS

A large number of patients presenting themselves to the internist and to the general practitioner for relief of gastrointestinal complaints have no recognizable organic disease in the alimentary tract or elsewhere. Furthermore, although proof is lacking to support the psychogenic origin of common gastrointestinal disorders like peptic ulcer, regional enteritis and ulcerative colitis, a careful psychologic survey on many of these patients is highly suggestive of the presence of an important psychogenic component in their illness. Weiss¹ stated, "Psychosomatic disturbances of gastrointestinal function occur in healthy people subjected to unusual emotional stress and disturbances of gastrointestinal function are among the commonest manifestations of emotional stress in neurotic people." I believe that these statements can be accepted in full and that, among some of the older physicians trained only along organic lines, too little attention is devoted to an appraisal of emotional factors in gastrointestinal disorders. The statement was made by Alvarez,² "Every gastro-enterologist who hopes to be worthy of his name and would like to cease making one serious blunder after another should be learning all he can about the psychiatry of the apparently sane. Like me, he may not have wanted to get into this field of medicine but he cannot stay out of it and be a safe internist." It is hoped that the next generation of internists will be sufficiently trained in psychiatry to appreciate the importance of psychic components in illness and that the well trained psychiatrist will continue to insist on the elimination of organic disease before concluding that the psyche is all important. This situation will exist only when the preliminary training of the psychiatrist includes training in internal medicine and when the internist by training has become something of a psychiatrist. Certainly the gastrointestinal internist to be a successful therapist must appreciate the significance of emotional factors and the part such factors play not only in functional but in organic disorders as well.

CARCINOMAS OF ESOPHAGUS AND CARDIAC
END OF STOMACH

Approximately 2,000 persons die in the United States every year of carcinoma of the esophagus.³ In 35 to 50 per cent of cases, the lesion is located in the lower

end of the esophagus.⁴ There is some statistical evidence to suggest that distant metastasis is absent in 25 to 40 per cent of patients who succumb as a result of carcinoma of the lower portion of the esophagus.

Approximately 10 per cent of carcinomas of the stomach occur in the cardiac end.⁴ Many neoplastic lesions in this region eventually extend into the lower part of the esophagus. Until recently patients with carcinoma of the lower part of the esophagus and of the cardiac end of the stomach have been regarded as having an almost hopeless prognosis, and in most instances operation was not attempted. As a result of advances in thoracic surgery and in anesthesia, together with the widespread use of chemotherapeutic agents, resection and immediate restoration of continuity have become a possibility in many patients having lower esophageal and high gastric neoplasms. By means of the transthoracic approach a number of surgeons are now resecting the lower part of the esophagus or the lower part of the esophagus and the upper part of the stomach and reestablishing continuity by doing an esophagogastrostomy in the treatment of these lesions.⁵

An expertly trained surgeon is capable of exploring the lower part of the esophagus by the transthoracic approach with an insignificant mortality. Recently Clagett reported twenty-four explorations of this type in which the lesions were found to be inoperable without a single mortality. At the Graduate Hospital, Hawthorne⁶ has opened and closed the thorax for inoperable carcinoma of the lower part of the esophagus in 3 instances without a mortality. What is the anticipated mortality when the lesion is resected? The immediate postoperative mortality in Clagett's series of 27 cases of transthoracic resection of the cardia and lower portion of the esophagus was approximately 19 per cent. The mortality in the large group of patients operated on by Sweet is now somewhere between 12 and 15 per cent. Hawthorne⁶ at the Graduate Hospital attempted transthoracic esophagectomy (lower part of the esophagus) sixteen times within the past year and a half. In 3 instances the lesion was not resectable. Three of the 16 patients died in the immediate postoperative period; 3 other patients died within two to four months; 7 patients are living from three to fifteen months after operation. It now seems obvious that some patients with carcinoma of the lower part of the esophagus and of the cardiac end of the stomach may be cured by radical transthoracic resection. It is quite possible that the five year cure rate may be as high as or higher than that encountered in radical resection for carcinoma at the lower end of the stomach. The perfection of the technic of partial esophagogastrectomy by the transthoracic approach represents a definite advance in the treatment of carcinoma in this region. Obviously every large medical center should include in its personnel a surgeon who is expert in the performance of these operations.

AMINO ACIDS IN DIET OF PATIENT
WITH ULCER

In 1942 Levy and Siler⁷ demonstrated the buffering effect of a pancreatic enzymatic hydrolysate of casein on gastric acidity. The introduction of 30 Gm. of the

amino acid mixture into the stomach caused a disappearance of hydrochloric acid in the majority of normal subjects for thirty to forty minutes. These workers suggested that amino acid mixtures might prove of benefit in the management of peptic ulcer. Co Tui and his associates⁸ (1945) reported their experience with "hyperalimentation treatment" of peptic ulcer, employing feedings of protein hydrolysates and "dextri-maltose." They stressed the value of this method in healing active ulcers previously thought to be intractable. The efficiency of the method was attributed to the buffering action of the protein hydrolysate and the alleviation of a protein deficiency presumed to be present in many of their patients. These workers deserve credit for drawing the attention of the clinician to the value of high protein feedings in the management of the patient with ulcer who is undernourished. Unfortunately, in the lay press the method was described as a new cure for peptic ulcer, and many patients have been unnecessarily subjected to the ingestion of unpalatable mixtures of amino acids as a substitute for more orthodox and usually equally efficient ulcer regimens.

Briefly, the facts concerning the usefulness of an amino acid diet formula in the treatment of active peptic ulcer are as follows:

1. The buffering action of the amino acid mixture under discussion is not uniform in all patients and the antacid value of many of the newer hydrolysates remains to be tested. There is no proof at hand to indicate that the buffering action of the protein hydrolysate administered every two hours as originally advocated by Co Tui is superior to or even as efficient as the neutralization of gastric acidity which is accomplished by the orthodox ulcer management (hourly feedings of milk, nonsoluble antacids hourly and vagus depressants). In a recent publication, Co Tui and Garcia⁹ stated that it became necessary to administer the hydrolysate mixture more frequently (thirty minutes to one and one-half hours) in order to obtain prompt relief of pain in many patients. Six of 23 patients treated by the Co Tui plan by Hodges¹⁰ required feedings more frequently than each second hour for the first few days.

2. Little is known at present of the secondary gastric secretagogue effect of various amino acid mixtures now commercially available.

3. The concept that most patients with uncomplicated peptic ulcers have a protein deficiency has not been proved. Certainly the average private patient seen in the physician's office usually shows no measurable evidence of such deficiency.

4. No objective evidence has been offered to indicate that protein hydrolysates cause any more rapid healing of a gastric or duodenal ulcer than the orthodox feeding mixture of milk (hourly) with the nonabsorbable antacids and vagus depressants.

5. The original protein hydrolysate employed by Co Tui is so unpalatable that many patients are unable to take it without disagreeable side effects (nausea, anorexia and diarrhea).

8. Co Tui, Wright, A. M.; Mulholland, J. H.; Galvin T.; Barcham, I., and Gerst, G. R.: Hyperalimentation Treatment of Peptic Ulcer with Amino Acids (Protein Hydrolysate) and Dextri-Maltose, *Gastroenterology* 5: 5-17 (July) 1945.

9. Co Tui and Garcia, E.: The Hyperalimentation Treatment of Intractable Peptic Ulcers with Protein Hydrolysates and Dextri-Maltose, *Management of Gastro-Intestinal Disease*, Philadelphia, J. B. Lippincott Company, to be published.

10. Hodges, H. H.: Protein Hydrolysate Therapy for Peptic Ulcer, *Gastroenterology* 8: 476-493 (April) 1947.

A perusal of recent publications dealing with amino acid mixtures as the keystone for treatment of active peptic ulcer supplies no convincing evidence of their superiority over milk formulas in the well nourished patient.¹¹ There is every reason to believe that reliance on these mixtures alone and ignoring of the many items utilized by the experienced gastroenterologist in all-out therapy is unfortunate.

HORMONE THERAPY IN PEPTIC ULCER

Two hormones, elaborated in the body, when injected into Mann-Williamson dogs have proved most successful in the prevention of peptic ulcer, which ordinarily occurs in approximately 98 per cent of animals so prepared.¹² One of these hormones is enterogastrone, a chalone which is released by contact of the intestinal mucosa with fat. By chemical fractionation, extracts of intestinal mucosa have been prepared by Ivy and his associates.¹³ These extracts containing enterogastrone, when injected intravenously, inhibit gastric secretion and motility, thus simulating the action of endogenously released enterogastrone. Recently Ivy and Grossman have reported the results of the daily parenteral administration of enterogastrone in dogs prepared with the Mann-Williamson operation. In 76 per cent of the dogs an ulcer did not develop during the first year after operation. In similarly operated animals, not protected with enterogastrone, death occurred on an average of 3.8 months after operation. Treatment was discontinued in 28 Mann-Williamson animals that remained alive after having had enterogastrone injections for one year. In only 2 of these dogs did ulcer subsequently develop, at eighteen and twenty-eight months after cessation of treatment. Twenty-six of the animals survived from eleven to sixty months after therapy was stopped, dying of causes other than ulcer.

A second hormone (urogastrone), recovered from urine, when injected into the experimental Mann-Williamson animal, has an effect rather similar to that of enterogastrone on gastric acidity and motility.¹⁴ This material contains an element called anthelone (anti-ulcer) by Sandweiss, which when injected parenterally also greatly reduces the incidence of experimental ulcer in Mann-Williamson dogs. Furthermore, as with enterogastrone, in the Mann-Williamson animals so treated ulcer failed to develop for long periods of time after the injections of anthelone had been discontinued. Interestingly enough urogastrone is no longer secreted in the urine after hypophysectomy, indicating that the pituitary gland is in some way concerned with its manufacture.¹⁴ It is not known at present whether enterogastrone and urogastrone are the same substance; indeed, neither of them has been crystallized.

Ivy and his associates have treated 27 patients with chronic peptic ulcer by intramuscular injection of 200 mg. of intestinal extract containing enterogastrone,

11. Hodges¹⁰ tried the Co Tui plan in 26 patients. Three obtained no symptomatic relief. There was no roentgen evidence of improvement in 3 other patients (operation was required). Five of the remaining 20 patients with roentgen evidence of improvement had a recurrence of symptoms within one to five months after termination of therapy. Only 14 patients remained asymptomatic for one to eight months.

dissolved in 4 cc. of water, six days a week. This treatment was continued for one year in 18 patients, and in 9 patients the injections were given for periods of five to ten months. In the first group 5 patients had recurrences during the treatment and 2 additional patients experienced recurrences after treatment had been discontinued—a total of 7 patients with recurrences among 18 patients treated. The authors considered this record to be much better than the anticipated results from ordinary clinical management of ulcer without enterogastrone injection, estimating that 60 per cent of patients may be expected to suffer relapses within two years after ordinary medical management. Their incidence of relapses was 39 per cent of 18 patients who had been under treatment for one year. Ivy and Grossman considered their experience as suggestive at least that intestinal extracts containing enterogastrone may prove beneficial in the prevention of recurrences in patients with peptic ulcer disease. Obviously the series of cases is too small and the follow-up too short as yet to come to a more definite conclusion. Ivy and his associates¹³ have recently stated that the oral administration of a crude extract of intestinal mucosa prevented ulcer from occurring in 75 per cent of 20 Mann-Williamson dogs and that when this treatment was discontinued the surviving animals failed to have ulcer in most cases. Up to this time there are no records of a large series of patients treated by oral administration of extracts containing enterogastrone with an adequate follow-up.

Sandweiss and his group have also been treating patients with antiulcer factors (anthelone) contained in urine extracts and have reported encouraging preliminary results. They warned against premature optimism, indicating that more purified and more concentrated extracts are needed and that a larger series of patients must be treated and observed over a long period of time before an accurate appraisal can be had. Up to this time no evidence has been forthcoming to indicate that hormones will prove of great value in the healing of ulcer. If they are to have any value in ulcer disease, evidently it will be in the prevention of recurrences.

SECTION OF THE VAGUS NERVES

How Commonly Should Vagus Interruption Be Employed in the Treatment of Peptic Ulcer Even If Its Efficacy Were Proved?—In most patients with uncomplicated duodenal¹⁵ ulcer (probably 60 per cent) an adequately arranged medical regimen results in satisfactory relief (five years or longer). Another 25 per cent have recurrences which can be satisfactorily controlled without significant economic loss or prolonged discomfort. In approximately 10 to 15 per cent the results are unsatisfactory because of obvious complications or intractability. It is only in this latter group that surgical procedures of any kind are considered. In a large number of these because of obstruction or plastering of the ulcer, vagotomy alone should not be undertaken. By these criteria, section of the vagus fibers might come up for consideration in approximately 5 per cent of ulcer patients not operated on. This would comprise almost entirely those ulcer sufferers who have strongly positive insulin reactions,

whose attacks seem related to emotional incidents and those who, in spite of a thorough understanding of the total ulcer problem, are unable to avoid severe recurrences. Even though vagus section accomplished the results expected of it, it should never be recommended until adequate medical therapy, including attention to all known etiologic factors, has been given a thorough trial—if for no other reason than the present known record that the most sanguine statistics indicate results satisfactory to the patient in not more than 80 per cent. It is unfortunate that the criteria mentioned here were not fulfilled in many instances before vagus section was so frequently performed in many clinics.

What Is the Rationale of Vagus Section for Peptic Ulcer?—It was hoped that a severance of nervous pathways between the brain and stomach would: (1) effectively abolish the cephalic phase of gastric secretion (Pavlov's experiments reported in 1910¹⁶ proved that the vagus nerves in the dog are the pathways for the stimuli which excite the psychic phase of gastric secretion); (2) reduce or abolish excessive interdigestive and night secretion of hydrochloric acid in the stomach; (3) reduce excessive motor activity of the stomach and duodenum; (4) abolish the harmful effects on the gastric circulation which might be of emotional origin (color changes in the gastric mucosa due to vascular congestion induced by resentment and anger were noted by Stewart Wolf¹⁷ prior to a vagotomy but did not occur after vagus section in a patient operated on by Andrus), and, (5) as a result of these effects on the stomach, encourage healing of active ulcer and prevent recurrences.

How Complete Must Vagus Denervation of the Stomach Be in Order to Accomplish These Anticipated Results?—It has been shown repeatedly in both animals and man that the desiderata which have been set forth may not be accomplished unless all the vagus fibers are interrupted (however, an inhibiting effect on gastric secretion and motility has been reported in some instances when the vagus denervation of the stomach has not been complete). It was in order to accomplish complete vagus denervation of the stomach that Dragstedt adopted the operation of supradiaphragmatic vagotomy.

Is Complete Interruption of the Vagus Fibers to the Stomach Always Possible?—Evidently complete interruption is not possible. Those students who have closely studied the anatomy of this region point out that variation in the course and number of vagus fibers both above and below the diaphragm is so great that it would be impossible in some instances to interrupt all the fibers.¹⁸

The accepted test for determining the presence of intact nerve fibers after vagus operations is the insulin test.¹⁹ If this test is used as a criteria of continuity of the vagus, then the most expert surgeon fails to sever all fibers at times even when the operation is

Hollander, F.: *The Insulin Test for the Presence of Intact Nerve Fibers After Vagal Operations for Peptic Ulcer*, *Gastroenterology* 7: 607-614 (Dec.) 1946.

15. Patients with gastric ulcer probably should not be exposed to supradiaphragmatic operations because of the inability to inspect the lesion and excluded carcinomatous ulcer.

performed by the transthoracic route. Three of 8 patients recently subjected to this operation by Weinstein and Colp²⁰ had positive insulin reactions after operation (however, these 3 were relieved of pain). I know of no large reported series of cases of vagus section in which the reaction to the insulin test was invariably negative after the operation.

It is this effort to sever all fibers of the vagus going to the stomach which caused surgeons to try the transthoracic approach and which has caused some to prefer actual vagus resection to simple vagotomy.²¹ I have stated that the postoperative insulin test is evidently a method of distinguishing between complete and partial vagotomy. One wonders whether the degree of delay in stomach emptying may not also measure to some extent the completeness of the vagotomy. Perhaps those patients who have had the most complete vagotomies are those whose stomachs empty most poorly or not at all after operation. I have 1 patient who was operated on Sept. 14, 1946, who up to this time (May 1947) requires "urecholine" (carbaminoyl-beta-methylcholine chloride) two to three times daily in order to empty his stomach. His reaction to the insulin test is negative; yet the hydrochloric acid titer of his fasting stomach is 90 units if no "urecholine" is taken after supper the night before.

It is because of this unphysiologic side effect of vagotomy (delay in stomach emptying) that Dragstedt and others are now looking with favor on the abdominal approach—infra-diaphragmatic vagotomy combined with gastrojejunostomy. Thus the initial thesis, that the transthoracic approach makes it possible to accomplish a more nearly complete vagotomy, is being abandoned in some clinics. In this connection perhaps it should be mentioned that there is no proof that gastroenterostomy will invariably function satisfactorily in the vagotomized stomach. This swinging of the pendulum in some clinics toward the subdiaphragmatic operation would appear to be an admission that the side effects of a complete vagotomy are undesirable. The only other valid conclusion to be drawn from this change of heart would be that the cases selected for the supradiaphragmatic operation were poorly chosen, many with associated obstructive lesions having been included.

Side Effects of Vagus Interruption.—Many physiologically minded clinicians have been concerned about the increased popularity of so-called complete vagotomy in the treatment of peptic ulcer because of possible interference with important functions of the stomach, pancreas, biliary tract and intestines. Many years ago Pavlov noted that complete vagotomy in dogs resulted in a lack of stomach emptying and subsequent death of the animals of subnutrition. Hartzell²² made no mention of gastric dilatation or faulty nutrition in his vagotomized dogs, but their survival time was not given. Complete vagotomy in rats, according to Shay and Komarov,²³ results in death of the animals within ten days if they are allowed to partake of their stock diet. The stomach and esophagus of these animals were dilated and filled with food residue. It is well

to keep in mind the statement of Necheles,²⁴ "we will have to wait for many years to know the trophic effects of section of the vagi on such organs as the pancreas, the liver, the intestinal mucosa, etc."

There is evidently little risk involved in doing the supradiaphragmatic vagotomy, judging from the reports emanating from many clinics. However, both Weeks and co-workers²⁵ and Moore and his associates²¹ have reported a death, evidently the result of cardiac standstill following vagotomy.

The most important undesirable side effects of vagus section are those due to disturbances in motility of the digestive tract. So-called achalasia or cardiospasm, to be anticipated, has not been reported frequently. Diarrhea may be troublesome. It occurred in 40 per cent of 30 patients reported by Ruffin and Smith.²⁶ Evidently it was mild and caused little inconvenience. In these same patients gastric motility was profoundly affected by vagotomy in each instance. Peristaltic waves were absent and gastric dilatation occurred. Apparently the tone of the stomach returned toward normal after several months. Subsequent gastroenterostomy or pyloroplasty was required in 3 of the 30 patients subjected to vagotomy by Ruffin and Smith. Many others have had a similar experience. Fortunately Machella and his associates²⁷ have found "urecholine" effective in increasing gastric tonus and initiating contraction waves in the atonic stomach, the result of vagotomy. The use of the drug has now obviated the necessity of reoperation in a number of instances. Evidently rather often the delay in emptying following vagotomy disappears in several months, and during this time "urecholine" may be used.

Dorsolumbar sympathectomy for hypertension should not be performed in patients who have had peptic ulcer. Blegen and Kintner²⁸ reported a patient who suffered three severe hemorrhages from a prepyloric ulcer following this operation, who was subsequently subjected to subtotal gastrectomy. Weeks and co-workers²⁵ performed a transthoracic vagotomy for duodenal ulcer and a left thoracolumbar sympathectomy for hypertension. The ulcer pain was relieved. However, fifteen days after the second stage right thoracolumbar sympathectomy, the patient died of perforation of the duodenal ulcer without having experienced pain.

An Appraisal of Results of So-Called Complete Vagotomy.—1. The cephalic phase of gastric secretion measured by the insulin test,²⁹ by sham feedings and by reduction in volume of night secretion^{29a} is either abolished or greatly diminished by intrathoracic vagotomy. The secretory response to insulin if abolished by the operation remains absent at the end of a year.²¹ However, even now there are too few published reports of satisfactorily performed insulin tests late after vagotomy to indicate that the reaction to the insulin test will remain permanently negative. It should be recalled

23. Komarov, S. A., in discussion on Symposium on Peptic Ulcer with Particular Reference to Vagotomy, *Gastroenterology* 7: 620 (Dec.) 1946.

that postprandial acidity is rarely abolished by this operation, as it is so frequently after large subtotal gastrectomy performed for peptic ulcer. The gastric secretory response to histamine and to caffeine is unaffected. Consequently, if in many instances of peptic ulcer the initiating influence is not vagal in origin, the vagotomy cannot be expected to prevent recurrences.

2. The decreased tonus and diminished amplitude of contractions of the stomach wall, noted invariably after complete vagotomy, are evidently not always lasting. The motor activity of the resting stomach was practically normal one year after operation in the patients of Moore and his colleagues. Furthermore, the extreme delay in stomach emptying experienced by many patients after intrathoracic vagotomy gradually disappears after several months, according to most observers (however, 1 of my patients must take "urecholine" daily, eight months after intrathoracic vagus resection, in order to empty his stomach and maintain normal nutrition³⁰). Obviously, as stated by Moore and co-workers, if interruption of the vagus nerves is to have a lasting effect in the prevention of recurrences of ulcer, this effect cannot be related to changes in fasting acidity or gastric motility.

3. Perhaps any lasting benefit which is to be derived from this operation may depend on an interruption of those cephalic impulses caused by emotional incidents which give rise to vascular change in the stomach (observation of Stewart Wolf¹⁷ previously cited). It remains to be seen whether this observation of Wolf will be borne out by further study and, if so, whether the desired absence of such vascular change in the mucosa of emotional origin will be permanent.

4. All observers have agreed that relief of pain is usually prompt and all evidence suggests that active ulcers usually heal promptly after intrathoracic vagotomy. It is of interest that relief of pain is not always dependent on an absence of interdigestive or cephalic gastric secretion and does not always depend on a severance of all vagus fibers (observation of Weinstein and Colp²⁰ previously mentioned). Pain initiated by an appropriate gastric stimulus can be experienced by the patient after vagotomy if a dorsolumbar sympathectomy has not been performed.

The citation of all observers that relief of pain is immediate is not the important issue here. Ulcer pain in many of these patients could have been promptly relieved by a medical regimen, including hourly feedings, atropinization and antacids. Our concern is with prevention of recurrence and cure of the disease. Recurrences of ulcer are being reported following intrathoracic vagotomy; yet up to this time they have not exceeded 10 per cent of patients subjected to operation. Too little time has elapsed to be able to state what the ultimate results will be so far as the cure of ulcer is concerned. It is clear, however, that the rate of cure will not approach 100 per cent, and it is doubtful whether the results will be any better than or as good as an expertly performed high subtotal gastric resection with or even without an infradiaphragmatic partial vagotomy.

SUMMARY

I believe that the operation of complete intrathoracic vagus interruption or resection remains an experimental procedure. A complete interruption of the vagus inner-

vation of the stomach is not always possible, and it may yet prove to be undesirable because of late side effects. Until the final results of adequate follow-up are available it should not be undertaken lightly in the patient who has not been operated on. Only patients with duodenal ulcer who have a strongly positive reaction to the insulin test and a history suggesting emotional influences in the initiation of attacks and who have not responded to really adequate medical treatment should be considered as candidates for the experiment. Gastric ulcer or delay in stomach emptying in duodenal ulcer should be looked on as contraindications. The operation should be undertaken only by surgeons thoroughly experienced in the procedure. It is not without danger. At this time, I believe that intrathoracic vagotomy can be considered the operation of choice only in those patients who have experienced recurrence of ulcer after a large subtotal gastrectomy which has included ablation of the antral and pyloric mucosa.

NOTE:—One year after vagus resection stomach emptying has improved sufficiently to permit of discontinuance of "urecholine."

ABSTRACT OF DISCUSSION

ULCERATIVE COLITIS

QUESTION: Are antibiotics useful in the treatment of chronic ulcerative colitis?

ANSWER: Most clinicians have had little success with the use of antibiotics in the chronic stage of chronic ulcerative colitis. Occasionally, a remission has been experienced during the course of administration of penicillin and of streptomycin, but in these instances there is little proof to indicate that the improvement may not have been dependent on comprehensive therapy including mental and physical rest, rather than on the so-called specific agent. Some clinicians have reported good results in the treatment of the acute fulminating febrile type of ulcerative colitis. One of these is Dr. Burrill Crohn, who administered 0.5 Gm. of streptomycin by mouth and 0.5 Gm. intramuscularly every six hours for forty-eight hours. Others have reported improvement in acute fulminating ulcerative colitis which seemed to be related to the administration of penicillin. I have had this experience in a few instances. Certainly, these agents should be tried, particularly in the fulminating stage of the disease, but all other methods of therapy should be included in the regimen with particular emphasis on the maintenance of good nutrition.

VAGOTOMY AND DUODENAL ULCER

QUESTION: Is vagotomy a satisfactory surgical treatment of simple duodenal ulcer with intractable pain?

ANSWER: I do not believe that complete vagotomy alone can be looked on as satisfactory surgical treatment for duodenal ulcer in most instances. My experience has been that if surgical treatment is necessary in duodenal ulcer, complications, particularly that of plastering of the ulcer, necessitate the more radical, large, subtotal gastrectomy. My present feeling about vagotomy is discussed in some detail in the paper.

ANTACIDS

QUESTION: What are the most effective antacids?

ANSWER: Antacids have a place in the management of many patients with peptic ulcer disease; they may be divided into (1) soluble antacids and (2) nonabsorbable antacids. The former group are not utilized to the point of causing complete neutralization of gastric acidity by most gastroenterologists today. They have lost favor because of their tendency to encourage the development of alkalosis, on one hand, and because of their secondary gastric secretory effect, on the other. However, a combination of soluble antacids including calcium carbonate, magnesium oxide and sodium bicarbonate every third or fourth hour in the active stage of ulcer management often works well.

30. See note at end of paper.

Nonabsorbable antacids are more popular at present. In this group, perhaps one could include the newer anion exchange resins and the detergents (sodium alkyl sulfate). Theoretically both of these groups of substances perhaps have the advantage of buffering the acid and reducing the peptic activity and perhaps even encourage the stimulation of mucin without having any secondary gastric secretory effect or any deleterious effect on the acid-base balance of the blood. However, insufficient clinical trials have been reported to justify the widespread use of these substances until certain disadvantages have been overcome. The most widely used nonsoluble antacids remain aluminum hydroxide gel, aluminum phosphate gel and magnesium trisilicate. The combination of magnesium trisilicate and aluminum hydroxide prepared in tablet form by several manufacturers has proved efficient in treatment of my patients.

RAPID EMPTYING OF STOMACH

QUESTION (Dr. Joseph Bank, Phoenix, Ariz.): What can be done to relieve symptoms due to rapid emptying of the stomach after partial gastrectomy?

ANSWER: This is a very difficult question because, in the first place, one must know why the stomach is emptying too rapidly, and in many instances it is the result of an improperly performed gastrectomy. Usually, I have adopted the plan of continuing the patient on frequent feedings of rather small quantities containing a rather large amount of fat, preferably in the form of cream. Furthermore, large doses of atropine or belladonna may be of benefit in these cases. Of course, in some instances some thought might be given to the gastrogenous type of diarrhea by the administration of appropriate doses of hydrochloric acid. I think that type of treatment should be held in abeyance until the dietary plan and antispasmodics have been utilized.

CURE OF PEPTIC ULCER

QUESTION (Dr. J. R. Bleich, Atlanta, Ga.): Do you think it likely that any one procedure will ever suffice to cure peptic ulcer? Or do you believe that treatment will have to be continuous throughout the life of the patient?

ANSWER: To answer this question adequately would require one hour. First, one must define what is meant by "cure." If one means the failure of slight epigastric distress to appear at any time in the future following adequate medical therapy, then one could say that perhaps not more than 25 per cent of patients with duodenal ulcer are cured by medical management. However, more nearly 75 per cent of patients who are adequately treated medically for duodenal ulcer, including advice for the prevention of recurrences, remain sufficiently well so that they suffer no economic loss and are soon relieved of their recurrences of minor distress by resuming at once a strict regimen for a brief period of time. Many of these patients can lead a fairly normal life providing they are alerted to the necessity of resuming a strict regimen at the very beginning of a recurrence.

Subtotal gastrectomy adequately performed by an expert has resulted in a large percentage of so-called five year cures, and many of these patients are leading normal lives. I think that it should be remembered that only about 10 per cent of patients with peptic ulcer disease get into really serious difficulty so as to require major operations. At this writing there is no therapeutic agent which offers a guarantee against recurrence of ulcer even though it be continued throughout life.

ENTEROGASTRONE

QUESTION: Please explain in what way enterogastrone affects healing of the ulcer? Why is it called a hormone?

ANSWER: I know of no proof that the administration of enterogastrone does affect the healing of an individual peptic ulcer. We have experimental evidence to suggest that injections of this material prevent the recurrence of experimental peptic ulcer in the Mann-Williamson animal and that, in addition for a year or more after the discontinuance of the injections of enterogastrone the animal is protected against the development of peptic ulcer. In those few clinics where the material has been used in the treatment of active ulcer, the evidence does not suggest that the material has any remark-

able effect on the healing of a particular ulcer. Both enterogastrone and urogastrone when injected parenterally into the animal inhibit gastric secretion and motility, and it is possible that some element in the crude extract may beneficially affect the gastric mucosa and encourage healing; the proof is not at hand up to this time. In referring to the question related to terminology, if "hormone" is used in its strict sense as a substance which is excitatory, then perhaps it should not be applied to enterogastrone, which is really a chalone; i. e., an internal secretion which depresses activity.

HYPERTENSION AND VAGOTOMY

QUESTION (Dr. Morris J. Levine, Miami Beach, Fla.): Does hypertension constitute a serious contraindication to vagotomy?

ANSWER: I think that one might safely say that a bilateral dorsolumbar sympathectomy may well have a deleterious effect on the patient with peptic ulcer if for no reason other than the fact that ulcer pain would not be experienced unless the serosa was involved. Ulcer complications have been reported in several cases in which both vagotomy and bilateral dorsolumbar sympathectomy have been performed on the same patient. I am not sure that proof is at hand that severance of the vagus fibers has an unfavorable effect on patients with hypertension, although theoretically one might consider that possibility. I do believe that the risk of complete intrathoracic vagotomy might be increased in patients with hypertension.

HYDROCHLORIC ACID AND PEPTIC ULCER

QUESTION (Dr. Meyer Golob, New York): Has not too much emphasis been placed on hydrochloric acid in the genesis of peptic ulcer? What about the cases of hyperchlorhydria in which ulcer does not develop and the cases of achlorhydria—admittedly ulcers develop in a small percentage? Surely vagotomy should not be singled out as the only agent to combat postoperative hypersecretory activity.

ANSWER: Obviously, hyperchlorhydria alone does not cause peptic ulcer. The hydrochloric acid and pepsin can be looked on only as the attacking force when the antiulcer factors normally present have been weakened or removed. It is true, however, that most clinicians believe that peptic ulcer cannot develop in the stomach which is incapable of secreting hydrochloric acid. I personally know of no authentic instance of active peptic ulcer in a patient who had consistently a histamine refractory achylia gastrica.

VAGOTOMY

QUESTION (Dr. Albert M. Yunich, Albany, N. Y.): What has been your personal experience with vagotomy? In the light of present knowledge, when do you recommend vagotomy?

ANSWER: That is an embarrassing question, because up to this time I have considered that vagotomy alone, when the patient has not previously had a gastrectomy, is an experiment. Three of my patients have been subjected to intrathoracic vagotomy, and 1, after operation, had a positive reaction to the insulin test and subsequently had a recurrence of ulcer symptoms, at the end of three months. The second patient was operated on last September, and the stomach has never emptied without the aid of "urecholine" since the date of that operation. His reaction to the insulin test remains negative. He is being kept as an experimental guinea pig, with his consent, because most persons believe that the motor-emptying function improves after vagotomy after a period of three, four, five or six months. It is now nine months and there has been no improvement (see note, page 297, at end of paper). The third patient has had a satisfactory result. He had a large subtotal gastrectomy, at which time the pylorus and the mucosa had also been removed. He returned with a gastroduodenal ulcer and has had a complete relief of symptoms which is now of six months' duration.

At present, I should not recommend intrathoracic vagotomy in the treatment of peptic ulcer unless the patient had previously had a large subtotal gastrectomy and unless a gastrojejunal ulcer had developed. A decision has not yet been reached concerning how many patients should have vagotomy combined with other types of gastric operation, such as gastroenterostomy or subtotal gastrectomy. It will require two

or three years before it is known just how valuable this additional procedure of vagotomy may be in the management of peptic ulcer disease, in my opinion.

USE OF HISTAMINE IN PEPTIC ULCER

QUESTION: Have you any opinion on the use of histamine in peptic ulcer?

ANSWER: I have an opinion but it is probably valueless because I have had no experience. It would not be the type of substance that I should be inclined to use in the management of peptic ulcer because of its great stimulating effect on gastric acidity.

PROTEIN HYDROLYSATES

QUESTION: Woolley has stated that the regeneration and growth factors of protein hydrolysate are not found in acid hydrolysates. Enzymatic protein digests, he said, depend on their streptogenin content, which is estimated by its ability to stimulate *Lactobacillus casei*. The physician cannot at present tell a good hydrolysate from a poor one. Do you not think that if a poor enzymatic protein digest is used the increase in oxygen-carrying power of blood is important? Toxic protein destruction present in neurocirculatory asthenia and duodenal and peptic ulcer is stopped and cured by enzymatic protein digests containing streptogenin.

QUESTION (Dr. H. N. Vermilye, New York): Why criticize protein hydrolysates which do not come up to Woolley's standard? Enzymatic protein digests, according to Woolley, depend on their streptogenin factor, which is measured by stimulation of *Lactobacillus casei*. Streptogenin factor stimulates protein synthesis from amino acids supplying this factor in toxic protein destruction—supplies a deficiency found in cases in which digestive ability cannot supply it.

ANSWER: My opinion concerning the value of protein hydrolysates in the management of peptic ulcer has been covered in the paper.

ADDITIONAL SURGICAL PROCEDURES

QUESTION (Dr. Emanuel Deutsch, Boston): Are additional surgical procedures such as posterior gastroenterostomy of benefit in recently vagotomized patients for uncomplicated duodenal ulcer when symptoms of delayed emptying time of stomach are predominant?

ANSWER: Additional surgical procedures have been used, in many instances, to overcome the delayed emptying time of the stomach following vagotomy. So far there are insufficient reports in the literature to pass judgment on the efficacy of gastroenterostomy performed for this purpose; evidently it does prove adequate in relieving the gastric stasis in many instances. However, it is highly likely that in some vagotomized stomachs even gastroenterostomy will not result in satisfactory stomach emptying. At present it seems advisable to use "urecholine," as recommended by Machella, to overcome the gastric stasis following vagotomy. This drug evidently works splendidly, and in some instances after some months the motor function of the stomach may improve sufficiently so that a subsequent drainage operation may not be necessary.

VALUE OF LIPOCAIC

QUESTION (Dr. S. J. Rugel, Philadelphia): Is lipocaic of any value in cases of hypertrophy of the liver associated with high blood fats?

ANSWER: Dragstedt and his co-workers have described two types of fatty infiltration, occurring in association with diabetes. One was attributed to uncontrolled diabetes, being characterized by a high blood lipid concentration, acidosis and relief by insulin. In the other form a low blood lipid concentration was noted, associated with impaired hepatic function, decreased secretion of dextrose and increased sensitivity to insulin. This latter type of change was relieved by lipocaic and not by insulin. I have had no experience with the use of lipocaic in cases of hypertrophy of the liver presumed to be the result of fatty infiltration, associated with high blood fats. Theoretically one would expect some benefit from the use of lipotropic substances in conjunction with a diet high in protein and low in fat.

RECENT ADVANCES IN THE TREATMENT OF CARDIOVASCULAR DISEASE

ARLIE R. BARNES, M.D.
Rochester, Minn.

Advances in the treatment of heart disease rarely can be referred to any one year. Rather they represent increments of knowledge accumulated over many years. While the treatment of cardiovascular disease is ever progressing, the efficacy of certain advances has been sufficiently well established to warrant mention of them in this summary. In recent years an encouraging number of successful procedures in the treatment of heart disease have been devised which constitute real advances.

CONGESTIVE HEART FAILURE

Digitalis.—It is customary to standardize preparations of digitalis in terms of cat units, a unit being defined as the dose of the drug that is lethal for cats. It is unfortunate that glycosides of digitalis are tested for potency by intravenous administration whereas oral administration is more common when they are used clinically. Gold¹ has shown that among preparations of digitalis there is a great variation in the degree of absorption. Whereas only about 20 per cent of preparations of the digitalis leaf or of the tincture of digitalis is absorbed in the gastrointestinal tract, practically 100 per cent of digitoxin is absorbed. It is noteworthy that only about 10 per cent of an oral dose of lanatoside C is absorbed by the gastrointestinal tract.

Since oral administration is the route of choice in giving digitalis, it is advantageous to have a drug which is absorbed completely. Digitoxin fulfils this requirement perfectly. It is feasible to administer orally a full digitalizing dose (1.2 mg.) of digitoxin with minimal prospect of gastrointestinal irritation by virtue of the small bulk of the drug required to produce the desired effect. When given orally the quantity of lanatoside C (6 to 10 mg.) or of digitalis leaf (1.2 to 1.5 Gm.) required to produce a similar effect leads to nausea and vomiting before a sufficient amount of these drugs is absorbed to produce a full digitalizing effect. Except in emergencies, it is preferable to administer less than a digitalizing dose initially and to achieve full digitalization gradually by the administration of suitable additional daily doses of digitoxin. In this way one can stop short of producing uncomfortable and sometimes dangerous toxic manifestations.

From these statements it should not be inferred that satisfactory effects of digitalis cannot be obtained by a variety of standard preparations of the drug. However, since there is a variation in the percentage of their absorption by the gastrointestinal tract, a considerable experience with a particular preparation is necessary to use it wisely.

It is seldom necessary to administer digitalis parenterally. If vomiting precludes the administration of the drug by mouth or if the situation is so grave that prompt action is required, then it is justifiable to give

a digitalis glycoside by the intravenous route. Since ouabain, when given intravenously, attains its full effect in two hours, it is the preparation of choice for quick action. An initial dose of 0.3 mg. given intravenously may be followed by intravenous injections of 0.1 mg. at intervals of two to three hours until a satisfactory effect has been obtained. It is useful to bear in mind that a dose of 3 to 5 cat units of lanatoside C, "digifolin" or digitoxin will produce a satisfactory effect of digitalis when given intravenously, but the action of these preparations is less prompt than that produced by ouabain when similarly administered.

Mercurial Diuretics.—The congestive heart failure of many patients is not adequately controlled by treatment with digitalis. It is well understood that the administration of mercurial diuretics to such patients is indispensable. It is not so well understood that mercurial diuretics are extremely useful in keeping a patient free of edema. It must be remembered that patients can accumulate 7 to 8 pounds (3.2 to 3.6 Kg.) of fluid before its presence is manifested by edema of the dependent portions of the body or by signs of pulmonary congestion. The patient may be aware of the edema because he notes the onset of dyspnea. It is useful and important to forestall the development or minimize the degree of this edema. To accomplish this, Gold² advocated the daily injection of 1 to 2 cc. of a mercurial diuretic. Since such frequent injections are burdensome to both patient and physician and since the injection often may not be needed, some more practical guide to the need for injections of mercurial diuretics should be sought. One method which I have found successful is to instruct the patient to weigh himself daily. Under standard conditions a sudden gain of 2 to 4 pounds (0.9 to 1.8 Kg.) should be a signal for him to report to his physician for an injection of a mercurial diuretic. Under such a plan it has been found that the need for injections of mercurial diuretics varies from three times a week to once in two weeks or longer, and yet the patient is protected from dyspnea or the development of more than a minimal amount of latent edema.

It should be emphasized also that the rigid restriction of salt to 1.5 to 2.0 Gm. daily has greatly diminished the need for the administration of mercurial diuretics in cases of congestive heart failure.

Restriction of Sodium and Allowance of Fluid.—Recently, Warren and Stead³ found that edema would develop in patients who had recovered from previous congestive heart failure if an excessive amount of salt was added to their diets. Under these circumstances the patients gained weight, the total volume of the blood plasma increased, the concentration of the plasma proteins decreased initially, the hematocrit determinations decreased and all of these events preceded an increase in venous pressure. Whether or not one accepts their interpretation that this failure of the kidney to excrete salt is due to the decreased output of a diseased heart and that this failure constitutes the common mechanism of heart failure, nevertheless it serves to focus attention again on the importance of sodium in the genesis of edema.

Since about the turn of the century it has been known⁴ that patients suffering from heart disease excreted sodium poorly and that the blood sodium did not increase. From these observations it was inferred that ingested salt contributed to the edema. Renewed interest in this problem was brought about by the challenging work of Schemm,⁵ who advocated a program comprised of a very large allowance of water, a sharp restriction of salt, an acid-ash diet, the use of acid-producing drugs and, occasionally, the supplemental administration of mercurial diuretics in the treatment of refractory congestive heart failure. Further studies⁶ have indicated that restriction of salt ingestion to 1.5 to 2.0 Gm. daily is the most essential feature of this program, and in a recent discussion White⁷ stated that some patients receiving such an allowance of salt remained free of edema even though their allowance of fluid was low. In a group of patients suffering from congestive heart failure who were kept on a greatly restricted intake of salt, Gorham and his associates⁸ studied the diuretic effect of increasing intake of fluid. They found that diuresis was enhanced by increasing the intake of fluid up to 3 L. a day, but beyond that, increasing amounts of fluid did not materially augment the diuresis. This evidence indicates that patients on a diet low in sodium do best when they are allowed to take as much water as they desire, up to 3 L. a day. It must not be forgotten that renal function in heart failure is compromised by a reduced cardiac output and sometimes by intrinsic renal disease. Under these circumstances there may still remain instances in which an intake of fluid in excess of 3,000 cc. daily may be required to secure a satisfactory diuresis.

HYPERTENSION

Diet.—In recent years, Kempner⁹ has advocated a diet, which is known as a rice diet, in the treatment of hypertensive states which may or may not be associated with demonstrable nephritis. This diet contains no protein of animal origin and has a content of sodium of 0.15 Gm. daily. Kempner observed objective improvement in about two thirds of the patients suffering from hypertension who were treated with this diet. Objective evidences of improvement included: a significant drop in blood pressure, a decrease in size of the heart, often definite improvement in important electrocardiographic abnormalities, a return to normal values of increased levels of nitrogen and cholesterol in the blood and a definite decrease in the changes in the retinal arteries, which are characteristic of hypertension.

Kempner¹⁰ predicted the beneficial results of this diet on the assumption that hypertension causes impair-

ment of function of the cells of the kidneys, presumably because the supply of oxygen available to these cells is decreased. As a result, the kidneys are affected by impairment of their capacity to deaminate amino acids, oxidize keto acids and form ammonia, and this failure leads to hypertension. Kempner substituted vegetable for animal proteins on the theory that the injured kidney in hypertension can no longer excrete properly the catabolic products of animal proteins. It has been calculated that 76 per cent of all the work of the kidney is spent on the excretion of urea. The concentration of urea nitrogen in the total volume of urine excreted in twenty-four hours is one fifth less in patients on a rice diet than in those on a starvation diet and, hence, the diet greatly decreases the work of the kidney.

It will be admitted by all that the rice diet is a monotonous diet. Grollman¹¹ found that the restriction of sodium results in a pronounced decrease in blood pressure in rats in which hypertension had been induced experimentally. Believing that perhaps the restriction of sodium in the rice diet was the essential factor in its beneficial effect on hypertension, this investigator and his associates¹² treated 6 patients who had hypertension by a more general diet containing animal proteins but only 0.5 Gm., or less, of sodium daily. In some of these cases they observed a striking decrease in blood pressure comparable to that observed when the more rigid and monotonous rice diet was used. These observers have not reported the effect of the restriction of sodium on the sodium, potassium, chloride and urea levels in the blood and urine for comparison with the results obtained by Kempner for patients who were treated with the rice diet.

These observations open up a new approach to the treatment of hypertension by dietary measures which deserve further study under carefully controlled conditions. Such studies should provide better agreement on the optimal composition of such a diet and should define its indications and limitations.

SUBACUTE BACTERIAL ENDOCARDITIS

When penicillin was first used in the treatment of subacute bacterial endocarditis, there were so many failures that many clinicians despaired of its usefulness. Further experience has shown that these failures were due almost entirely to insufficient doses of penicillin. The experience of Hunter¹³ permitted him to state that "the great majority of patients who have streptococcal endocarditis can be cured with sufficiently intensive administration of penicillin."

Early diagnosis is essential. The disease should be suspected in any patient with valvular heart disease who has unexplained fever for a week or more or who exhibits embolic phenomena, splenomegaly or unexplained anemia.

It is useful to establish the sensitivity of the infecting organism to penicillin *in vitro*, and in general the dose of penicillin given should be sufficient to maintain a concentration in the blood four or five times that required for inhibition of the infecting organism *in vitro*. While a dose of 400,000 to 1,000,000 units of penicillin daily will suffice in an average case, in the presence of a highly resistant strain or of relapses after

treatment, doses up to 20,000,000 units daily may be required to effect a cure.

No rule can be laid down regarding the length of time treatment must be continued, for it varies with the conditions encountered in each patient. It is seldom wise to discontinue treatment in less than three weeks. Hunter¹³ advised that treatment be stopped at the end of two to three weeks. A blood culture is then made; if this is negative, treatment is not resumed. He found that even though such a patient continues to have fever, leukocytosis, an increased sedimentation rate and embolic phenomena, it frequently turns out that a cure results without further treatment with penicillin. Such an interruption to test the question of a cure may shorten a laborious and uncomfortable treatment that otherwise might have been prolonged unnecessarily.

It is well recognized that a patient who has valvular heart disease can acquire subacute bacterial endocarditis after the extraction of a tooth and possibly after tonsillectomy. Such patients should always be protected by prophylactic treatment with penicillin. The administration of 100,000 units of penicillin every three hours for a day preceding and two days following such surgical procedures should suffice as a prophylactic measure.

ANTICOAGULANT THERAPY

Thromboembolism is a common and serious complication among patients suffering from heart failure or from acute coronary occlusion. Nay and I¹⁴ studied the condition of 100 patients during their immediate convalescence from acute myocardial infarction. Thrombotic or embolic complications were observed in 37 cases. In 4 cases such complications were the cause of death, and in 8 they contributed importantly to death. These complicating episodes included a second myocardial infarction (15 cases), pulmonary embolism (14 cases) and cerebrovascular accidents (8 cases).

Preliminary experience¹⁵ indicates that the routine administration of "dicumarol" to patients who have had an acute myocardial infarction greatly diminishes the incidence of thromboembolic episodes and promises to reduce materially the mortality rate of this condition.

The frequency with which embolism and pulmonary infarction complicate the treatment of heart failure is too well known to deserve comment. Since it is conceded generally that these emboli arise from thrombi in the veins of the legs, one group of investigators advocates ligation of the femoral or iliac veins if nonfatal pulmonary embolism has occurred. My colleagues and I have felt that we secured equally satisfactory results by treating these patients with "dicumarol." We feel that the bilateral ligation of large veins in the lower extremities is not wholly innocuous in its ultimate effects.

Pulmonary embolism occurring in medical and surgical cases ordinarily is not primarily a cardiac problem. Nevertheless, the ultimate survival of a patient who has had an attack of pulmonary embolism depends on the capacity of the heart to withstand the circulatory dis-

S.: Experiences with Dicumarol (3,3'-Methylene-bis-[4-Hydroxycoumarin]) in the Treatment of Coronary Thrombosis with Myocardial Infarction: Preliminary Report, *Am. Heart J.* 32:20-31 (July) 1946.

turbances associated with this event. If a patient has an attack of pulmonary embolism after surgical treatment and survives for a few hours, he has a 44 per cent chance of having a subsequent thromboembolic episode and an 18 per cent chance of having a subsequent fatal embolism.¹⁶ If treatment with heparin and "dicumarol" is started immediately after the episode and is administered properly, it has been shown that subsequent thromboembolic episodes can be prevented almost entirely.¹⁷ If a patient gives a history of previous thrombophlebitis or pulmonary embolism, it is feasible to preclude almost all such occurrences after surgical treatment by starting "dicumarol" therapy on the third day after operation.

A successful dosage for "dicumarol," as employed at the Mayo Clinic, is as follows: The dose for the first day is 300 mg. On each subsequent day when the prothrombin is greater than 20 per cent of normal prothrombin, 200 mg. of "dicumarol" is given. On days when the prothrombin is less than 20 per cent of normal, no "dicumarol" is given. If the prothrombin drops below 10 per cent of normal during the first few days of treatment and remains there for two days, 20 to 30 mg. of menadione bisulfite is given intravenously, and thereafter only 100 mg. of "dicumarol" is given to that patient on those days on which the prothrombin is greater than 20 per cent of normal.¹⁸

"Dicumarol" cannot be administered safely unless its dosage is controlled by daily determination of the prothrombin time expressed in percentage of normal concentration of prothrombin. If serious bleeding occurs during the administration of "dicumarol," a transfusion of fresh citrated blood should be given. At the same time, 60 mg. of menadione bisulfite should be given intravenously and this dose should be repeated once or twice daily until bleeding ceases.

"Dicumarol" is contraindicated in the presence of purpura, subacute bacterial endocarditis, renal and hepatic insufficiency or for patients who recently have had an operation on the brain and spinal cord. It should not be administered in the presence of ulcerative lesions, such as ulcerative colitis.

THE SURGICAL TREATMENT OF HEART DISEASE

Patent Ductus Arteriosus.—Patent ductus arteriosus is characterized by an absence of cyanosis, a continuous murmur over the pulmonic area and roentgenographic evidence of enlargement of the pulmonary conus. The presence of a distolic murmur over the pulmonic area is almost essential if the diagnosis is to be established by ordinary clinical methods. If any doubt obtains about the diastolic murmur, its presence or its absence may be established if a phonocardiogram can be obtained. A thrill is present over the point of greatest intensity of the murmur in 75 to 80 per cent of the cases. The pulse pressure is increased above the normal of 30 to 45 mm. of mercury. Since both right and left ventricles are subject to strain and since hypertrophy of both is common, the electrocardiogram reveals no axis deviation or only slight deviation. Pronounced right axis deviation points to some other source of predominant right ventricular hypertrophy.

The indications for surgical closure of patent ductus arteriosus are (1) stunted growth, (2) an enlarging heart or symptoms of increasing dyspnea or both and (3) the presence of subacute bacterial endocarditis. Shapiro¹⁸ urged that patients who have infected ducts should undergo early operation without waiting for a possible cure of the infection by penicillin.

Opinions differ concerning surgical intervention in cases in which the diastolic pressure is normal or only slightly reduced, in which there is little or no cardiac hypertrophy and in which there are no peripheral signs of edema. However, Keys and Shapiro¹⁹ have estimated that the life expectancy of males is reduced by about twenty-three years and that of females by about twenty-eight years if a patent ductus arteriosus remains untreated. Since the mortality rate for surgical closure of patent ductus arteriosus is 5 per cent or less, Shapiro¹⁸ is of the opinion that all children should undergo this operation as soon as the diagnosis is established regardless of apparent disability or signs of disruption of the cardiac function.

Whenever possible, section of the patent ductus arteriosus rather than ligation is the most effective as well as the most practical procedure.

Coarctation of the Aorta.—The prognosis of the adult type of coarctation of the aorta has been studied by Reifstein, Levine and Gross.²⁰ They found one group of cases in which the patients had attained elderly life, had only minor complaints and had had a reasonably satisfactory life. The patients in the second group succumbed to a superimposed subacute bacterial infection. In a third group, sudden death occurred from rupture of the aorta. In a fourth group, death occurred from cardiac decompensation or from intracranial hemorrhage. In general, they found that although some persons enjoy a long life, the prognosis usually is poor for survival beyond the ages of 25 to 30 years.

Gross²¹ in this country and Crafoord²² in Sweden have demonstrated the feasibility of the surgical treatment of coarctation of the aorta. Gross has operated on 14 patients for this condition, with 2 deaths. In 1 a satisfactory anastomosis could not be obtained, but the patient survived the operation without any significant change in his hypertensive state. In the remaining 11 cases the results of the operation were satisfactory: Normal pulsations and pressures were restored in the arteries of the legs, and hypertension in the upper part of the body was relieved completely.

Gross considered that "the optimal ages for performance of this operation lie between 6 and 20 years." Beyond the age of 25 years arteriosclerosis "makes the aorta a poor vessel for manipulation and suture." It is obvious that the early identification of coarctation of the aorta offers the patient the best chance for surgical treatment, and hence for survival.

Congenital Pulmonic Stenosis.—In May 1945, Blalock and Taussig,²³ in an epochal report, described the first successful operation for the relief of pulmonary

stenosis. They stated that the operation was indicated in cases of congenital cardiac lesions producing cyanosis when there was clinical and roentgenographic evidence of an inadequate flow of blood through the lungs. The evidence for this rests on "the absence of visible pulsations in the lung fields as observed under the fluoroscope and roentgenographic evidence that the pulmonary artery is small in size."²³ When a patient is of sufficient age so that catheterization of the heart by the venous route is feasible, this procedure may yield information which not only confirms the diagnosis, but also is a means of determining the volume of the pulmonary blood flow. In any event, if the diagnosis is doubtful in the case of a child who has decided cyanosis and if the prognosis for the patient is considered hopeless, Blalock and Taussig have considered that exploration is justified. When the pulmonary artery is exposed, the pressure in the artery can be measured by a water manometer attached to a needle which is inserted into the pulmonary artery. These observers considered operation inadvisable if the pressure in the pulmonary artery is more than 300 mm. of water.

Blalock and Taussig have reported that the operation is beneficial in (1) tetralogy of Fallot, (2) pulmonary atresia with or without dextroposition of the aorta and with or without defective development of the right ventricle, (3) truncus arteriosus with bronchial arteries and (4) a single ventricle with a rudimentary outlet chamber with which the pulmonary artery is diminutive in size.

Blalock²⁴ has reported operation on 110 patients for congenital pulmonic stenosis with an over-all mortality rate of 23 per cent. In some of these cases the operation consisted of exploration and anastomosis was not performed.

The operation results in a decrease of cyanosis, and clubbing of the fingers and toes diminishes after a period. The tolerance of the children to exercise is increased greatly after operation, and some then can engage in fairly strenuous exercise.

ABSTRACT OF DISCUSSION

TREATMENT OF HYPERTENSION

QUESTION: Is the surgical treatment of hypertension the most satisfactory way of treating this disease?

ANSWER: Not necessarily. The selection of the method of treating a patient with hypertension must rest on the careful analysis of the individual case. This study must include an attempt to discover the cause of hypertension. If coarctation of the aorta is discovered, surgical treatment of that condition is in order. If a unilateral functionless kidney is found, its removal may relieve the hypertension. If the hypertension is found to be associated with chronic nephritis, sympathectomy is unwarranted. Sympathectomy for hypertension beyond the age of 55 years is of limited or questionable value. Hypertension in young patients should be followed for some time to determine whether it is periodic in occurrence or shows a tendency to be progressive in its severity. Sympathectomy is probably indicated in the latter case but is of doubtful value in the former. The indications for sympathectomy are clearest in patients less than 50 years of age who have severe hypertension and in whom cerebral vascular accidents have not occurred, who have not had heart failure in association with pronounced cardiac hypertrophy and in whom serious renal damage has not occurred. An additional indication for operation in these cases is the occurrence of severe headaches.

GLYCOSIDES OF DIGITALIS

QUESTION: Are the purified glycosides of digitalis more useful than the powdered leaf in the treatment of heart disease?

ANSWER: One of the purified glycosides of digitalis, digitoxin, has two chief advantages. The first advantage is that a full digitalizing dose of this preparation may be given by mouth at one time with minimal prospects of producing nausea and vomiting, and the second is that by virtue of the fact that digitoxin is absorbed 100 per cent in the gastrointestinal tract, it is easier to predict the amount of the drug that must be given by mouth to produce a full effect of digitalis. However, it must be recognized that there is considerable individual variation in the amount of the drug required to produce the desired effect. The purified glycoside lanatoside C has the disadvantage that only about a tenth of the orally administered dose is absorbed in the gastrointestinal tract. Nausea and vomiting are somewhat less commonly observed in patients adequately treated with purified glycosides of digitalis than when a similar effect of digitalis is obtained by the use of a preparation of the powdered leaf.

LOW SODIUM DIET

QUESTION (Dr. Maurice D. Krauss, Brooklyn): Is there any value in a low sodium diet in compensated valvular disease?

ANSWER: A low sodium diet is indicated in a patient with compensated valvular disease of the heart who has suffered from previous cardiac decompensation. If the patient has had no such episode of cardiac decompensation, one is not warranted in subjecting him to the inconvenience of a low sodium diet.

CORONARY THROMBOSIS

QUESTION (Dr. O. P. J. Falk, St. Louis): Do you feel that heparin should be added to "dicumarol" therapy in coronary thrombosis?

ANSWER: No. If a dose of 300 mg. of "dicumarol" is given immediately after acute coronary thrombosis, an adequate effect on the coagulability of the blood will be obtained in forty-eight to seventy-two hours. Thromboembolic episodes are extremely unlikely to occur in the first two or three days after acute coronary occlusion.

DOSAGE OF HEPARIN AND "DICUMAROL"

QUESTION (Dr. H. S. Connamacher, Newark, N. J.): What doses and what frequency do you use with heparin and "dicumarol"?

ANSWER: Heparin is given intravenously by two methods. 1. It may be given by a continuous drip method starting at 25 drops per minute and varying the rate of injection so that the coagulation time of venous blood is kept between fifteen and twenty-five minutes. The intravenous solution is made by adding 100 to 200 mg. of heparin to 1,000 cc. of a diluent, either a 0.9 per cent solution of sodium chloride or a 5 per cent solution of dextrose. 2. A concentrated solution of heparin of either 5 cc. (50 mg. of heparin) given every four hours or 10 cc. (100 mg. of heparin) given every six hours may be administered intravenously. With this latter method the coagulation time is not followed, and despite the fact that the coagulation time returns to normal between injections, the method seems to be effective. Heparin may be given subcutaneously or intravenously in the Pitkin menstrium every two or three days (Loewe, L., and Rosenblatt, P.: A New Practical Method for Subcutaneous Administration of Heparin; Preliminary Report. *Am. J. M. Sc.* 208:54-63 [July] 1944. Barker employs the following dosage schedule for "dicumarol" at the Mayo Clinic: The entire amount for one day is given in a single dose. The first dose is 300 mg. On each subsequent day when the prothrombin is greater than 20 per cent of normal prothrombin, 200 mg. of "dicumarol" is given. On days when the prothrombin is less than 20 per cent of normal, no "dicumarol" is given. If the prothrombin drops below 10 per cent of normal during the first few days, 20 to 30 mg. of menadione bisulfite is given intravenously, and thereafter only 100 mg. of "dicumarol" is given to that patient on those days on which the prothrombin is greater than 20 per cent of normal. With this schedule, prothrombin deficiency has been maintained for as long as six months without untoward or toxic effect on

24. Blalock, A.: The Surgical Treatment of Congenital Pulmonic Stenosis, *Ann. Surg.* 124: 879-887 (Nov.) 1946.

the patient and with return of prothrombin to normal within a few days after administration of "dicumarol" finally was discontinued.

WILSON'S UNIPOLAR LEAD

QUESTION (Dr. Peter Pileggi, Bridgeport, Conn.): Please say a few words on the value of Wilson's unipolar lead, especially in the diagnosis of cases of acute coronary thrombosis when other leads are negative?

ANSWER: This question does not relate to treatment and cannot be discussed in the limited scope afforded for answers to these questions.

TREATMENT OF RHEUMATIC HEART DISEASE

QUESTION: Are there effective methods of treating and preventing rheumatic heart disease?

ANSWER: Yes, with certain limitations. 1. In treatment of an acute attack of rheumatic fever salicylates should be administered in large doses by mouth to lower the fever, control pain and reduce the sedimentation rate, but this does not constitute a cure of the disease. The patient should be kept at rest in bed until evidences of activity of the rheumatic fever process have disappeared. Beyond this, activity may be gradually resumed, but it is important to isolate the patient for several months from contacts which might allow him to acquire an acute infection of the respiratory tract. 2. In a child that has had one or more attacks of rheumatic fever, the daily administration of sulfadiazine, except possibly during the summer months, seems definitely to diminish the likelihood of his having a recurrence of rheumatic fever. Improvement of the environment, including adequate housing, clothing and food, and the avoidance of excessive fatigue in the succeeding preadult years add greatly to the protection that can be afforded against recurrent attacks of rheumatic fever. Children who have had rheumatic fever are better protected from recurrences by residence in a warm climate. Their hazard is increased by residence in children's homes or in large families where the chance of acquiring acute infections of the respiratory tract is greatly increased.

USE OF HEPARIN

QUESTION: Has the use of heparin in subacute bacterial endocarditis any value?

ANSWER: It is the consensus that it has no use in this condition. In my personal experience, the use of heparin in the treatment of subacute bacterial endocarditis has led to serious complications.

USE OF THIOURACIL

QUESTION (Dr. Benjamin Miller, Baltimore): Please discuss the use of isopropyl thiouracil in heart disease; that is, cases that are not directly thyrotoxic in etiology.

ANSWER: The usefulness of isopropyl thiouracil in the treatment of heart disease is predicated on its function of reducing the basal metabolic rate. The care that must be exercised to be certain that neutropenia does not result, and the untoward general effects produced if very low basal rates are reached, greatly reduce its usefulness for practical purposes. The result of its use in the treatment of heart disease to date is not sufficiently demonstrated to warrant its general use for this purpose.

MERCURIAL DIURETICS

QUESTION (Dr. H. W. Stevens, Middleboro, Mass.): What benefits can be effected by mercurial diuretics that are not possible by careful control of sodium intake and other control of diet and activity?

ANSWER: Most cases of heart failure are controlled by a low sodium intake, the judicious use of digitalis preparations and control of the patient's activity. However, practical experience has shown that in spite of these measures, edema in some cases can be controlled only by the periodic administration of mercurial diuretics.

SODIUM PENICILLIN

QUESTION (Dr. Edward R. Barber, Lancaster, S. C.): Is the sodium in sodium penicillin present in sufficient amounts to cause harm in a patient with congestive heart failure and to warrant the use of another type of penicillin?

ANSWER: The amount of sodium in sodium penicillin is so small as scarcely to be a factor in the production of edema when administered to a patient with congestive heart failure. If there were any question, the penicillin could be given as calcium penicillin, which is the form in which I administer most of the penicillin given under my supervision.

USE OF POTASSIUM CHLORIDE

QUESTION (Dr. Glen Pincock, Washington, D. C.): In cardiac decompensation is the substitution of potassium chloride as "salt" in place of sodium chloride advisable?

ANSWER: In cardiac decompensation potassium chloride may be substituted as "salt" for sodium chloride if the patient finds it renders his food more palatable.

USE OF THIOCYANATES

QUESTION: How safe are thiocyanates for use by general practitioners?

ANSWER: Thiocyanates can be used most safely only if their dosage is controlled by periodic determinations of the levels of the cyanates in the blood. If a patient has been followed over a sufficient period of time with determination of levels of the cyanates in the blood and if a safe dosage level has been established, he usually may continue that dose under the direction of his home physician. Even then, the patient should be instructed to report to his physician if a cutaneous rash or gastrointestinal symptoms appear. Most patients will tolerate a dose of 6 grains (0.4 Gm.) of potassium thiocyanate daily without the risk of untoward symptoms, but often that dose does not produce blood levels sufficiently high to be very useful in the treatment of hypertension. Physicians should also be aware that the thiocyanates may produce myxedema and should be alert for signs of its development.

ANTICOAGULANTS

QUESTION (Dr. Paul A. Sica, Pittsburgh: Are you routinely using anticoagulants in all your cases of acute myocardial infarction?

ANSWER: Yes.

QUESTION (Dr. E. P. Bray, Richmond, Va.): In acute myocardial infarction when and how would one start anticoagulant therapy?

ANSWER: See answers to the fourth and fifth questions.

HYPERTENSIVE ENCEPHALOPATHY

QUESTION: Please discuss the use of hypertonic sugar solution and magnesium sulfate in hypertensive encephalopathy. Please discuss the changes in blood lipids which are responsible for the appearance of lipemia retinalis and xanthoma diabeticorum.

ANSWER: This is too much to attempt to answer in the scope allowed for answers to such questions.

SYPHILITIC ANEURYSM

QUESTION (Dr. R. Weyher, Detroit): Is penicillin therapy justified in an early thoracic syphilitic aneurysm with mild cardiac failure?

ANSWER: In general the answer is no. There are reports of deaths due to Herxheimer reactions in patients treated with large doses of penicillin for syphilis of the aorta. If penicillin is used in such a situation, great care should be taken and small doses of penicillin employed over a long period of time. One could not expect improvement in the aneurysm. The cardiac failure would have to be treated by the usual measures employed in treating such a condition if it were of nonsyphilitic origin.

IDIOSYNCRASY TO QUINIDINE

QUESTION (Dr. A. Alexander Bernstein, Scranton, Pa.): When patients show an idiosyncrasy to quinidine, in auricular fibrillation, what do you use?

ANSWER: I have little to offer anybody who is permanently sensitive to quinidine, but I would remind the man who asked this question that by stopping quinidine it may be possible to resume its use later and have the patient take it successfully.

RECENT ADVANCES IN TREATMENT
OF CANCER

CORNELIUS P. RHOADS, M.D.

Director, Memorial Hospital and the Sloan-Kettering Institute
for Cancer Research
New York

The pattern of recent advances in the treatment of cancer differs somewhat from that of the past. It represents, perhaps, an indication of a new trend, long foreseen, toward more radical surgery on the one hand and toward new biochemical approaches on the other. This denotes a strengthening of the position of surgery as a curative agent, coincidentally with an intensified search for new means of palliation and control.

The procedure devised by Mohs,¹ entitled "Chemosurgical Treatment of Cancer," has recently been the subject of a review of five year end results of its application to neoplasms of the ear. The method is beyond question an interesting one and deserving of careful consideration. Of 19 patients with squamous cell carcinoma treated, 9 are well after five years. It is unfortunate that no figure is given for the five year salvage in cases of disease recurrent after efforts at therapy by other means. It is stated that 53 per cent of patients with recurrent disease were successfully treated, but the duration of the success is not specified. The same objection can be raised to the figures reported for the treatment of basal cell carcinoma. Here 81 per cent of five year cures are reported, but no duration for the 76 per cent cures of recurrent disease. The cure rates for skin cancer adequately treated by conventional surgical or radiologic means are, of course, exceedingly high also.

CANCER OF THE UPPER RESPIRATORY TRACT

Nowhere is the drift toward more radical surgery seen more clearly than in the treatment of neoplasms of the oral cavity and the upper respiratory tract. Unfortunately cancer of the mouth and associated structures varies greatly in prognosis according to site. As a result statistical proof of the value of the extensive surgery now practiced is not yet at hand. Sufficient evidence is available, however, to suggest that much oral disease, now frequently classified as suitable for only palliative care, is actually susceptible of cure if bold measures are undertaken by competent operators.

The question of the most effective treatment of laryngeal cancer is still debated in some circles. A review of the results of radiation therapy of cancer of the larynx has recently been published by Lenz.² Of 110 patients studied, 30 are reported to be free of disease for periods of over five years. He recommends roentgen therapy for all cancers of the vocal cord except when disease has extended subglottally or into the arytenoid cartilage. This conclusion is based on 8 survivals of 10 patients treated. The report of Cutler³ suggests that a five year cure rate of 60 per cent, as high

as the one seen after surgery, can be obtained by the use of roentgen rays alone in patients who would normally have been subjected to laryngectomy. The experience on which this opinion is based, however, seems to be limited to a total of 10 patients, as far as can be concluded from the published data. In a more recent report⁴ 18 five year cures, or 42 per cent of 47 patients treated, are reported. There can be no doubt whatever that certain patients with laryngeal disease are and should be cured by roentgen irradiation. The loss of voice and the hazard associated with the surgical removal of the larynx have been in the past serious deterrents to operative intervention in general. Modern technics for the development of the esophageal voice and the ability of Martin and his associates⁵ to perform one hundred and ninety-three total laryngectomies for cancer with only 3 operative fatalities (1½ per cent), including a series of 102 consecutive cases without any postoperative death, and a cure rate of about 60 per cent in 44 cases in which operation had been performed more than five years previously, have altered the situation. It is hard to conceive of diagnostic criteria and acumen so accurate as to make possible a uniformly reliable decision as to whether a given example of laryngeal cancer is capable of being cured by roentgen irradiation. On the basis of the facts now available, surgery undoubtedly sacrifices some larynxes which could have been saved by radiation therapy. Surgical intervention probably saves 50 per cent more lives, however, a significant number, and many prefer their lives to their larynxes.

CANCER OF THE BREAST

The treatment of cancer of the breast remains surgical as far as cure is concerned. The procedures employed are so standardized as to be hardly worth comment. One set of facts deserves attention, however. In one clinic amputating, without skin graft, more than five hundred breasts annually for cancer, the five year cure rate for all patients found to have involvement of axillary lymph nodes is 46 per cent, the postoperative mortality 0.2 per cent and the incidence of local skin recurrence not over 19 per cent. These figures indicate that the exceedingly radical procedure frequently advocated for all amputations of the breast for cancer is not always required. They fail to support the feeling of some that no true, wholly autonomous cancer is ever cured.

The palliative care of patients with metastatic disease of the breast provides an interesting and important development. Here hormone therapy clearly is irregularly and transiently effective. The early reports of Fels⁶ and of Loeser⁷ have been supported by the observations published recently by Adair and Herrmann.⁸ The administration of testosterone propionate in doses adequate to cause masculinization brings about irregularly demonstrable calcification of previously decalcified areas of mammary cancer metastatic to bone. This

seems to occur in over 15 per cent of the patients treated and to be of variable duration. Subjective improvement, indicated by gain in weight and relief of pain, can be striking. Certain patients are encountered, however, as first described by Farrow and Woodard,⁹ whose blood calcium levels are somewhat elevated before treatment is begun, in whom profound and possibly dangerous hypercalcemia follows administration of testosterone. In these persons pain may be relieved coincidentally with a rapid and extensive spread of the metastatic neoplasm.

The use of estrogenically active substances, particularly diethylstilbestrol, in the treatment of metastatic cancer of the breast was initially described in England.¹⁰ It has been explored further in this country, particularly by Nathanson.¹¹ The beneficial effects are seen principally when soft tissues are involved. This contrasts sharply with the results of testosterone therapy, which are almost entirely seen in metastases to bone. The incidence of improvement of soft tissue lesions is about the same (15 per cent) as the improvement of osseous lesions after testosterone therapy. Similar complications may occur, and improvement is equally transient.

The review by Halberstaedter¹² of the effects of oophorectomy on patients with metastatic disease of the breast deserves to be consulted. It is an odd fact that this procedure, so often reestablished as useful, continues to need defense.

ABDOMINAL CANCER

The radical surgery of abdominal cancer has been the subject of a major contribution by Brunschwig.¹³ This surgeon reports the results of one hundred very extensive operative procedures. The patients had cancer which had extended locally to invade organs other than the one primarily involved. Fifty per cent of the patients were early fatalities or received no palliative benefit; 37 per cent returned to their usual occupations only for periods of from weeks to months, and 13 per cent have been free of disease for two to ten years. The policy adopted by Brunschwig of attempting, at least, the removal of locally invasive disease, inoperable by ordinary standards, has been criticized on the score of practically every criterion of culpability. The logic in these criticisms is hard to ascertain. The cure rate obtained, 13 per cent, is as high as that for all patients treated for rectal cancer in the state of Connecticut,¹⁴ higher than the cure rates for neoplastic disease of lung, stomach, bone and bladder. There can, indeed, be no logical argument against the use of heroic measures to save life. The 13 patients salvaged of the 100 treated certainly represent pure gain. They are willing, I feel sure, to pay tribute to the determination, vision and technical ability of the surgeon.

CANCER OF THE THYROID GLAND

The treatment of cancer of the thyroid gland by radioactive iodine is a possibility which has been hailed with great enthusiasm by those who deal with the manufacture of atomic bombs, because of the humane application of the by-products. The primary observations of Hamilton¹⁵ and of Frantz¹⁶ that radioactive iodine was stored in several of a large number of metastatic nodules of a primary thyroid adenocarcinoma has led to further studies. Seidlin, Marinelli and Oshry¹⁷ have reported on the treatment with radioactive iodine of an extraordinary patient. This person had hyperthyroidism from functioning metastases of thyroid adenocarcinoma. The normal thyroid had been wholly removed and there was no uptake of radioactive iodine by the tissue of the neck. Thyroxin iodine was demonstrated in the metastases and thiouracil produced a complete remission of the hyperthyroidism. This recurred when the drug was withdrawn. Therapy with I¹³¹ has controlled not only the hyperthyroidism but also the cancer for over four years.

Particularly pertinent to the problem of treatment of thyroid cancer is the study of Marinelli, Foote, Hill and Hocker.¹⁸ An effort was made to correlate the pick-up of radioactive iodine with the histologic type of thyroid neoplasms. Detectable deposition of radioactive iodine was found in only about 15 per cent of thyroid cancers. As might have been expected, deposition of iodine was greatest in metastasizing struma and least in the more anaplastic types of solid carcinoma. It is to be hoped that some procedure can be devised for increasing the uptake of iodine by the less differentiated tumors of the thyroid. If this is not done, therapeutic successes are likely to be few.

CANCER OF THE BLADDER

The recent communications of Jewett¹⁹ and of Marshall²⁰ concerning cancer of the bladder merit particular attention. Jewett in a careful study proved that in about 25 per cent of patients whose cancer of the bladder has infiltrated the muscular wall there is no extension into adjacent structures. Marshall reported a post-operative mortality for ureteral transplantation and total cystectomy of approximately 10 per cent and a five year cure rate for cancer of the bladder treated by radiation of 6 per cent. From these facts it appears likely that the more extensive use of total cystectomy in the future should result in a significant improvement in rate of cure, since the disease of many patients in the group reported by Jewett should be susceptible to control by surgery.

THE NITROGEN MUSTARDS

The most noteworthy advance in the treatment of neoplastic disease during 1946 has been in the use of the nitrogen mustards. From the days of World

War I it has been known that mustard gas injures hemopoietic tissue. Studies of chemical warfare agents jointly by Army and Office of Scientific Research and Development contractors confirmed the fact and extended knowledge of the details. Gilman,²¹ while a contractor working under military secrecy, was the first to apply the mass of new pharmacologic knowledge to the treatment of a patient with lymphosarcoma. Later Jacobson,²² also on a war research contract, extended the observation and found particularly good effects in Hodgkin's disease. In 1914 the most promising nitrogen mustard, commonly termed HN₂, was made available by the Office of Scientific Research and Development to the National Research Council for distribution to three representative institutions for the treatment of patients. A summary of the results obtained appeared in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.²³ During the past year it has been available on request to institutions qualified under the rulings of the Food and Drug Administration. Over five thousand treatment units have been distributed to one hundred and twenty-six institutions and over one thousand one hundred clinical reports have been received. Of these about 60 per cent provide data suitable for analysis. The study has been supervised by a representative of the Committee on Growth of the National Research Council, Dr. David Karnofsky. The results can be summarized as follows, though exceedingly incomplete:

1. Hodgkin's disease. About 70 per cent of the patients with Hodgkin's disease show objective improvement and about 90 per cent subjective response. Remissions last about one month in most instances, but may rarely endure as long as six months. Responses can be obtained to subsequent courses of treatment.

2. Myeloid leukemia. Full remissions can be induced in early and moderately advanced stages of myeloid leukemia. These remissions are of the type which results from roentgen irradiation but tend to be of shorter duration.

3. Lymphosarcoma and lymphatic leukemia. Improvement in cases of lymphosarcoma and lymphatic leukemia can be obtained but tends to be of limited degree and transient. Severe toxic reactions of the hemopoietic system are common and the use of the drug is not recommended.

4. Acute leukemia seems not to be influenced favorably in its course.

5. Cancer of the gastrointestinal tract, oral cavity, breast and genitourinary systems is not inhibited.

6. Cancer of the lung can be caused to regress temporarily in about 50 per cent of the instances. The effects are transient and incomplete.

7. Melanoma and tumors of the central nervous system may possibly respond to some extent. More information is needed.

The advances described and recently reported are not events of 1946 alone. They represent the accumulated force of the experience of a considerable period. They,

coupled with new mechanisms for early diagnosis and mass examination, have already lessened the age-adjusted death rate from cancer. The intense public resolution to be rid of the threat of this grave disorder bids fair to provide rapid progress in the future.

ABSTRACT OF DISCUSSION

HODGKIN'S DISEASE

QUESTION (Dr. Robert D. Redston, New York): Has it been observed that cases of Hodgkin's disease progress more rapidly toward termination after treatment with nitrogen mustard and a remission of variable duration?

ANSWER: From the survey which has been made under the auspices of the National Research Council there is no reason to believe that Hodgkin's disease progresses more rapidly toward termination after nitrogen mustard therapy, followed by remission.

CANCER OF PROSTATE

QUESTION: What is the most effective chemical treatment of carcinoma of the prostate?

ANSWER: Adequate data are not at hand to answer this question. There is no doubt whatever that diethylstilbestrol or its derivatives have a distinct though temporary clinical effect. It is commonly supposed that the effect is due to the estrogenic potency of the chemical used.

ESTROGENS AND CANCER OF BREAST

QUESTION: Is there danger in producing cancer of the breast with the use of estrogenic substances?

ANSWER: I know of no danger of producing cancer of the breast by the administration of estrogenic substances. A very few reports are available of patients in whom cancer of the breast developed after intensive therapy with estrogens. In view of the extensive use of estrogens in treatment, and the comparatively common nature of cancer of the breast, few workers in the field believe there is any connection between the administration of hormone and neoplastic change. The doses of estrogenic hormone used to induce mammary cancer in susceptible strains of animals are far larger than those used in human therapy.

TREATMENT OF CANCER

QUESTION: Are there any new chemicals effective in the treatment of cancer?

ANSWER: I know of no new chemicals which have been proved to be effective in the treatment of cancer in man.

GASTRIC CANCER

QUESTION (Dr. F. G. Kojis, New York): What is the effect of estrogens on gastric carcinoma?

ANSWER: No effect has been shown to be exerted by estrogens on the course of gastric carcinoma.

USE OF TESTOSTERONE IN CANCER OF THE BREAST

QUESTION (Dr. Clarence Bernstein, Orlando, Fla.): What is the average dosage of testosterone propionate in the treatment of metastases of breast cancer (in a patient of average weight), with pleural effusion? Is there any real danger of overdosage and what would be the clinical or physiologic effects?

ANSWER: The usual dose of testosterone propionate in the treatment of osseous metastasis from cancer of the breast is 25 mg. daily by intramuscular injections. The development of marked symptoms of masculinization is an indication for decreasing the dose. The compound should be used to its biologic effect. There is real danger of overdosage in certain rare patients; in these persons severe hypercalcemia may occur and be marked by all the usual symptoms of this disorder. Patients receiving testosterone propionate therapy should be checked at regular intervals for blood calcium levels.

23. Rhoads, C. P.: *Nitrogen Mustards in the Treatment of Neoplastic Disease*, J. A. M. A. 131: 656 (Jne 22) 1946.

SURGERY FOR ABDOMINAL CANCER

QUESTION (Dr. Wilfred Dorfman, Brooklyn): Please discuss in further detail the type of surgery used for abdominal cancer. What type of case can be helped?

ANSWER: For an answer to this question the recently published book by Dr. Alexander Brunschwig, entitled "Radical Surgery in Advanced Abdominal Cancer" (1947, Chicago, University of Chicago Press) should be consulted. Most of the patients who were helped by Dr. Brunschwig were those who had considerable local extension of the primary cancer without blood-borne metastases.

TREATMENT OF MULTIPLE MYELOMA

QUESTION (Dr. Nathan Schechter, Ottawa, Ontario, Canada): What is the best treatment of multiple myeloma?

ANSWER: The course of multiple myeloma untreated is so variable that firm conclusions as to the best method of therapy are difficult to formulate. The use of such compounds as "stilbamidine" (4,4'-diamidinostilbene) is still in the experimental phase.

HEMATOLOGY

RUSSELL L. HADEN, M.D.
Cleveland

Important advances in hematology during the past year concern the use of folic acid in anemia and further trial of radioactive isotopes and other new chemicals in the treatment of leukemia and polycythemia. The therapeutic application of folic acid has reemphasized also the need for an accurate laboratory study and classification of the anemias before treatment is begun, since this drug is indicated only with macrocytosis.

FOLIC ACID

Synthetic folic acid (pteroylglutamic acid) is now available in unlimited quantities. It is of value only in a macrocytic anemia with a megaloblastic bone marrow. Important examples of such an anemia are (1) idiopathic pernicious anemia, when there is deficient formation of a specific erythrocyte-maturing factor (EMF); (2) macrocytic nutritional anemia in children due to a defect in supply or absorption, the macrocytic anemia of pregnancy due to increased need and the macrocytic anemia of adults dependent on a defective absorption of the specific substances resulting from a small bowel lesion such as obstruction or multiple anastomoses; (3) sprue, and (4) pellagra. There is no evidence that folic acid helps in a hypochromic anemia due to a deficiency of iron or in the normocytic anemias due to other causes such as infection, malignancy or increased hemolysis. Folic acid may well be the specific substance needed by the developing red cell to complete its development in the marrow before release into the blood stream. Growing red cells lacking this substance are larger than normal, so that macrocytosis is an indication of a need for the drug. The routine use of folic acid in every type of anemia is to be deplored.

Folic acid when given in sufficient amounts in a properly diagnosed and selected case will relieve the anemia and macrocytosis with a return of the blood to

normal. The glossitis, diarrhea, weakness and anorexia often seen in such patients may be relieved entirely also. The drug is quickly absorbed and is effective by mouth. It seems the drug of choice in the treatment of the macrocytic anemia of sprue, pellagra, pregnancy and other nutritional disturbances. Probably the nutritional defect is the same in each instance; namely, a loss of supply or absorption of a specific substance which may be folic acid. All such conditions are responsive to the administration of a potent liver extract, so that folic acid is replacing an already satisfactory treatment largely because it may be given in any amount and by mouth rather than by hypodermic injection.

Should folic acid replace liver extract in the treatment of pernicious anemia? This is a complicated disease involving (1) the hemopoietic system, (2) the gastrointestinal tract and (3) the peripheral and central nervous systems. The disease is a primary defect in the gastric mucosa resulting in a defective formation of the specific erythrocyte-maturing factor (EMF) also deficient in the macrocytic anemias already discussed. The exact cause of the lesion in the nervous system has never been clear, although it seems evident that there is something lacking which is necessary for the normal nutrition of nerve tissue. It has not been known whether this is the same substance needed to form red cells, although it has been evident to all hematologists that the symptoms and signs referable to the nervous system were benefited and often relieved by adequate liver therapy. Perhaps experiences with folic acid have cleared up this question.

The macrocytic type of pernicious anemia is cured completely by the use of folic acid, probably because a specific deficiency is supplied. There is no evidence, however, that folic acid has any influence on the neurologic lesion of pernicious anemia. On the contrary, experience suggests that the lesions in nerve and spinal cord may develop rapidly even with folic acid therapy adequate to relieve the anemia. The neurologic lesion is the most disabling and serious phase of pernicious anemia. Once well developed it is difficult to help by treatment, so that any treatment which does not influence the neurologic lesion should not be used.

Folic acid should not be used for the routine treatment of pernicious anemia. Liver extract remains the treatment of choice for this disease. Properly carried out it is almost a perfect treatment for pernicious anemia. There is no evidence that the addition of folic acid to liver extract enhances its value in pernicious anemia. It only adds to the cost. In patients allergic to liver extract the best substitute is folic acid. Such a condition is rare, however, and can usually be handled by changing the brand of the liver extract used. In our large series colleagues and I have encountered no patient whom we could not treat with some liver extract.

Folic acid, while not satisfactory for the treatment of pernicious anemia, has helped in clarifying the mode of action of liver extract in the macrocytic anemias. Liver extract has been thought of in the past as actually supplying some missing substance necessary for the normal growth of red cells and for the nutrition of nerve tissue. Liver extract does contain a small amount of folic acid but not enough to explain its beneficial effect on blood formation. Recent work indicates that the liver extract activates substances needed by erythrocytes and nerve tissue through its general action on cellular

From the Cleveland Clinic.
Read in a Panel Discussion on Recent Advances in Treatment before the joint meeting of the Section on Internal Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

metabolism. It has been suggested that so far as the red cells are concerned the action of liver extract is to free folic acid (pteroylglutamic acid) from its inactive conjugated form, in which it naturally occurs in food-stuffs. Thus released, it enters into the growth of red cells. It probably similarly makes available some substance needed by nerve tissue, so far undetermined, which is not folic acid. Further study may identify such a substance. This point of view on the action of liver extract suggests that pernicious anemia is a complex type of cellular enzyme disturbance which the extract restores to normal with release of specific substances needed for normal red cell growth (pteroylglutamic acid) and for the normal nutrition of nerve tissue (a substance so far not identified).

RADIOACTIVE ISOTOPES IN TREATMENT OF LEUKEMIA AND POLYCYTHEMIA

Roentgen irradiation has long been the best available method for treating leukemia. It only slightly prolongs life, however, although the patient is made more comfortable by such therapy. Radioactive isotopes in recent years have been tried to replace roentgen therapy. Radioactive phosphorus, P^{32} , has been most widely used. The effect of this isotope is identical with that of other forms of irradiation. The only value claimed for it is the absence of radiation sickness. This is of no significance, however, in the hands of many radiologists who use small doses of roentgen rays. It has been suggested that no radioactive isotope should be used for treatment if the half-life is more than ten days because of possible unfavorable late effects from the long-continued irradiation. The half-life of radioactive phosphorus is 14.3 days. The occurrence of acute leukemia in patients with polycythemia treated with radioactive phosphorus raises the question of such possible ill effects. Even with the availability of P^{32} from Oak Ridge the drug remains expensive, requires special facilities for handling and is not generally available for clinical use. It has not been widely used but has been employed largely in research centers. More recently radioactive gold and manganese have been employed in the treatment of leukemia with much the same results as with P^{32} .

The use of radioactive isotopes has not greatly changed the outlook of the patient with leukemia. All patients eventually die from the disease. The average length of life in leukemia without any treatment is three years. With roentgen therapy the average is 3.5 years, and the patient is more comfortable. With radioactive phosphorus treatment the average is 3.6 years. The clinician should not feel that his patient is being deprived of an indispensable treatment if radioactive phosphorus is not available, provided roentgen therapy is used.

Other chemicals which have been found to have an effect similar to roentgen rays have been tried for leukemia. The nitrogen mustards have such an effect but are more valuable in Hodgkin's disease than in leukemia; even here, however, the effect is not remarkable. Urethane (ethyl carbamate) has been tried recently. This drug and nitrogen mustard were first used because they were found to cause leukopenia. When administered it has an effect much like roentgen irradiation but may cause nausea and vomiting. It is now being employed experimentally in many clinics.

There is no evidence that it has any curative effect, but it may prove to be a valuable treatment for leukemia since it has few toxic effects, is readily available and is cheap. It may prove to be as valuable as roentgen irradiation in many cases. It is more effective in the myeloid than the lymphoid types of the disease.

In polycythemia the radioactive isotopes are probably the treatment of choice if readily available. The results with repeated venesections in this disease are most satisfactory, however, and so far the best alternative treatment. The effects with P^{32} are only temporary. There is no evidence that a patient lives longer with such treatment than with venesection. Only time can determine the place of such drugs in the treatment of polycythemia.

ABSTRACT OF DISCUSSION

PERNICIOUS ANEMIA WITH CORD SYMPTOMS

QUESTION (Dr. V. E. Lascara, Raleigh, N. C.): Given a case of pernicious anemia with spinal cord symptoms, what is the best therapeutic procedure?

ANSWER: A patient suffering from pernicious anemia with symptoms referable to the spinal cord requires more intensive treatment than with an anemia only. At the beginning 15 units of liver extract is given daily for two weeks. After this initial treatment 15 units is given twice weekly for three months. An injection of 15 units is then given weekly indefinitely, or at least until it is shown that no further improvement in the cord lesion is possible. This improvement may be slow, however, and may continue for a long period. A full diet including abundant meat, eggs, fruit and vegetables without an excess of carbohydrate should be insisted on. It is a question whether added vitamin B helps the cord lesion. It is a good procedure, however, to give a teaspoonful of dried brewer's yeast powder three times a day.

TREATMENT OF POLYCYTHEMIA

QUESTION (Dr. R. H. Clark, Hattiesburg, Miss.): Discuss further treatment of polycythemia.

ANSWER: Idiopathic polycythemia vera responds well to the administration by mouth or intravenously of radioactive phosphorus (P^{32}). This is available, however, only in larger centers. The final results of the treatment of polycythemia with this radioactive isotope will depend on the clinical course observed as the result of such treatment. Venesection is a satisfactory method of treating idiopathic polycythemia vera. The red cell mass (hematocrit reading times blood volume) is greatly increased in this disease and should if possible be determined in gaging treatment. A large amount of blood must be removed, depending on the level of the red cell mass. This is variable. It is safe to do venesections until the hematocrit reading shows 45 cc. of red cells per hundred cubic centimeters of blood.

CEREBRAL HEMORRHAGE

QUESTION (Dr. Sixto Y. Orosa, Bacolod, Philippines): Is it logical to use "dicumarol" or heparin in cerebral hemorrhage? Have cases been reported? Has folic acid been tried in leukemia? If so, with what results?

ANSWER: There is no reason to use heparin or "dicumarol" in cerebral hemorrhage. Folic acid has been tried in leukemia without success.

LEUKEMIA

QUESTION (Dr. Nathan Blumberg, Philadelphia): What is the value of urethane and nitrogen mustard in the leukemias and what is the usual life span after these drugs have been given to a patient with leukemia?

ANSWER: Both urethane and nitrogen mustard may help leukemia. These should be tried early in the course of the

disease or when the patient no longer responds to irradiation. The life span of patients with leukemia is so variable it is not possible to estimate this after the use of such drugs.

PERNICIOUS ANEMIA

QUESTION (Dr. P. Lancione, Bellaire, Ohio): Just how would you treat a patient with pernicious anemia?

ANSWER: A patient with pernicious anemia should be treated intensively at the beginning and adequately throughout his life. An excellent plan is as follows: 15 units of liver extract daily for the first two weeks, twice weekly for three months, weekly for three months, twice monthly for six months and monthly for the life of the patient.

CRUDE LIVER AND LIVER EXTRACT

QUESTION (Dr. Leslie S. Harrison, Flushing, N. Y.): Is crude liver better than liver extract for treatment of pernicious anemia?

ANSWER: It is doubtful whether crude liver extract is better than a refined preparation for the treatment of pernicious anemia. Some workers have thought that the cord lesions of pernicious anemia might be helped more by the crude extracts.

FOLIC ACID AND NEUROLOGIC RELAPSES

QUESTION (Dr. Morton S. Berk, Boston): What is the evidence that folic acid may cause an actual increase in the incidence of neurologic relapses in pernicious anemia?

ANSWER: Numerous workers have reported the development and progress of neurologic lesions in patients having intensive folic acid therapy. At times the lesions seem to develop explosively. There is no proof, however, that the incidence is greater. All agree with Dr. Tom Spies (*Experiences with Folic Acid*, 1947, Chicago, The Year Book Publishers, Inc., p. 82), however, that "It seems evident that folic acid does not always prevent the occurrence of combined system disease nor does it reverse the degenerative process once it has begun." These observations suggest that until more is known of the mode of action of folic acid in hemopoiesis and until a factor essential to the preservation of the central and peripheral systems is found, liver extract is the safest and most effective therapeutic agent for the routine treatment of pernicious anemia.

THE BLOOD PATTERN IN MALIGNANCY

QUESTION (Dr. Arthur H. Hopkins, Philadelphia): Will you give us your opinion of the value of "The Blood Pattern in Malignancy" as demonstrated and described by Dr. Leonard Bolen?

ANSWER: I have had no experience with this procedure.

USE OF NITROGEN MUSTARDS

QUESTION: Discuss the use of nitrogen mustards in the treatment of lymphatic diseases.

ANSWER: Many lymphoblastomas respond to treatment with the nitrogen mustards. If a lesion does not respond initially to irradiation it probably will not respond to nitrogen mustard, so roentgen irradiation seems the method of choice. After a patient's lesion has become resistant to irradiation it may respond, however, to the administration of nitrogen mustard, sometimes with restoration of sensitivity to irradiation. The greatest usefulness of nitrogen mustard so far is in Hodgkin's disease, in which the palliative results may be most striking. This drug is not a cure, however, any more than irradiation is a cure.

SECONDARY ANEMIA

QUESTION: What is the most effective way of treating secondary anemia?

ANSWER: The term "secondary anemia" is an unfortunate one. Earlier it was used to designate an anemia due to a known cause as opposed to "primary anemia" of unknown origin. In this sense both pernicious anemia and chlorosis were grouped together as primary anemia. Anemias due to hemorrhage, increased hemolysis, bone marrow aplasia, and bone

marrow depression were classed as secondary. Every case of anemia should be studied carefully in the laboratory for evidence of increased hemolysis and for size and hemoglobin content of the red cell. Such data usually give a clue to the cause of the anemia. The clinical study of the patient should give other information. After determining the type and cause of anemia, treatment is simple, provided the cause can be removed or compensated for. If there is a low color index and/or volume index iron is indicated. This is best given as ferrous iron in adequate doses such as 9 to 15 grains (0.6 to 1 Gm.) daily.

FOLIC ACID

QUESTION (Dr. B. Spencer, Sterlington, La.): Does folic acid have a diuretic action?

ANSWER: No.

FOLIC ACID AND IMPULSE TRANSMISSION

QUESTION (Dr. George J. Boines, Wilmington, Del.): Has folic acid any effect on impulse transmission at the myoneural junction?

ANSWER: No.

THE EFFICACY OF FOLIC ACID

QUESTION (Dr. S. R. Blatteis, Brooklyn): What are the criteria indicating the efficacy of folic acid and is it advisable to continue the administration of folic acid at all during a remission in pernicious anemia?

ANSWER: Many workers have shown that macrocytic anemia due to a deficiency of the specific erythrocyte-maturing factor such as pernicious anemia responds dramatically to the administration of folic acid. The red cell count returns to normal and macrocytosis disappears. True pernicious anemia is due to a permanent deficiency of the specific factor, so must be treated throughout the life of the patient. Treatment should never be discontinued during a remission. Pernicious anemia is best treated with liver extract and not by folic acid alone.

FOLIC ACID IN MACROCYTIC ANEMIA

QUESTION (Dr. Paul W. Spear, Brooklyn): Is folic acid effective in the macrocytic anemias due to nutritional deficiency? Has it been tried in so-called achrestic anemia?

ANSWER: Folic acid is effective in the macrocytic anemia of sprue and the macrocytic anemia of childhood, both of which are due to a deficiency of the specific erythrocyte-maturing factor. There is much to suggest that folic acid is this specific factor. The term achrestic anemia has been used to designate a macrocytic anemia similar to pernicious anemia which does not respond to adequate liver therapy. It is doubtful whether there is a pernicious anemia which does not respond to liver. Achrestic anemia is probably not due to a deficiency of the specific erythrocyte-maturing factor and so would not be expected to respond to folic acid. A macrocytic anemia is present in liver disease, primary aplastic anemia, and in monocytic leukemia.

HYDROCHLORIC ACID NOT RECOMMENDED

QUESTION (Dr. J. P. Scias Jr., Buffalo, N. Y.): In the treatment of pernicious anemia or other anemias associated with achlorhydria, does hydrochloric acid by mouth play a part?

ANSWER: The use of hydrochloric acid does not influence the results of treating pernicious anemia with liver and liver substitutes. It is unpleasant to take. There seems no indication for its use.

RUTIN THERAPY

QUESTION: What is the present status of rutin therapy?

ANSWER: Rutin is a glycoside which is said to be "effective in the treatment of conditions arising from high blood pressure associated with increased capillary fragility" (*THE JOURNAL* 131:743 [June 29] 1946. Reports are conflicting, but it is doubtful whether capillary permeability is significantly influenced by the use of rutin.

RECENT ADVANCES IN THE TREATMENT
OF PULMONARY DISEASESJAMES J. WARING, M.D.
Denver

Without doubt the most important recent advance in the treatment of pulmonary diseases has been the use of antibiotics, especially the use of streptomycin in the treatment of pulmonary tuberculosis and its complications.

The following six organisms which cause an enormous amount of pulmonary disease either primarily or secondarily are highly sensitive to streptomycin in vitro:

Mycobacterium tuberculosis
Hemophilus influenzae
Hemophilus pertussis
Klebsiella pneumoniae
Pasteurella pestis
Pasteurella tularensis

It is further significant that with certain exceptions this in vitro sensitivity can be used and should be used as a good index of the possible effectiveness of the antibiotic in the treatment of infectious processes caused by these organisms.

Briefly I shall discuss: (1) the use of streptomycin in tuberculosis, (2) recent advances in the treatment of primary and secondary pulmonary diseases and (3) recent advances in the prevention of pulmonary diseases.

THE USE OF STREPTOMYCIN IN TUBERCULOSIS

If streptomycin were perfectly harmless, it could be given to every patient with active tuberculosis regardless of the nature and extent of the tuberculous disease and its complications. However, streptomycin is not perfectly harmless. This must not discourage us, since many of our most useful drugs are injurious if given unwisely.

Here let me say that although my personal experience with the use of streptomycin in tuberculosis has been meager, my experience with tuberculosis goes back forty years last month. The officers at Fitzsimons General Hospital have afforded me repeated opportunities to observe some of their cases. Moreover, John Barnwell, the physicians in the Veterans Administration and Corwin Hinshaw of the Mayo Clinic have given me the benefit of their experience with streptomycin.

In giving the public and the medical profession full information on what has been done with streptomycin in the treatment of tuberculosis, it is vitally important that neither the toxic effects nor the benefits be magnified on the one hand or minimized on the other.

About one thousand human beings with tuberculosis in one form or another have been treated with streptomycin. The most experienced men say that they have seen no patient who regretted taking the drug and no patient to whom they regretted giving the drug.

In what forms of tuberculosis should the drug be used? Without hesitation the drug should be given in tuberculosis meningitis with or without miliary tuberculosis of the lungs. In days gone by, all these patients died. Today streptomycin will save a few to live possibly many years in good condition. Some will have their lives prolonged only months but will relapse and die after surprising temporary improvements; others will survive a varying period but with lingering signs and symptoms of serious damage by the disease to the central nervous system. A few will survive but with complete loss of hearing, which may be due to the disease, perhaps to the drug—time will tell. The ultimate fate of these patients with tuberculous meningitis treated with streptomycin cannot yet be told; thus far the majority relapse and die. More time for observation is necessary. The highly significant thing is that streptomycin gives such dramatic evidence of ability to control in a few instances this most fatal form of tuberculosis.

In treating meningitis the drug must be given both intramuscularly and intrathecally. Doses of 0.5 to 2 Gm. in the spinal canal have produced in a few hours complete paralysis of both lower extremities with paralysis of bladder and bowels. If the patient does not die of the meningitis, complete recovery from the paraplegia with return of normal function of both bladder and bowels are to be expected. Even with the purest forms of streptomycin now available, not more than 100 mg. should be given daily intrathecally. The recommendations of the experts vary from 10 to 100 mg. I again remind you that we are dealing with a hitherto invariably fatal form of tuberculous disease. Unavoidable bad effects of the drug must be tolerated if useful life can be saved. Miliary tuberculosis of the lungs without meningitis responds sometimes even more dramatically than meningitis.

A number of patients with oral and pharyngeal tuberculous lesions, ominous complications, have completely healed these distressing local forms of the disease with streptomycin by intramuscular injection with or without streptomycin inhalations.

Tuberculous laryngitis and tracheobronchitis also seem amenable to streptomycin.

In general, the indications in pulmonary tuberculosis are to give the drug to patients with early, acute exudative lesions which are progressing despite good treatment along orthodox lines. Acute spread to the contralateral lung after thoracoplasty would seem to be a prime indication. Ordinary chronic fibroblastic tuberculosis with much fibrosis and cavity formation is not responsive to the drug. Streptomycin shows little or no effect on the caseous necrotic lesions, which are later often the cause of relapse. Collapse therapy and bed rest still play indispensable roles in treatment.

Finally, two questions must be answered. First, can streptomycin be given in effective doses and not at the same time render the patient for an indefinite period more or less deaf? The answer is yes, provided that by frequent audiometric determinations one catches the earliest sign of damage to hearing and stops the drug. How much good will have been done the patient by this time is unpredictable. The experts agree that deafness is not a serious or frequent toxic effect.

From the Department of Medicine, School of Medicine, University of Colorado Medical Center.

Read in a Panel Discussion on Recent Advances in Treatment before the joint meeting of the Section on Internal Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

The second and more important question is not so easily answered. Can streptomycin be given in remedial doses and not make life for the patient more or less miserable if not hazardous for an indefinite period because of damage to the sense of equilibrium? More experience is needed before final answer can be given to this question. Some of the experts are frankly pessimistic, while others are hopeful that one way or another damage to the vestibular branch of the eighth nerve can be avoided or minimized.

Basic requirements for the intelligent use of streptomycin in tuberculosis are adequate clinical experience with the natural history of the disease and its often surprising variations and a knowledge of its pathology. Thus fortified the clinician will know when to step in with streptomycin to the best advantage of his patient.

As to the future of "antibiotic" therapy in tuberculosis, four possibilities exist: (1) that streptomycin will be altered by the chemists' retaining and even enhancing its antibiotic effects but getting rid of its peculiar and specific neurotoxic effect; (2) that combined or alternating use of streptomycin with other antibiotics against the tubercle bacillus may be more helpful than treatment with one antibiotic alone; (3) that clinicians can arrange a dose schedule or method of administration by which damage to the eighth nerve can be avoided even if the chemists cannot improve the drug, and (4) that a new, safer and more potent antibiotic against the tubercle bacillus may be discovered.

PRIMARY AND SECONDARY PULMONARY CONDITIONS

Of fundamental importance to good chemotherapy of pulmonary diseases are: (1) identification of the organism causing the infectious process; (2) determination of its sensitivity to one or more antibacterial agents (penicillin, streptomycin, sulfonamide drug, etc.); (3) repeated tests, especially in chronic pulmonary diseases, for changes in bacterial resistance and predominant flora, and (4) timely blood cultures.

As to methods of antibiotic therapy, aerosols have their advocates but the preferred method nearly always is intramuscular injection. Aerosols are troublesome, often irritating to the mouth and throat and certainly not as effective.

Taplin and Bryan of Rochester, N. Y. have devised apparatus and a method for the production and inhalation of micronized antibacterial agents. This method of administration awaits adequate clinical trial.

Tularemia pneumonia, recognized early, is the ideal disease to treat with streptomycin.

Hemophilus influenza infections of the respiratory tract respond well to combinations of sulfadiazine and streptomycin. Acute inflammation of the epiglottis due to this organism with obstruction of the airway requires tracheotomy and sulfadiazine.

Pneumonia due to Klebsiella pneumoniae must be recognized early and treated vigorously with streptomycin.

The pneumonitis that formerly progressed to abscess of the lung, if recognized early and treated vigorously with both sulfonamide drugs and penicillin, may resolve without formation of cavity.

Since Pasteurella pestis is highly sensitive to streptomycin, it may be hoped that streptomycin will save some of the patients with pneumonic plague.

Aspiration pneumonitis may be prevented or cured by timely and skilful bronchoscopic aspirations of retained secretions plus the use of penicillin.

The combined use of sulfonamide drugs, penicillin and streptomycin parenterally, by intratracheal instillation and by inhalation will not alter the irreversible changes of chronic bronchiectasis but will make unavoidable lobectomy safer. Without doubt chemotherapy has made thoracic surgery almost as safe as abdominal surgery.

I direct your attention to the statement made by Bryan Blades that in World War II the death rate of troops from chest wounds was the lowest ever recorded in the history of warfare. Blades said that the reduction in mortality rate from 24.5 per cent in World War I to 8.1 per cent in the recent conflict was due not so much to technical improvements but to skilful preoperative management and judicious timing and selection of surgical procedures.

Mention should be made here of the Blalock-Taussig and other operations for the improvement of deficient circulation to the lungs and the transformation of the pulmonary-circulatory invalid with congenital heart disease into a reasonably well person.

PREVENTION OF PULMONARY DISEASE

A. Immediate Prevention.—Here should be mentioned once more the use of sulfonamide drugs and penicillin (1) to prevent postoperative pulmonary complications, especially after thoracic surgery and (2) to prevent aspiration pneumonitis; the use of streptomycin to prevent acute tuberculous spread to the other lung after thoracic surgery; the use of anticoagulants or venous ligation or both to prevent pulmonary embolism.

Your attention is again directed to the poliomyelitis exhibit of A. B. Baker and the Minneapolis group. In the treatment of certain forms of bulbar poliomyelitis, they have shown the great value of timely tracheotomy, judicious aspiration of bronchial secretions, the avoidance of hypoxia and the use of penicillin in the prevention of pulmonary complications.

B. Remote Prevention.—1. Vaccination against influenza viral infections is promising. 2. This country has been slow to approve BCG (bacillus Calmette Guérin) vaccination against tuberculosis. At least two medical schools in this country are using BCG to protect medical students and nurses. Before this decade runs out it seems likely that highly exposed groups and highly susceptible sections of our population will be offered the protection against tuberculosis that is promised by BCG vaccination.

CONCLUSION

Universal and conscientious application of the following four procedures will powerfully assist the campaign against tuberculosis: (1) mass roentgen examination of entire communities; (2) routine roentgenograms of the chests of those admitted to general hospitals; (3) more frequent sputum examinations by general practitioners, and (4) BCG vaccination of highly exposed groups and highly susceptible sections of our population. Only recently has the importance of these procedures become adequately appreciated.

ABSTRACT OF DISCUSSION

MINIMAL TUBERCULOSIS AND STREPTOMYCIN

QUESTION: Why not treat minimal tuberculosis with streptomycin?

ANSWER: At present—please note that I emphasize at present—physicians with the largest experience with the use of streptomycin are unwilling to use streptomycin in the treatment of minimal pulmonary tuberculosis for the following reasons: 1. The vast majority of these patients will get well without streptomycin. 2. The drug is toxic and the immediate and remote bad effects are not accurately predictable. 3. The development of "bacterial resistance" may leave the patient with an incompletely eradicated infection due to an organism now highly resistant to streptomycin. Ninety-five to 97 of 100 patients with minimal pulmonary tuberculosis will get well with the usual orthodox treatment without streptomycin. Don't shoot at a dickiebird if shooting will leave you with empty gun in the path of a tiger! It is impossible at the onset of their disease to predict which of the hundred will be the 3 or the 5 patients who will do badly and should have streptomycin to prevent spread of their disease. If the drug were perfectly harmless it could be given to all and accurate prophecy would be of no importance. Unfortunately practically every patient taking 2 Gm. of streptomycin daily for three to four weeks will have damage to vestibular function and a few may become more or less deaf. Improvement in the drug, modifications of dose schedule or methods of administration or combination with another antibacterial agent or discovery of a safe, more potent antibiotic may make it possible to use chemotherapy for every patient with tuberculosis. It may be overoptimistic to say that this day is close at hand! As for "bacterial resistance," this is a disturbing phenomenon which is being studied intensively.

HOME TREATMENT WITH STREPTOMYCIN

QUESTION: Can streptomycin be used in the home for treatment of tuberculosis?

ANSWER: The best place (the only place according to experts) for a tuberculous patient taking streptomycin is in the hospital or sanatorium under the supervision of a physician competent in diseases of the chest and experienced in the use of streptomycin. It can be formidable if not impossible to treat a patient with tuberculous meningitis in his home. Since intrathecal injections of streptomycin frequently cause temporary paralysis of bladder and bowels the difficulties of the nursing problem at home would be multiplied. It is also difficult to imagine a patient able to pay for 2 Gm. of streptomycin daily and at least two visits daily by his physician and nursing care besides and not able to go to a hospital. Tuberculous adenitis with or without sinus, all tuberculous fistulas, tuberculosis of the mouth, pharynx and larynx and acute tuberculous spread in the lungs all could be treated at home if absolutely necessary. Certainly, if a patient could not pay for sanatorium care and streptomycin but could pay for streptomycin only, I would give him his chance at home. In view of the serious disturbance of equilibrium which may result from streptomycin, no physician should undertake to use streptomycin in tuberculosis without sufficient preparation. He must have (1) adequate experience with diseases of the chest; he must have (2) studied the scientific exhibits on streptomycin at this hundredth anniversary of the American Medical Association; he should have (3) conferred with those who have used the drug in the treatment of tuberculosis, and (4) he should have familiarized himself with the published reports on the use of streptomycin. I recommend particularly (1) Carl Muschenheim's fine article "The Streptomycin Treatment of Tuberculosis" (*New York Med.* 3:17 [May 20] 1947); (2) T. F. Paine, R. Murray and M. Finland: "Streptomycin: I. Bacteriologic and Pharmacologic Aspects; II. Clinical Uses" (*New England J. Med.* 236:701 and 748 [May 8 and May 15] 1947), and (3) "Symposium on Streptomycin" (*Am. J. Med.* 2:419 [May] 1947).

MICRONIZED THERAPEUTIC AGENTS

QUESTION: What is the micronized method of giving antibiotics?

ANSWER: In *Science* for May 9, 1947 will be found an article "Administration of Micronized Therapeutic Agents by Inhalation or Topical Application" by George V. Taplin and Fred A. Bryan of the University of Rochester, Rochester, N. Y. Taplin and Bryan have devised apparatus for the grinding of certain therapeutic agents to a very fine or "micronized" state. They have also devised the apparatus for the administration of this finely ground powder by inhalation. Although this method has not yet had adequate clinical trial, preliminary reports indicate that therapeutic concentrations in the blood may be easily secured and maintained. The clinical and bacteriologic responses to this treatment have been excellent in more than 40 cases of various diseases in which penicillin therapy was indicated. Taplin and Bryan stated that patients prefer this type of treatment to either intramuscular injections or aerosol inhalations. Of further interest is that local sensitivity reactions to penicillin in the last 35 cases were eliminated by the incorporation of 2 to 5 mg. of finely ground diphenhydramine hydrochloride in each dose of penicillin. If it will be possible to give streptomycin by this method in smaller but effective doses to tuberculous patients, it would prove a most important discovery.

MEDIASTINAL LYMPHADENOPATHY

QUESTION: What course of therapy would you pursue for patients who have undiagnosed bilateral mediastinal lymphadenopathy?

ANSWER: Exploration of the chest by an experienced thoracic surgeon is just as safe as exploration of the belly by an average surgeon. In other words, exploratory thoracotomy is not yet quite as safe in average hands as exploratory laparotomy. Sulfonamide drugs, penicillin and streptomycin have certainly reduced the risk, however. Note Meade's recent report of 236 lobectomies with only one death. My colleague, Col. John B. Grow of Denver, who is a skilled thoracic surgeon, is convinced that it is unwise, unscientific and unjust to make a diagnosis of Hodgkin's disease on the basis of presumed favorable response to irradiation of the mediastinum. He thinks it much better to do a diagnostic mediastinotomy and secure a piece of tissue or gland for diagnosis. The well known tendency of Boeck's sarcoid to improve spontaneously is one source of error. Perhaps he is right, but the fact remains that occasionally the surgeon is unable to make a diagnosis without removing the lung or a lobe of the lung, with the result that a major operation is done unnecessarily. Since five year cures of cancer of the lung after pneumonectomy are very few, and since it is likely that late diagnosis is partly responsible for this discouraging state of affairs, both surgeon and physician must collaborate to secure earlier diagnosis. More frequent diagnostic thoracotomy offers one way of arriving at an early diagnosis. In this matter of early diagnosis of malignant diseases of the lung, I would urge the importance of three most useful procedures: (1) roentgen examination of the chest of every patient admitted to a general hospital; (2) more frequent resort to bronchoscopic examination, and (3) examination of fresh sputum obtained at bronchoscopic examination for tumor cells and incidentally for tubercle bacilli.

CARCINOMA OF LUNG

QUESTION: Under what circumstances would you recommend surgical treatment of carcinoma of the lung?

ANSWER: I am pessimistic about the prognosis of cancer of the lung even when the diagnosis has been made early and even when the surgeon is very experienced. At this date the five year cures after surgery are no more than 5 per cent. This figure should be greatly improved with increasing knowledge of diseases, greater uses of the roentgen ray and improved methods of diagnosis such as staining bronchial secretions for tumor cells.

STREPTOMYCIN IN ACTIVE TUBERCULOSIS

QUESTION: What is the place of streptomycin in the treatment of the usual case of active pulmonary tuberculosis?

ANSWER: Streptomycin should be used in the early acute exudative types of pulmonary tuberculosis. The patient will be subjected to unnecessary risks and expense if streptomycin is given for the usual fibroulcerative case of pulmonary tuberculosis. At this time, streptomycin cannot be recommended for the treatment of (1) minimal pulmonary tuberculosis, (2) chronic fibroid or fibrocaceous pulmonary tuberculosis, (3) acute destructive and apparently terminal types of pulmonary tuberculosis or (4) chronic tuberculous empyema.

TUBERCULOSIS SANATORIUMS

QUESTION (Dr. George J. Boines, Wilmington, Del.): Do you advise the use of streptomycin for general use in state tuberculosis sanatoriums?

ANSWER: It all depends on what you mean by "general use." I think that streptomycin should be available for selected cases in all tuberculosis sanatoriums.

TUBERCULOUS SINUS

QUESTION (Dr. Victor Siegel, Red Banks, N. J.): Can streptomycin be used for tuberculous empyema sinus?

ANSWER: Many cases of tuberculous sinus are improved by streptomycin. How much good will result from the use of streptomycin in "tuberculous empyema sinus" will depend on the size and pathologic state of the empyema "pocket" and also on the state of the underlying pulmonary parenchymal disease.

FAILURE OF STREPTOMYCIN IN EMPYEMA

QUESTION (Dr. Alexander Tish, Washington, D. C.): Why has streptomycin intrapleurally been of little or no value in tuberculous empyema and how can the failure be explained?

ANSWER: Streptomycin is of little or no value in tuberculous empyema because of the pathologic nature of this serious complication of pulmonary tuberculosis. It must be understood that streptomycin is helpful in early acute exudative pulmonary tuberculosis and has little or no effect on caseating lesions. It is likely that in tuberculous empyema innumerable small as well as large caseating lesions are located in the pleura and in the underlying lung. Hinshaw thinks that the pH of the empyema fluids may interfere with the bacteriostatic action of the drug.

HOW TO AVOID BAD EFFECTS OF STREPTOMYCIN

QUESTION (Dr. Sixto Y. Orosa, Bacolod, Philippines): Kindly suggest a plan for the administration of streptomycin for the treatment of pulmonary tuberculosis to avoid the bad effects on the patient.

ANSWER: In answering this question I should like it clearly understood that the suggested dose schedule has not been used long enough either to prove its efficacy or its harmlessness. I am convinced that daily doses of 2 Gm. for a period of one hundred and twenty days is too much. It seems possible already from animal experiment and clinical trials that a smaller daily dose in an intermittent schedule may be both effective and harmless. Suggested schedule of treatment: 1. Give 200 mg. of streptomycin intramuscularly every three hours; begin at 6 a. m., and give five doses in the twenty-four hours; not more than 1 Gm. daily. 2. Follow this schedule for two weeks; then stop for one week. Resume for two weeks, and stop for one week. 3. This schedule may be repeated for approximately one hundred and twenty days of actual administration of the drug. Time will tell whether this length of time and dose are optimal.

TUBERCULOSIS OF THE SKIN

QUESTION (Dr. Michael Margolies, Coatesville, Pa.): Is streptomycin of value in treating tuberculosis of the skin?

ANSWER: Experience is lacking to give adequate answer to this question.

"PROMIN" FOUND WANTING

QUESTION (Dr. S. A. Bolosky, Philadelphia): Has "promin" (sodium p,p-diaminodiphenylsulfone-N,N'-dixetrose sulfonate) by injection or "promizole" (4,2-diaminophenyl-5'-thiazolylsulfone) by mouth been given a long enough trial in pulmonary tuberculosis?

ANSWER: It is possible that combinations of streptomycin with another antibacterial agent such as "promin" or "promizole" may be more effective than the use of streptomycin or "promin" or "promizole" alone. A combination of streptomycin with some other bacterial agent may have the advantage of permitting the use of smaller and less toxic doses of streptomycin. Much work needs to be done on the synergistic action of antibacterial agents. "Promin" by injection and "promizole" by mouth have been weighed clinically and found wanting.

WHAT'S NEW IN ENDOCRINOLOGY

WILLARD O. THOMPSON, M.D.
Chicago

The object of this paper is to discuss the more important therapeutic advances that have occurred recently in the field of endocrinology. The most significant contributions have perhaps been those dealing with the use of antithyroid drugs and radioactive iodine in the treatment of toxic goiter and those dealing with the relation of androgens and estrogens to carcinoma of the prostate and breast respectively.

THE PITUITARY

Anterior Lobe.—Our knowledge of pituitary function has increased still further. Interesting developments have been the isolation in Evans' laboratory in the University of California of an adrenocorticotrophic hormone and of a purified growth hormone. Preliminary reports on the effects of the adrenocorticotrophic hormone are contradictory. According to Thorn and others¹ it caused stimulation of all the known functions of the adrenal cortex in 2 patients with pronounced hypopituitarism. According to other observers² it does not affect the excretion of sodium and chloride. Further observations will be necessary to determine the precise status of this material. It is available at the present time for experimental use in only a few laboratories. Addison's disease is sometimes caused by atrophy of the adrenal cortex as a result of inadequate stimulation by the anterior lobe of the pituitary. On theoretical grounds it would be desirable to treat the disease in such instances with a suitable pituitary extract. No evidence is yet available as to whether prolonged administration of adrenocorticotrophic hormone results in the development of antibodies which inhibit its effect. Most pituitary extracts available in the past have not been suitable for routine clinical use because of the temporary nature of their action. Preparations of the thyrotrophic hormone will temporarily cause an

From the Department of Medicine, University of Illinois College of Medicine, and the Henrotin and Grant hospitals.

increase in basal metabolism in many patients in whom there is any thyroid tissue capable of function. The metabolism always returns to its initial level or even a lower level with prolonged administration. The longest period of increase in basal metabolism which I have observed in man during the administration of thyrotropic hormone has been nine weeks.

Some of the newer preparations of pituitary gonadotropin in powder form have caused some stimulation of ovarian function. In a few women with secondary amenorrhea it has been possible to induce menstruation and in a few women with anovulatory menstrual cycles it has been possible to induce ovulation.

The new preparation of the growth hormone developed by Evans is of interest but so far has not been tried adequately in man. Preparations of the growth factor available up to the present have not proved very effective in clinical medicine. Engle and others³ have observed temporary growth in a pituitary dwarf with a preparation of the growth factor.

The observations of Markee, Sawyer and Hollinshead⁴ that the hypothalamus plays a major role in the release of luteinizing hormone from the anterior lobe of the hypophysis is of importance because of the influence that neurogenic factors appear to play in the control of endocrine function.

Multiglandular Deficiencies Secondary to Hypopituitarism.—In patients showing decided loss of pituitary function such as those with chromophobe adenoma of the pituitary and hypopituitary cachexia (Simmonds' disease) evidence has been obtained of the presence of hypothyroidism, hypofunction of the adrenal cortex and hypogonadism. Thus patients with chromophobe adenoma of the pituitary may show a very low level of basal metabolism, a low blood pressure, reduction in the concentration of sodium in the serum, increase in the secretion of sodium in the urine, reduction in the fasting blood sugar and various evidences of hypogonadism, including atrophy of the genitalia, amenorrhea and impotence. Patients with pronounced hypopituitarism sometimes show typical addisonian crises which have to be treated with the parenteral administration of large doses of adrenal cortex extract and the intravenous administration of sodium chloride and dextrose. They also suffer from attacks of hypoglycemia which are difficult to distinguish from addisonian crises. Patients with deficiency of the adrenal cortex secondary to hypopituitarism do not appear to become pigmented as frequently as patients with Addison's disease caused by destruction of the adrenal glands.

Posterior Lobe.—A few interesting reports have appeared on the posterior lobe of the pituitary, but no outstanding advances have been made. The most practical development has been further demonstration of the fact that diabetes insipidus may be controlled satisfactorily either by insufflation of posterior pituitary powder into the nasal cavities or by the intramuscular injection of "pitressin tannate in oil."

THE THYROID; TOXIC GOITER

Three important developments have occurred in the treatment of toxic goiter: (1) irradiation of the pituitary, (2) the use of antithyroid drugs and (3) the use of radioactive iodine.

Irradiation of the Pituitary.—A close relationship exists between the anterior lobe of the pituitary and the thyroid. The following effects of administration of the thyrotropic hormone have been observed in man: (1) increase in basal metabolism in all patients except those with complete myxedema; (2) production of thyrotoxicosis in patients with nontoxic goiter; (3) production of a syndrome resembling exophthalmic goiter in patients with a normal or slightly subnormal level of basal metabolism, and (4) increase in the severity of toxic goiter.

As has been pointed out, the increases in basal metabolism have always been temporary and have disappeared with continued administration over a period of eight to nine weeks. In a few patients with exophthalmic goiter, prolonged administration appears to have resulted in a cure. Following the initial increase, the basal metabolism has dropped to the normal level and remained there. Exophthalmos has not been reported in man as a result of the administration of the thyrotropic factor but it has been observed in various experimental animals. Hyperthyroidism secondary to hyperpituitarism has been noted in some patients with acromegaly, and hypothyroidism secondary to hypopituitarism has been noted in patients with chromophobe adenomas of the pituitary and in those with Simmonds' disease and anorexia nervosa.

The evidence available supports the hypothesis that the thyroid is only one link in the chain of events leading to the development of the symptom complex known as toxic goiter. Overstimulation by the pituitary appears to be an important factor. The cause of the stimulation of the pituitary has not been definitely determined but is probably related to some disturbance in the hypothalamus. Attempts to treat the disease by removing or destroying the thyroid probably do not attack the fundamental cause.

I have attempted to apply the knowledge of the pituitary-thyroid interrelations by irradiating the pituitary in a series of 43 patients with toxic goiter. A permanent remission was produced in about one third of them. These observations are of great importance from the standpoint of the mechanism which may be involved in the development of toxic goiter. However, it is not recommended that irradiation of the pituitary be used for the routine treatment of toxic goiter at the present time, chiefly because the percentage of cures is too low. Theoretically, this treatment might result in damage to other functions of the pituitary and to important structures in the base of the brain above the pituitary. Several years have now elapsed since these patients were treated and so far untoward early or late complications have not been observed.

Antithyroid Drugs.—Thyroidectomy, antithyroid drugs and radioactive iodine affect the thyroid directly and probably do not attack the underlying cause of the disease. In actual practice, control of the thyrotoxic phase of toxic goiter has proved to be a satisfactory form of treatment. The two antithyroid drugs most commonly used have been thiouracil and propylthiouracil. Propylthiouracil produces fewer toxic reactions than thiouracil but is not free from danger. These drugs have been used in two ways, namely, to treat the disease medically and to prepare patients for operation.

4. Markee, J. E.; Sawyer, C. H., and Hollinshead, W. H.: Activation of Anterior Hypophysis by Electric Stimulation in the Rabbit, *Endocrinology* 35:345-357 (June) 1946.

Medical Management: Sufficient time has not yet elapsed to determine the percentage of cures produced by thiouracil and propylthiouracil. The evidence available indicates that when the basal metabolism is maintained at the normal level with these drugs for periods of nine to twelve months, no recurrence of the disease is noted after omission of treatment in about 60 per cent of patients. The percentage of cures appears to be related to the length of time that the basal metabolism is maintained at the normal level before treatment is discontinued. The longer the drug is administered the higher the percentage of cures. Patients who are not cured by an initial course of treatment may show disappearance of the disease following a second or third course. Great caution must be used in concluding that toxic goiter has been cured by drug therapy because of the tendency of the disease to show spontaneous remissions and relapses and the observations of recurrence of the disease after many months of drug therapy. It will take several more years to determine the percentage of cures following adequate periods of administration. The development of these drugs represents an important advance in the treatment of toxic goiter, but they are not the final answer to the problem. In order for a drug to be satisfactory for medical management it must produce a cure in nearly all patients without producing toxic reactions. It is desirable to continue the observations already begun on the medical management of the disease in order to obtain more precise data on the percentage of cures. It is generally agreed that antithyroid drugs are valuable in the treatment of persistence and recurrence of toxic goiter following subtotal thyroidectomy and in the treatment of patients who present poor surgical risks; e. g., some older patients with cardiac decompensation.

Surgical Management: The introduction of anti-thyroid drugs, particularly propylthiouracil, represents an important advance in the preoperative preparation of patients with toxic goiter. With these drugs it is possible to eliminate the thyrotoxicosis completely in most instances, whereas iodine usually controls the disease only partially. Propylthiouracil is of the greatest value in the preoperative preparation of patients who have thyrotoxicosis in severe form, and these are the patients who have presented the most serious operative risks. With proper preparation, the mortality from thyroidectomy for toxic goiter has dropped almost to the vanishing point. Hospitalization of patients during the preoperative period is not necessary except in the presence of a crisis or some complication such as cardiac decompensation. Propylthiouracil is given until the basal metabolism drops to within normal limits. Iodine is then administered in addition to propylthiouracil for one week preceding operation in order to reduce hyperplasia and the danger of oozing of blood at the time of operation. Throughout the preoperative period the patient is given a diet high in calories. Operative procedures may be carried out a few days after admission to the hospital, thus greatly reducing the cost of hospitalization. Propylthiouracil may be discontinued at the time of operation but the administration of iodine is kept up until discharge from the hospital.

Radioactive Iodine.—The use of radioactive iodine represents an ingenious attack on the thyroid itself in patients with toxic goiter. Thyroxine contains 65 per

cent of iodine by weight. When small amounts of iodine are administered, the iodine is taken up almost entirely by the thyroid gland and, if radioactive, destroys many of the thyroid cells. An end result of such therapy is the development of areas of fibrosis in the thyroid gland. Myxedema may be caused by the administration of radioactive iodine to experimental animals. When given to patients with toxic goiter in proper amounts, it produces a cure in a large percentage of patients. As improvement sets in, the thyroid gland decreases in size. Patients receiving this form of treatment have not yet been followed long enough to determine the percentage of cures and the incidence of late complications, if any. No instance of carcinoma has been reported among patients followed up to the present time. In a few patients some temporary hoarseness has developed. Seidlin, Marinelli and Oshry⁵ have recently reported striking improvement in a patient with hyperfunctioning metastases of adenocarcinoma of the thyroid. However, most carcinomatous cells do not produce much thyroxine and take up little radioactive iodine. This material is, therefore, not of much value in most patients with carcinoma of the thyroid.

Malignant Exophthalmos.—In most patients with exophthalmic goiter the prominence of the eyes becomes grossly less when the basal metabolism is reduced to the normal level. In a few instances the prominence of the eyes continues to increase in spite of adequate control of the thyrotoxicosis. Some observers are of the opinion that this phenomenon is more apt to occur if the basal metabolism is subnormal. The exophthalmos sometimes becomes so pronounced that it is impossible to protect the eyeball by closing the lids. Increase in the prominence of the eyes in spite of a normal or subnormal metabolism indicates that the cause of the disease is still active. Exophthalmos has been produced in experimental animals with thyrotropic factor from the pituitary. Dobyns⁶ has recently described the organic changes in the orbit associated with the administration of thyrotropic factor to animals.

The treatment of malignant exophthalmos is unsatisfactory. Radical measures should be employed only when it is impossible to avoid complications with medical treatment, which includes the combined administration of iodine and desiccated thyroid and irradiation of the pituitary. Surgical relief of malignant exophthalmos involves removing part of the orbit, usually the roof and part of the lateral wall. Most surgeons are not enthusiastic about the results of surgical intervention.

THE PARATHYROIDS

Several interesting reports have appeared on the parathyroids but no really new developments have occurred. Parathyroid tetany is now a relatively infrequent complication of thyroidectomy and its treatment has been perfected. It has been clearly demonstrated that if this disorder is treated adequately as soon as it is recognized, it does not reduce life expectancy and complications such as bilateral cataracts do not develop. Small doses of dihydrotachysterol supplemented with

6. Dobyns, B. M.: Studies on Exophthalmos Produced by Thyrotropic Hormone: Changes Induced in Various Tissues, and Organs (Including Orbit) by Thyrotropic Hormone and Their Relationship to Exophthalmos. *Surg., Gynec. & Obst.* 82:609-617 (May) 1946.

calcium salts by mouth provide the best form of treatment. Vitamin D in large doses is also effective in promoting absorption of calcium salts from the gastrointestinal tract and may be employed in the treatment of parathyroid tetany if dihydrotachysterol is not available.

THE ADRENALS

Some progress has been made in the development of new synthetic products which substitute for the adrenal cortex. The synthetic material desoxycorticosterone acetate affects sodium and potassium metabolism but not carbohydrate metabolism. In the form of pellets implanted subcutaneously it has proved to be a fairly satisfactory method of treatment. Not all patients tolerate the material well, and in them it is necessary to use adrenal cortex extract. Other products, such as 11-dehydrocorticosterone, are not available commercially but there is reason to believe that a synthetic product will soon be available that will affect sodium, potassium and carbohydrate metabolism. Sufficient data have now been collected to demonstrate that patients with Addison's disease may be kept alive for long periods of time. They do not have much reserve and are in great danger of having serious intercurrent infections at any time.

It has been my policy to rely on adequate substitution therapy with adrenal cortex extract or desoxycorticosterone acetate. Patients periodically have crises in spite of treatment that is adequate to maintain them under most circumstances. The reason for the failure is not clear. The maintenance requirement of patients varies greatly and their susceptibility to crises also shows great variation. When pellets of desoxycorticosterone were first used in treatment it was considered necessary to determine the maintenance requirement of patients by daily injections of this material. From the figure thus obtained for maintenance purposes, the known rate of absorption of this material from each pellet and the percentage of material supposed to be eliminated unused when it was given once a day by injection, it was possible to calculate roughly the number of pellets required for the initial implantation. It is now known that this procedure is impractical because pellets from different manufacturers vary in their rate of absorption. It is common practice at the present time to implant initially in the subcutaneous areolar spaces four pellets of 75 mg. each, or a total of 300 mg. If this amount is not adequate, additional pellets are implanted in increments of 150 mg. In most patients the initial implantation does not need to exceed 450 mg., but a few require as much as 600 mg. Before implanting pellets it is necessary to determine the response of patients to the daily parenteral administration of desoxycorticosterone acetate. A few patients do not tolerate this material well. Complications of its use are the development of hypertension, edema which may be generalized and the production of focal areas of necrosis in cardiac and skeletal muscle. These areas of necrosis in the heart muscle may so impair the circulation that death results.

Some progress has been made on the site of formation of the various principles of the adrenal cortex. Androgens are apparently produced in the reticular zone, while the cells of the outer layer appear to be devoted to the control of sodium and potassium metabolism. Numerous observations have appeared on the determination of 17-ketosteroids in the urine in health

and disease. In patients with Addison's disease the production of 17-ketosteroids is low because of destruction of the glands.

THE TESTES

Hypofunction.—Observations previously reported on the treatment of hypogonadism have been extended and confirmed. Chorionic gonadotropin has proved to be a satisfactory agent for stimulation therapy and testosterone propionate for substitution therapy. Chorionic gonadotropin will produce maximum stimulation of function only when the testes are capable of showing maximum response to stimulation. Persistence of hypopituitarism for a period of several years may result in irreparable damage to the testis so that it can no longer show a maximum response to stimulation. Under these circumstances, it is necessary to use testosterone propionate in order to produce the greatest possible change. One of the most important considerations in hypogonadism beginning early in life is the correct age for starting treatment. Treatment should be started at the age at which puberty normally sets in in order to insure maximum growth of the genitalia and prevent the skeletal abnormalities associated with hypogonadism. The male sex hormone will cause growth of the genitalia at any age in patients with a pronounced deficiency but the genital growth is not as great after as during the age of puberty. The uses and misuses of testosterone propionate have been discussed in a previous communication to this journal.⁷ It is contraindicated in older men in whom the presence of carcinoma of the prostate is suspected.

Sterility.—A great deal of interest has developed on the subject of sterility. The male is sterile in infertile marriages in about 20 per cent of the patients. Stimulation of spermatogenesis in patients with secondary hypogonadism is not very satisfactory. In a few instances it is possible to cause some stimulation with some of the newer pituitary gonadotropins prepared in powder form. In determining the cause of sterility, it is advisable to investigate the male first, because it is comparatively easy to make a careful study of the production of spermatozoa.

THE OVARIES

Menstruation.—Knowledge of ovarian function has gradually increased. Rossman and Bartelmez⁸ have recently reported that few women menstruate regularly at twenty-eight day intervals. Fluctuations of one to five days are to be expected, and the twenty-eight day period occurs only once in ten times. An unusually long or short cycle may occur at any time in any normal woman. Observations on the female macaque have indicated that preovulatory and postovulatory phases of the cycle vary independently of one another and that ovulation may occur at any time in either a long or a short cycle. Sevi⁹ has also demonstrated that ovulation may occur at any time in the first half of the cycle, even during the latter part of menstruation. These observations clearly show that the calculation of the so-called safe period on the basis of the expected date of the next menstrual period is unreliable.

8. Rossman, J., and Bartelmez, G. W.: Delayed Ovulation: Significant Factor in Variability of the Menstrual Cycle, *Am. J. Obst. & Gynec.* 52:28-32 (July) 1946.

9. Sevi, S.: Early Ovulation, *Lancet* 2:448-450 (Sept. 28) 1946.

There has been some development in pregnancy tests, although the Friedman modification of the Aschheim-Zondek procedure continues to be the most satisfactory method for routine clinical use.

An interesting observation has been the demonstration of changes in the early morning temperature during various phases of the menstrual period. In the premenstrual phase the temperature falls one or two days before the onset of menstruation. It falls further in the menstrual phase, sometimes to as low as 97 F., and then rises to between 98 and 99 F. In the follicular phase the temperature fluctuates between 98.4 and 99 F., and in the ovulatory phase it falls suddenly, usually about the fourteenth day before the onset of the next flow. It sometimes falls to as low a level as 97 F. and then rises suddenly. The luteal phase is characterized by a sustained elevation of temperature to 100 F. or more, which persists until one or two days before the next flow. There is a slight drop in temperature in the midluteal phase, corresponding to the estrogen peak. Determinations of temperature throughout the menstrual cycle have provided a simple method of determining the time of ovulation in many women.

Abnormal Bleeding in the Treatment of the Menopause.—Bleeding from the uterus may occur at any age following estrogenic therapy. This bleeding may sometimes be prolonged and excessive, particularly following large doses of estrogens, and may be particularly dangerous in women with fibroids. All women in whom estrogenic therapy is contemplated should have a careful gynecologic examination, and the presence of fibroids or carcinoma of the cervix or fundus are contraindications to its use. When estrogen-induced bleeding occurs it can usually be controlled with rest and ergonovine maleate but in occasional instances it may be necessary to perform a curettage to control it. In a few older women with fibroids the bleeding may be so prolonged and excessive that a hysterectomy is necessary.

In the treatment of the menopause an effort should be made to administer the minimum amount of estrogenic material that will control symptoms without inducing uterine bleeding. In actual practice it is not always easy to attain this ideal. Amounts of estrogen that are inadequate to control menopausal symptoms completely may induce uterine bleeding. If patients are carefully followed, those with fibroids and carcinoma of the cervix or fundus excluded, and the smallest dosage of estrogen administered that will control symptoms, treatment of the menopause is a safe and reliable procedure. Slight spotting which occurs periodically is not serious. Treatment should be discontinued until it disappears and then resumed. In most instances, when prolonged and excessive bleeding occurs with small doses of estrogenic material, it is best to discontinue treatment permanently.

Hypogonadism Before the Menopause.—Stimulation of the ovary with various gonadotropins is not very satisfactory. Chorionic gonadotropin is not nearly as effective in the female as in the male. Pituitary gonadotropin is sometimes effective in inducing menstruation in women with secondary amenorrhea and may cause ovulation in women with anovulatory cycles. In most instances substitution therapy with estrogenic material must be employed in the treatment of hypogonadism in

the female. There is some difference of opinion concerning the most effective estrogen. For most purposes, estradiol in some suitable combination such as the benzoate or the dipropionate appears to be the most satisfactory product, but there are many estrogenic preparations on the market which produce excellent results. In the female, as in the male, the optimum time for the treatment of hypogonadism is the age of normal puberty. It is only by starting treatment at this age that maximum genital growth can be induced and skeletal disproportions prevented. The difficulty is that the diagnosis of hypogonadism early in puberty is much more difficult in the female than in the male because the development of the ovary cannot be determined as readily as the development of the testis. When hypogonadism is the result of a primary defect of the ovary, it is permanent and treatment is necessary during a large portion of the patient's life. The ideal form of treatment is the cyclic administration of estradiol and progesterone in a manner that simulates their normal production, so that periodic uterine bleeding is induced.

HORMONE ASSAYS

The time has arrived when the practice of endocrinology cannot be carried out adequately without proper laboratory facilities. For purposes of correct diagnosis and checks on therapy, it is necessary to have available facilities for determining the production of various hormones and the estimation of the concentration of various other substances in the blood and urine. The determination of the basal metabolism is also an essential of any adequate endocrine laboratory. It is important to be able to determine the production of follicle-stimulating hormone, androgens, estrogens, adrenal cortical steroids, etc. Facilities for determining the presence or absence of pregnancy (chorionic gonadotropin) are indispensable. It is essential to be able to make simple chemical tests—for example, determinations of sugar, sodium, potassium, calcium, phosphorus, phosphatase, total protein, albumin, globulin, nonprotein nitrogen, uric acid, creatine and creatinine—in blood and urine. Roentgen examination of the skeleton is essential in determining the effect of glandular abnormalities on growth. Gynecologic examination, endometrial biopsies and examination of the vaginal smear may furnish important information.

RELATION OF HORMONES TO CARCINOMA

Carcinoma of the Prostate.—A few years ago Huggins¹⁰ reported that orchiectomy sometimes produced striking improvement in patients with carcinoma of the prostate. Metastases in bone sometimes disappeared after this procedure, on the basis of roentgen examination. Huggins originally reported the results of orchiectomy in 20 patients with advanced carcinoma of the prostate. All had demonstrable metastases or local infiltration beyond the prostatic capsule. In 2 patients there was no obvious improvement from the operation. In the remainder clinical improvement was obtained for varying periods postoperatively. Eleven patients died during the first two years after orchiectomy and 4 others died within thirty-six to sixty-three months. Two deaths were the result of intercurrent infection. The median survival time for the 15 fatal

10. Huggins, C.: Prostatic Cancer Treated by Orchiectomy: Five Year Results, J. A. M. A. 131:576-581 (June 15) 1946.

cases was sixteen months, with improvement during eleven months of this period. Five patients survived more than five years after orchiectomy. Of these, 4 showed no signs of disease and 1, although apparently well, had a tumor mass in the region of the seminal vesicles. It would be premature to suggest that actual cure of the disease has been achieved in any case. Huggins and Scott¹¹ have recently reported the effects of bilateral adrenalectomy in 4 men with rapidly growing metastatic carcinoma of the prostate after orchiectomy had failed to arrest the malignant growth. Two men survived only thirty-six and fifty-four hours after complete adrenalectomy. The third patient lived eleven days and the fourth patient one hundred and sixteen days. Adrenalectomy did not appear to prolong life in these patients. The urinary 17-ketosteroids fell to a level of less than 2 mg. per day. This observation furnishes the first direct proof that the chief sources of urinary 17-ketosteroids are actually the gonads and the adrenals. The advance of the malignant process in a man with low androgenic activity suggests a factor apart from the stimulating effect of testicular and adrenal androgens. To this factor Huggins has given the name "androgen independence." Huggins has expressed the opinion that androgen may be necessary for the development of carcinoma of the prostate but that once the process is set in motion it may continue without androgenic stimulation.

Reports are appearing from various clinics on the effect of surgical castration and functional castration with estrogens in patients with carcinoma of the prostate. All observers are agreed that striking initial improvement is produced in most of the patients and most observers feel that life is prolonged. Many patients have died of carcinoma of the prostate after initial improvement. Sufficient time has not yet elapsed to determine whether castration ever produces a permanent cure. It is Huggins' opinion that bilateral orchiectomy is a more effective procedure than the administration of diethylstilbestrol.

Carcinoma of the Breast.—For years it has been known that occasionally in women with carcinoma of the breast removal of both ovaries produces some improvement. Adair and others¹² have recently reported that functional castration of women by the use of testosterone propionate in oil often produces striking clinical improvement. This improvement may consist in a decided reduction in the size of the local lesion in the breast, a decrease in the size of the metastases in the neighboring structures and an improvement in the metastatic lesion in bone.

The results are by no means as striking as those of castration in carcinoma of the prostate. It is the impression of some workers in this field that testosterone propionate is primarily of value when bony metastases are present. For reasons which are not clear at the present time, after the age of the menopause estrogens are said to produce some improvement in soft tissue metastases, whereas before the menopause they are supposed to aggravate the condition. As time has gone on, most patients have died of carcinoma of the breast. Results, while interesting, are not nearly as conclusive as those in carcinoma of the prostate.

Carcinoma of the breast may be produced by administration of estrogen in certain mice, but, up to the present time, there is no evidence that the administration of estrogenic material causes carcinoma of the breast in women. Many women have been frightened through articles appearing in the lay press implying that use of estrogenic material in the treatment of the menopause is harmful and likely to produce carcinoma of the breast. It is significant that among the large numbers of women receiving estrogens for treatment of the menopause, carcinoma of the breast is rarely noted. The danger of development of cancer of the breast can therefore scarcely be used as an argument against the treatment of the menopause with estrogen.

THE PANCREAS

No important development has recently taken place in knowledge of the internal secretion of the pancreas. The use of various insulins has been perfected and gradually more is being learned about islet cell tumors of the pancreas which produce hypoglycemia.

One interesting observation has been that by Dixon and others¹³ at the Mayo Clinic and by Ricketts, Brunschwig and Knowlton¹⁴ at the University of Chicago on the effect of total pancreatectomy in a patient with diabetes mellitus. They noted that the total insulin requirement was unaffected by this operation.

700 North Michigan Avenue (11).

ABSTRACT OF DISCUSSION

TREATMENT OF THE MENOPAUSE

QUESTION: What is the most satisfactory endocrinologic treatment of the menopause?

ANSWER: About 40 per cent of women have no untoward symptoms following cessation of menstruation. These women require no treatment. The remaining 60 per cent have symptoms which vary in intensity from patient to patient. In some women the symptoms are severe and include frequent hot flushes, palpitation, nervousness and various psychic disturbances such as persistent depression and paranoia. The duration of the symptoms varies from a few months to many years and the duration of treatment varies accordingly. The best method of treatment is to give the minimum amount of estrogenic material that will control symptoms. There are a variety of synthetic and natural estrogens available for this purpose. Of the synthetic estrogens, diethylstilbestrol has been used most widely. The minimum dose that will control symptoms completely varies from 0.25 mg. to 1.5 mg. daily. Most women do not require more than 0.5 mg. daily. In these doses diethylstilbestrol rarely produces toxic effects, although various claims of superiority have been put forth for other estrogens, such as dienestrol. The synthetic estrogens possess the advantage of being very effective by mouth. Of the natural estrogens the most effective probably is estradiol. It is usually given in the form of the benzoate or the dipropionate and is more effective when administered intramuscularly than when given by mouth. The minimum dose required to control symptoms varies from 1.67 mg. every two weeks to 5 mg. twice a week. It is important to carry out a careful pelvic examination before instituting estrogenic therapy for the menopause. This form of treatment is contraindicated in women with carcinoma of the cervix and in most patients with uterine fibroids. In women with fibroids excessive bleeding may start, either during estrogenic therapy or after its withdrawal. Even in women whose uterus appears to be normal prolonged and excessive

bleeding may follow the prolonged administration of estrogen in large doses. Treatment should be interrupted every three or four months to determine whether it is still necessary and the patient should be followed carefully during treatment. It is probably best not to administer estrogen to any woman in whom the presence of carcinoma of the breast is suspected although it has been claimed that in women after the age of the menopause estrogenic therapy may be of some value in reducing the size of soft tissue metastases.

TREATMENT OF OBESITY

QUESTION: Are endocrine products useful in the treatment of obesity?

ANSWER: Obesity may or may not be associated with endocrine deficiencies although the presence of hypogonadism in patients with obesity is common. Desiccated thyroid may be employed in moderate doses (2 to 4 grains [0.12 to 0.25 Gm.] daily) under careful supervision to supplement a weight-reducing diet. Patients must be followed carefully during the administration of this material because in some instances symptoms of intoxication develop with small doses. Great care must be taken to avoid self medication with thyroid products. In adolescent boys suffering from the Frölich syndrome the administration of chorionic gonadotropin may produce a complete transformation without a weight-reducing diet. As a result of the stimulation of the production of the male sex hormone the muscles develop, shoulders become broader, hips narrower, and breasts and abdomen smaller. If the obesity associated with this condition is severe, it is necessary to supplement the administration of chorionic gonadotropin with the administration of a weight-reducing diet.

EXTRACTS OF ADRENAL CORTEX

QUESTION: For what conditions are extracts of adrenal cortical substances effective?

ANSWER: The most important indication for the use of adrenal cortex extract is the presence of Addison's disease. It is the only material that is effective in the treatment of a crisis of this disorder, whereas for maintenance therapy the synthetic material desoxycorticosterone acetate is preferred because of its low cost and the fact that it may be implanted subcutaneously in the form of pellets, thereby eliminating the necessity of daily injections. There are many reasons for believing that the cortex of the adrenal gland produces a material which plays an important role in the resistance of the body to trauma and infection. Administration of adrenal cortex extract has accordingly been tried in the treatment of shock, in the treatment of severe infections to supplement specific substances and in the treatment of patients who have severe reactions following surgical procedures. There are data which suggest that adrenal cortex extract is of some value in the treatment of these conditions. The cost of the material and its rather limited supply have prevented its adequate trial in conditions which have just been mentioned. In some instances the doses used have been too small to produce much improvement. In the presence of shock and overwhelming infection it is probably necessary to give the material in doses of not less than 10 cc. per hour.

RADIOACTIVE IODINE

QUESTION (Dr. Fred Kauffmann, Canton, Ohio): In what way can radioactive iodine be handled for practical purposes?

ANSWER: Radioactive iodine is not yet ready for routine clinical use. To treat patients with toxic goiter satisfactorily with this material there must be an adequate setup for measuring the dose administered and the amount of material taken up by the thyroid gland and the rate at which it disappears. The equipment necessary for this purpose is relatively expensive and its application requires specially trained personnel. Radioactive iodine has therefore been used in only a few clinics up to the present time. All radioactive material has to be handled with the greatest care because of serious consequences which may follow overexposure to the powerful rays emitted.

ABSTRACT OF DISCUSSION

The answers to the following questions were by Dr. Chester S. Keefer, Boston, whose original presentation comprised a lantern demonstration and was therefore not suitable for publication.

PENICILLIN BLOOD LEVELS

QUESTION (Dr. L. H. Hirsh, Milwaukee): What is the relation of blood levels to tissue levels in use of penicillin?

ANSWER: Penicillin diffuses into red blood cells in about 10 per cent of the concentration of that in the plasma. Very small amounts diffuse into the cerebrospinal fluid, even after large intramuscular or intravenous injections of penicillin. Penicillin can be found in pericardial, peritoneal, pleural, joint and edema fluid. The concentration in general is lower than that found in the blood at the same time. Little, if any, diffuses into the tears or saliva, or the pancreatic juice or the milk. It passes through the placenta from mother to infant. The amount present in placental cord blood is approximately 40 per cent of that found in maternal serum. It has also been ascertained that penicillin diffuses into the kidney, small intestine, lung, buccal mucosa, bile, skin, liver, adrenal glands, pancreas, heart, voluntary muscle and spleen. Practically none is found in the brain and bone marrow, even one hour after intravenous injection of fairly large doses. The dura mater, cornea, lens and vitreous humor contain no penicillin, and nerve tissue only traces. In brief, penicillin diffuses into various organs of the body in much lower concentration than that found in the plasma.

PENICILLINASE

QUESTION (Dr. A. C. Worley, Fort Wayne, Ind.): Do body cells develop penicillinase? If so, how long does resistance last?

ANSWER: There is no evidence that the body cells develop penicillinase. Penicillin is not inactivated by any of the body fluids, pus or necrotic tissue. Some bacteria, notably the *Staphylococcus* and the gram-negative bacilli, may produce penicillinase.

MIXTURES OF ANTIBIOTICS

QUESTION: Can streptomycin and penicillin be mixed in the same syringe?

ANSWER: Yes, there is no contraindication to mixing the two together for simultaneous injection.

BACITRACIN

QUESTION: Are there any new effective antibiotics?

ANSWER: The only new antibiotic that has been investigated on a limited scale is bacitracin. Dr. Meleney and his associates have used bacitracin locally for the treatment of infected wounds. It has the same general scope, as far as bacteria are concerned, as penicillin.

TREATMENT OF ORDINARY SORE THROAT

QUESTION: Do you think it advisable to treat ordinary sore throat with penicillin and/or sulfonamide drugs?

ANSWER: Yes. Most instances of sore throat are due to hemolytic streptococcus infection. Penicillin and/or the sulfonamide drugs can prevent suppurative complications and reduce the total number of days of illness.

STREPTOMYCIN NOT INFECTIOUS

QUESTION (Dr. Erling S. Wedding, Brooklyn): Have any strains of streptomycin ever been demonstrated to be pathogenic to man or experimental animals?

ANSWER: I do not know of any cases in which *Streptomyces griseus* has been responsible for infection in man.

ABSCESS OF THE LUNG

QUESTION (Dr. William Klein, New Brunswick, N. J.): Have you found a greater incidence of pulmonary abscesses following the use of penicillin in pneumonias?

ANSWER: From a study of the large number of cases reported to the Committee on Chemotherapeutic and Other

Agents of the National Research Council, there is no evidence that the use of penicillin in the treatment of pneumonias is followed by a larger number of pulmonary abscesses.

ORAL PENICILLIN

QUESTION (Dr. Charles P. Ryland, Washington, D. C.): Please discuss the efficacy of penicillin orally.

ANSWER: At least three to five times as much penicillin should be given by mouth as is given parenterally. It has been found to be extremely effective in the treatment of pneumococcus pneumonia, gonococcal urethritis, hemolytic Streptococcus infections of the throat and pharynx, and other mild or moderately severe infections that respond to penicillin.

STREPTOMYCIN TIME-DOSE RELATIONSHIP

QUESTION (Dr. Belle Jacobson, New Rochelle, N. Y.): Is it necessary to give streptomycin every three hours in the treatment of tuberculous meningitis?

ANSWER: There is not enough information available concerning time-dose relationships to make any precise statement concerning the time interval between the injections of streptomycin in the treatment of tuberculous meningitis. It is not unlikely that injections every six hours throughout the day will be adequate, for the reason that streptomycin is excreted by the kidney much more slowly than is penicillin.

UNDULANT FEVER

QUESTION (Dr. P. Blair Ellsworth, Idaho Falls, Idaho): What is the latest treatment for undulant fever?

ANSWER: The best results that have been reported in the treatment of undulant fever, particularly the early cases—that is to say, patients who have been ill for less than two weeks—have been from the combination of sulfadiazine and streptomycin. Streptomycin should be continued for at least four weeks in amounts of at least 2 Gm. a day; sulfadiazine should be continued for a similar period of time, depending on the reaction of the patient. In the chronic cases of undulant fever, the evidence is far from convincing that any of the chemotherapeutic agents are responsible in shortening the course of the disease.

INTRASPINAL INJECTIONS

QUESTION (Dr. George Vryonis, Alexandria, La.): What dilutions of penicillin and streptomycin should be used in intraspinal injections? What undesirable results may follow?

ANSWER: Penicillin should be diluted so that not more than 1,000 to 2,000 units per cubic centimeter of isotonic solution of sodium chloride are used. The maximum dose should be not more than 25,000 to 50,000 units in a twenty-four hour period. For streptomycin, the maximum dose in a twenty-four hour period should be 50 to 100 mg., diluted in 10 to 20 cc. of isotonic solution of sodium chloride. With low dilutions and a volume of solution that is equal to that which has been withdrawn after lumbar puncture, there are usually no undesirable effects. If on the other hand, one uses high concentrations and small amounts, headaches, meningismus and, rarely, convulsions may follow.

PERTUSSIS

QUESTION (Dr. Benjamin Feldstein, New York): Is streptomycin of value in the treatment of pertussis?

ANSWER: So few patients with pertussis have been treated with streptomycin that it is impossible to answer this question with certainty. A few patients with pertussis associated with pneumonia and fever have been treated with streptomycin with striking results. There are several studies under way at present, so that more information concerning the value of streptomycin in pertussis will be forthcoming.

COMBINED INJECTIONS

QUESTION (Dr. H. H. Schuman, Springfield, Mass.): Is there any contraindication to using both penicillin and streptomycin in a single combined injection?

ANSWER: There is no contraindication to using both substances in a single combined injection. They should both be made up freshly before injection.

TOLERANCE TO PENICILLIN

QUESTION (Dr. A. I. Rosenblum, Chicago): What is the present status regarding the development of tolerance to penicillin following repeated uses for different diseases?

ANSWER: There is no evidence that the use of penicillin repeatedly builds up a tolerance on the part of the patient to its effective use when infections occur.

DISTILLED WATER OR SALINE SOLUTION

QUESTION (Dr. L. C. Moeris, Chicago): Is it desirable to administer streptomycin in distilled water rather than in saline solution?

ANSWER: Streptomycin may be administered either in distilled water or in saline solution. There is some evidence that mixing streptomycin with isotonic solution of sodium chloride decreases its activity. This has been demonstrated in vitro, but so far there is no evidence that using streptomycin in saline solution for the treatment of infections in man has decreased its potency.

PROPHYLAXIS OF RHEUMATIC FEVER

QUESTION (Dr. J. L. Hrdina, Cicero, Ill.): Do you recommend the daily oral use of penicillin in the prophylaxis of rheumatic fever for long periods, say two to four years' continuous use?

ANSWER: No one has had any experience with the daily oral use of penicillin for two to four years continuously. There is some evidence, based on experience over the last two years, that penicillin given in amounts of 50,000 units twice daily will prevent Streptococcus sore throat when patients are under carefully controlled conditions. In this way the incidence of the recurrence of rheumatic fever may be reduced.

LEGAL LIABILITY

QUESTION: What legal liability can a physician incur at this time, knowing the possible permanent disabilities the patient will incur with the use of streptomycin?

ANSWER: I do not know. This is a matter that should be taken up with legal counsel in order to get a specific opinion.

ALLERGIC REACTIONS

QUESTION: I suggest a plea for more accurate reports on the allergic reactions following the injection of penicillin in wax and peanut oil. The incidence seems higher than 5 per cent and the distress to patient and physician much higher than 50 per cent. Can a different menstruum be made?

ANSWER: No menstruum has been developed other than peanut oil and white wax for adequately delaying the absorption of penicillin from local deposits. In a controlled series of cases studied by Dr. Harry Dowling in Washington, D. C., the incidence of allergic reactions following the injection of penicillin in oil and wax was 5 per cent. This is a personal communication from the investigator.

ANTIBIOTICS AND THE COMMON COLD

QUESTION: Is it worth while to give antibiotics in the treatment of the common cold or influenza?

ANSWER: There is no evidence that any of the antibiotics influence the course of influenza or the common cold.

A Vaccination Record.—In less than a month more than 6,300,000 people were vaccinated in New York City, over 5,000,000 of them within the two week period following the appeal for universal vaccination made by the Mayor. Never before had so many people in one city been vaccinated in such a short time and on such short notice. Thanks are due to the press and radio for giving so generously of their space and time to bring necessary information to the public. Had it not been for them and for the intelligent cooperation of the public and the generosity of private physicians and volunteer workers, notably from the American Red Cross and the American Women's Voluntary Services and former Air Raid Warden groups, it would have been impossible to have achieved this remarkable record.—Weinstein, Israel, M.D., An Outbreak of Smallpox in New York City, *American Journal of Public Health*, November, 1947.

Special Article

FOODS FOR EMERGENCIES

RUSSELL M. WILDER, M.D.

and

THOMAS E. KEYS, M.A.

Rochester, Minn.

"Our difficulties will be greatly lessened if we have a long-range food policy which will ensure that during the war and the postwar period, however poor the nation or part of the nation may be, every family will be assured of sufficient food to maintain them in health."—Sir John Orr and David Lubbock, *Feeding the People in War Time*, London, Macmillan & Co., Ltd., 1940.

Writing in 1942 on the subject "Unusual Foods of High Nutritive Value," we urged reevaluation of supplies of food, with emphasis on a number of resources which theretofore had not been tapped extensively and which warranted more consideration in developing plans for feeding populations for which supplies of food were limited. The undernutrition of hundreds of millions of the European population precipitated by the war and scarcely arrested, if at all, since the ending of hostilities, prompts reiteration of this subject. Also a number of the foods which we considered in our previous paper have assumed immense importance in many of the war-torn countries, and some account of this experience is now available for review.

Two general observations relate to this experience; each of them has been repeatedly affirmed. The first is that starvation in the European countries, bad as it has been, has everywhere been less than was anticipated from estimates of food supplies available. The second is that deficiencies of specific nutrients and especially deficiencies of vitamins have been relatively inconspicuous. The reasons include the fact that persons who are undernourished compensate to some extent by curtailing their activities. Children are less active in their play, and the work output of adults falls unconsciously. The growth of children is retarded. Likewise with subnutrition goes depression of basal energy exchange; in starvation the basal metabolic rate may be as low as minus 40, which represents a physiologic adjustment. The need for calories is restricted by these means, and loss of weight lags behind what would be expected were judgment limited to knowledge of the calories available. Also in consequence of diminished expenditure of energy the requirement for several nutrients is lessened and the appearance of signs of gross deficiency, either of vitamins or protein, is postponed. However, there is yet another reason for discrepancies between the loss of body weight anticipated and that observed. This, namely, has been the ability of starving populations to supplement their diets with edibles which are not included in customary estimates of food supplies. Thus some extra calories are obtained, and in addition, as a rule, the unusual foods consumed are often good or even excellent sources of minerals and vitamins. Thereby the diet as a whole in many European countries, although inadequate with respect to calories and providing much less animal protein and less fat than is desirable, has been relatively improved in certain

instances with respect to minerals and vitamins. Exceptions have been noted. In Spain, where for many people the staple foods were white bread and polished rice, the number of cases of mental and nervous disorders attributed to deficiency of B vitamins is reported to have increased greatly, in contrast to experience in Leningrad and Stalingrad, where hundreds of thousands died of starvation, but vitamin deficiency was not apparent.

We made comment in our previous paper that the diets of primitive populations, with food selection limited to unsophisticated foods, compared most favorably with the diets of those nations which are most advanced in general culture and whose people have certain silly notions about what is fit for food. Primitive man was constantly in danger of starvation from inadequate supplies of food, but the foods which he obtained from his natural environment were relatively rich in vitamins, in minerals and in protein. A happy custom of primitive man was to eat the entire carcass of his kill, including the intestine, which with the organ meats, notably the liver, was rich in vitamins. He ate these morsels first by preference, he drank the animal's blood, he was none too squeamish in his taste for fish, but took whatever he could catch and ate it whole. Snakes and rodents were delicacies, and insects, termites and the like, all rich in nutrients of the highest value, were quite acceptable. Wild fruits and vegetables were consumed either fresh as found or after a minimal period of storage. Later, with the development of agriculture, the cereal grains came into use, but so long as milling methods remained primitive these provided much more nutrient material than is obtainable from the highly processed cereals of modern mills.

The inhabitants of the European countries overrun by Germany reverted so far as they were able to the food ways of primitive people. Many products which in normal times were not considered fit for human use have been found acceptable in this time of need. The wheat and other grains available were ground whole for human use or milled to high rates of extraction, whereby, for example, from 100 parts of wheat from 85 to 100 parts of flour are produced, as compared to the 65 to 72 parts of flour yielded as white flour by the modern flour mill. No skim milk was allowed to go to waste, and the whey obtained from making cheese was utilized for food. Organ meats were cherished and in places even the blood of slaughterhouse animals was consumed. The populations of Europe were handicapped in this reversion to more primitive food ways by ingrained habits, by taboos, by lack of ingenuity and by numbers. The natural food environment of Europe may have provided enough in primitive times, but it falls far short of being ample for a population like that of modern Europe. Nevertheless, something could be done to eke out meager rations, and what was obtained by these and other means helped to alleviate the worst effects of famine.

"The bread is dark and soggy, made of several kinds of coarse grain," reads one report. Other than the rationed foods, and they provided only 1,500 calories daily, people could "buy" sea gulls, crows and strange fish which formerly were considered unfit for human consumption. Meat had disappeared, even horse meat. The women and children scoured the fields and roadsides for edible plants. The forests were finecombed for mushrooms and berries. Dandelions, nettles, acorns, leaves and nuts all had their uses. Every little plot of ground, even every window box, became a victory garden. That was in Norway. In Holland, tulip bulbs

and sugar beets were consumed as food. Both caused diarrhea when taken in large amount. Rhubarb leaves proved toxic. The same was true of beechnuts. Thus at times more harm than good resulted from the practice of foraging. In Germany, in the spring of 1947, when coarse bread was made from high extraction flour, this bread and potatoes were the foods principally responsible for a nutritional situation which otherwise would have been more serious than should have been expected from the ration. The diet largely consisted of bread and potatoes with a few beans and peas, a bit of cheese and a few onions. The fat allowance was 9 Gm. a day for adults. The weekly meat allowance was usually consumed at one meal.

EDIBLE WILD PLANTS

Weeds and other plants have been used as food by every famished population. The varieties available in Belgium were described by Hermans. The Russians resorted to cooking inedible greens to make a paste rich in carotene. This was eaten as a spread on bread. Sources of vitamin C were short in many countries. In England as well as on the Continent rose hips were collected and reduced to syrup or jelly. Pomegranate boiled and concentrated was used in Russia. Germinating grains have long been known to be a source of ascorbic acid. United States soldiers in the Pacific area were given a manual issued by the War Department which illustrated and described both edible and poisonous plants. It was intended as a guide for soldiers separated from their units and dependent on foraging for their survival. The manual covered all Polynesia, Micronesia, Melanesia, the Malay Peninsula and the Philippines. For practical purposes it also covered Indo-China, Thailand, Burma and Eastern Asia. An astonishing number of herbs, ferns, palms, grasses, tuber seeds and fruits were described as being edible and nutritious.

Issued in 1943 by the Office of War Information of the United States government was a list of edible weeds with directions for their preparation. Mentioned were dandelion, lamb's quarters, plantain, poke, purslane, wild chickory and dock. Some of these are to be found in every vacant lot and on other neglected ground. Others grow abundantly along roadsides and hedges or by streams and in the woods. A leaflet containing similar information was distributed by the New York Department of Health. Mentioned in it were milkweed, stinging nettle, summer mustard and sorrel. Mentioned also in a reference was a book entitled "Weeds" by W. C. Muenscher.

Among the edibles in nature which in emergencies can serve as food is the acorn, which held a place of importance in the diet of the American aborigine. After parching over coals the meat is sweet and palatable. It may be powdered to make a flour. Many wild plants served the Indians and early settlers of America. Among those noted by Carr are the tuberous roots of the catbrier or greenbrier (*Smilax*), the roots of the common cattail, the bulb of the sago lily and persimmons and poke weed.

'KITCHEN GARDENS

The kitchen garden has made an important contribution through these recent years of shortages of food in Europe, and gardens in America have helped to supplement the diet here and thus to release less perishable foods for export. Greater savings of food for export can be made by avoidance of waste, not only

waste of food itself but loss of the nutrients in foods during their handling and preparation in the kitchen. Efforts to teach this lesson during the war were not without effect. The problem is of supreme importance but not a part of the subject of this paper. By its national gardening program the Department of Agriculture is encouraging the continuation of the wartime garden program. City planners are encouraged to provide small garden plots for use by urban dwellers. Not only is the contribution of fresh food from the garden of the greatest value in nutrition, because fresh foods contain vitamins some part of which is lost when the foods are shipped to distant markets, but from the gourmet's point of view fresh foods contribute greatly to the attractiveness of the meal. No tomato tastes as good as one just picked, no lettuce, no sweet corn, no peas or green beans, no strawberries or melons can compare with those grown in one's own garden. Also the variety of food that can be made available is much greater than can be found in local markets. Millions of city and suburban dwellers with no previous experience became skilful gardeners in the war years and learned that gardens pay in increased health and satisfaction. Also many persons for the first time in their lives learned to eat these wholesome foods.

In England in the war the Ministry of Food allotted land from parks and other open spaces and provided blueprints for the gardens. The allotments were "10 perches" in size, a plot of about 300 square yards, say 30 by 90 feet (9.1 by 27.4 meters). A study of ninety-eight of these allotments showed an average production in one year of 411 pounds (186.4 Kg.) of potatoes and 1,088 pounds (493.5 Kg.) of other vegetables. The plan involved successive plantings, so that in the English climate it was possible to obtain a fairly even supply of products over the year. The amount was sufficient to meet the requirements for vitamins C and A for a family of five and to add importantly to the supply of other nutrients and calories.

POTATOES

Of all the vegetables, however, the one which aided most in the support of human life in war-torn Europe was the white or Irish potato. The Ministry of Foods in England guaranteed the growers a price for all surplus potatoes. Their distribution was well controlled and they contributed to the calories of the diet even more importantly than wheat. Drummond called bread and potatoes "buffer energy foods" because at the height of rationing in the United Kingdom they remained in adequate supply, unrationed, to serve as buffers for diets which otherwise would have been too low in calories.

The potato thus is properly regarded as a food of great value in emergencies. Unfortunately, the crop is not entirely dependable, and when great reliance has been placed on it failure of the crop has resulted in widespread famine. Another problem with potatoes is the high water content and thus the cost of transportation. This has limited the usefulness of potatoes for relief feeding abroad. The ocean freight alone is enough greater than that of flour so that flour at a cost of 6 cents a pound (13.2 cents a kilogram) has been less expensive than potatoes delivered free of charge to United States ports. Potatoes, furthermore, are sensitive to freezing. Great losses occurred in storage in Europe in the cold weather of 1942-1943.

For the several reasons mentioned it would seem to be desirable to provide for large scale processing of potato crops. Dehydration is a possibility, but is relatively expensive. Potato flour can be made rather inexpensively and has been reported as selling in a competitive market at only 8 cents a pound (17.6 cents a kilogram) which puts it in a class with wheat flour. Uses for potato flour should be thoroughly explored. Its admixture with wheat flour in making bread is a long-established practice, although little used since World War I. Many other uses could be found. Potatoes when properly prepared for eating make important contributions to the ascorbic acid content of the diet. Potato flour probably contains no ascorbic acid, but this difficulty could readily be corrected by suitable fortification. The nicotinic acid and thiamine of potatoes are presumably retained in processing to flour. Only about 40 per cent of the nitrogenous substance of potato is protein. The balance consists of amides, amino acids and purines; yet the biologic value in nutrition, although less than that of casein, is said to be superior to that of the combined nitrogenous substance of wheat, of which 90 per cent consists of protein. The principal protein in potato (tuberin) is not superior in value to the proteins of wheat, from which Chick and Cutting have concluded that some portion of the non-protein nitrogenous material must be utilized as protein.

PROTEIN RESOURCES

Shortage of protein of good biologic quality has been serious in many parts of Europe as well as in the Far East.

Blood.—In the winter of 1944-1945 plasma obtained from slaughterhouse blood played a part in Amsterdam in the treatment of famine edema. A pediatrician was the first to call for it. He wanted it for children in the 6 to 14 year age group, in which the mortality rate had risen rapidly from the time that supplies of rationed milk had been suspended. Two butchers were placed under supervision for the preparation of this plasma. Soon thereafter general practitioners began to use the product for patients with hunger edema. Benefit was observed with as little as 500 cc. per week. The fact that a dose of 6 Gm. of animal protein a day, which was all that this provided, was lifesaving led to the conclusion that lack of certain essential amino acids in the almost entirely vegetable diet had been responsible for the edema and for increased mortalities. The demand for the plasma increased so much that all slaughterhouse blood was used for this purpose. It was fed at first cooked in pancakes, later as bouillon or in brown bean soup. Whole blood, incorporated in sausage (Blutwurst), which had been consumed before in parts of Europe, was not acceptable in Amsterdam. Physicians, however, prescribed it for anemia. In Russia and in parts of Germany, whole blood was used in bread. In Switzerland, a mixture of potato and blood was recommended.

Fish.—The normal catch of fish by European fishermen was seriously diminished while war lasted, owing mainly to confiscation of trawlers and other fishing boats for wartime purposes. Fishing now is being stimulated by every means available in order to increase the supplies of protein. Unfortunately, only a relatively small proportion of the normal catch of fish is at present utilized for food. The balance is diverted to fishmeal fertilizer or is thrown away. The protein of this waste was separated by Deuel for study of its biologic activity. It equaled casein in potency for

regenerating plasma protein in animals made hypoproteinemic by exsanguination.

In addition to their value as a source of protein, small fish offer the advantage of containing edible bones, thus serving as a source of calcium. A report from India by Basu and his associates contained the account of a study of calcium balance made on human subjects who were given small whole fish as the only source of calcium. A daily intake of 70 Gm. maintained a positive balance. Calcium deficiency is prevalent in the rice eaters of Bengal and other parts of India where milk is not obtainable, and an active interest in this matter is apparent from numerous studies reported in the scientific literature of India. Aykroyd, in a consideration of Indian diets, pointed to the fact that India of necessity must be self contained as regards food supply and that the existing relation between population and the land necessitates a national diet composed of foods giving a high calorie return for each unit of the land. Attempts to increase the production of foods not falling within this category, foods such as milk or meat, present great difficulties. Adolph, writing on conditions in China before the war, made the comment that vegetarian people are usually vegetarian not because of dietetic whims but for economic reasons. The equilibrium between food supply and population is so delicate that disturbance of the status quo may be at once reflected either in emigration or in a mounting death rate from starvation. Cereals and legumes provide some 88 per cent of the calories consumed in China. This type of situation seems to us to call for great expansion of the fisheries, with due attention paid to Deuel's suggestion for more economy in the utilization of the catch. It can be maintained that an increase of the food supply in the Orient would only lead to further increase of the population. Our suggestion here, however, is not so much an increase of the total calories, but rather an improvement in the quality of the diet.

The amount of animal protein obtainable from the sea is almost limitless. Areas in which life is of unusual abundance are the North Sea, the Norwegian Sea, the waters around Newfoundland and off many of the coasts of all the continents. The yield of coastal waters can be increased by fertilizing. This was shown, for instance, by an experiment in Scotland. An inland lock or bay of salt water with an area of about eighteen acres and an average depth of 2 meters was fertilized with so little as 600 pounds (272.2 Kg.) of sodium nitrate and 400 pounds (181.4 Kg.) of superphosphate. A neighboring lock received no fertilizer. There was an immediate rise in the vegetation of the fertilized lock to three to four times the original amount and the growth of fish leaped upward. Baby flounders grew in thirteen months to a size equal to that of two or three years' growth in the North Sea, itself a rich feeding ground.

We mentioned in our earlier paper the carp culture of German inland lakes. The fish farms of Central Europe produce as much as 500 pounds (226.8 Kg.) of fish per acre, which has been compared to the 200 pounds (90.7 Kg.) of beef or mutton obtainable from pasture land of quality. A bulletin of the Department of Agriculture explains how to manage farm fishponds for food production.

Soy Beans, Peanuts, Wheat Germ and Corn Germ.—Protein of relatively high biologic value is provided by beans and peas. Early in the emergency created by the war, production goals for soy beans were raised for

two important purposes, (1) for the oil to replace the diminishing supply of fat and (2) as a source of protein. The protein of soy beans is excellent with respect to all of the essential amino acids except cystine. The same, indeed, is true of common beans. But since wheat flour contains cystine, the use of beans with bread, or better still of baked beans and brown bread, provides a source of protein which is adequate. The vitamin values of the soy bean compare favorably with those of meat; the choline content is higher than that in leafy vegetable roots and grains. In the war soy bean flour that was free of fat found a ready outlet for some purposes, notably in doughnut manufacture. Its widespread household use, however, lagged far behind what had been desired. Milk made from soy beans has proved its usefulness especially for the feeding of children and invalids in regions of the world, especially in China, Thailand and India, where other milk is unavailable. A cookbook devoted entirely to the soy bean contains precise directions and a large group of recipes for using both the garden type of soy bean and the flour prepared from field beans.

The peanut crop was also much expanded in the war years. In this instance consumer acceptance was more satisfactory. Sherman has pointed out that beans, peas, peanuts and soy beans could assume a considerably larger part in the human diet with nutritional as well as agricultural advantage.

Wheat germ and corn germ customarily diverted to animal feeding by the millers of flour and degerminated corn meal represent a source of protein of high biologic quality that is of more importance than has been assumed. It is estimated that some 150,000,000 pounds (68,038,800 Kg.) of wheat germ and 600,000,000 pounds (272,155,000 Kg.) of corn germ might be made available for human consumption in this country. The total amount has been compared to the 500,000,000 pounds (226,796,000 Kg.) of skim milk powder produced in 1941.

Another source not only of a protein reputedly excellent in biologic quality but also of fat is the sunflower seed. The nutritive value of sunflower seed has long been recognized, especially in Russia, where great quantities are consumed. Sunflower grows in almost any soil and its cultivation might be increased with advantage in many countries.

Yeast.—An almost limitless potential source of protein of relatively high nutritive value is yeast. Mention was made of yeast in our earlier paper, but more information is now available because extensive effort was directed toward its development in the war years. Production of yeast for food was undertaken in this country, in Germany, in England, in Jamaica and in Puerto Rico. Food yeast was grown under primitive conditions and used apparently with great advantage in an internment camp in Java. Yeast requires sugar for its growth, likewise a source of nitrogen. For the latter, ammonia will suffice. In the camp in Java, a diastase was obtained by growing mold on corn and with this diastase sugar was produced from starch wastes such as old inedible potatoes. For the source of nitrogen, spoiled fish and spoiled meat were used, and when the amounts of these proved insufficient, ammonia was distilled from urine. The weekly yield of food yeast amounted to more than 60 Kg., an amount significant as a supplement to the meager diet provided by the Japanese. In Puerto Rico, surplus molasses was the culture medium, with urea obtained from sewage supplying the nitrogen. In Germany,

yeast was cultured on wood sugar in amounts said to have exceeded 100,000 tons a year.

The protein of yeast has been found to be deficient in the sulfur-containing amino acids methionine and cystine; however, methionine may not be required by man if his diet contains cystine. Cystine is contained in the protein of rice or wheat, and either rice or wheat flour usually constitutes a large part of the diets of people obtaining little animal protein. Deficiency of yeast in sulfur-containing amino acids, therefore, may not represent a serious disadvantage to the use of yeast. The studies in Puerto Rico supported the opinion that the protein of food yeast (*Torula*) is lower in biologic value and hence lower in net protein value than that of dried brewers' yeast, and yet as good as that of soy flour and much superior to that of navy beans, rolled oats, whole wheat flour and whole corn. A purified yeast protein obtained in Germany by treatment of yeast with alkali and subsequent precipitation with acid alcohol was found effective in maintaining nitrogen balance in experiments on man, white rats and hogs.

Approximately 10 per cent of the total nitrogen of yeast is nonprotein nitrogen, a relatively large part of which is present in the form of purines, and the effect of this when yeast is used in human nutrition appears not as yet to have been fully explored. Large daily doses (130 Gm.) increased the concentration of uric acid in the blood and urine. On the other hand, relatively smaller amounts did not have these effects. An amount of yeast as small as 10 Gm. daily, to judge from studies made by Sure with rats, may be of value as a supplement to the proteins of white flour or white rice. It is possible that further experiments will lead to the development of food yeasts which contain less purines. Numerous methods have been developed for incorporating yeast in breads, soups and other foods. The greatest need for food yeast would appear to be in India, in China and in the tropics where population pressure on the land or economic conditions or both are great enough to make impossible provision of enough meat and milk to supply the population with protein of high biologic quality. The cost of yeast is small, and addition of it in amounts not more than 3 per cent might help enormously when diets are strictly vegetarian.

Cultures of other micro-organisms may serve as protein food for man. *Fusarium lini* Bolley with a supplement of thiamine provided adequate amounts of the B complex vitamins for the normal growth, reproduction and lactation of mice. Fed to mice as the only source of protein at a 15 per cent protein level, growth was as satisfactory as with 18 per cent of casein. The possibilities as foods of this *Fusarium* and related molds appeared to Vinson and his colleagues to be important, for they can be easily grown in the course of the alcoholic fermentation of the 6 and 5 carbon atom sugars present in wood hydrolysates, sulfite waste liquors and silage.

FOODS FOR RELIEF

Foods best adapted for stockpiling or for shipping to areas in need of relief must be relatively imperishable and largely free from water. In the emergency of any war or major social turmoil, transportation at once becomes a problem of immense importance. Freight cars and ships in wartime are in great demand for moving troops and military stores, and the facilities that can be obtained for moving food are rarely ever adequate to meet requirements fully. Moreover, transportation is peculiarly sensitive to enemy attack. In-

Germany, near the war's end and later in the occupation period, collapse of transportation contributed as much or more to famine as did shortage of the total food supply. White flour, white rice, degerminated corn, sugar and fats and oils best meet requirements for stockpiling and shipping. They, however, for the most part are poor providers of minerals, vitamins and the better proteins. Among foods best suited to supply these factors are cheese, dried beans, dried peas and dehydrated (or for certain purposes canned) milk, eggs, meat and fish.

Canned food has played a role in every recent war, but never a greater one than in the war just passed. Its contribution to maintaining the nutrition both of the military and civilian populations of this country and of our allies was tremendous. Canned milk, canned meat, canned fish and great varieties of canned vegetables and fruits were shipped to all parts of the world in quantities as large as means of transportation would permit. From the standpoint of imperishability and good nutritional quality, foods preserved by modern canning methods rank among the best. They also lend themselves to stockpiling. Their only disadvantage is that their weight and bulkiness complicate their transportation.

Dehydration as a means of saving shipping space represented a major contribution in solving the problem of providing Britain with food enough to keep its people fed in World War II. In the years before the war about 3,000,000 tons of water were imported into Britain. This was contained in the food that came from overseas. Much of that wasted effort was overcome by shipping foods from which the water in large part had been removed. Eggs were dried. Before the war British imports included 2,000,000,000 eggs, of which 75 per cent (or 100,000 tons) was water. Fresh meat for transport overseas called for refrigerated ships, whereas dried meats could go in any kind of boat. Dried soups were shipped in quantity. Cheese and butterfat were in great demand as shipping items, since they were relatively free of water. Powdered egg was produced and shipped in enormous quantities. It proved unsatisfactory until methods were developed which insured good solubility. With the better products which eventually were provided, omelets, cakes and custards could be made which equalled those prepared with fresh eggs. However, the most important items in this category were evaporated milk and dried skim milk.

Milk.—Wherever liquid milk can be obtained it represents a most acceptable and satisfactory means for obtaining protein of high biologic quality. Goat's milk possesses about the same nutritive properties as cow's milk, but goats can thrive in rocky country where cows do poorly. In such places raising goats for local consumption of their milk and meat has been encouraged. Fluid milk, however, because of bulk and perishability, is expensive to transport to distant regions. The handicap is largely overcome by processing before shipment. Evaporated milk, dried milk and many forms of cheese are relatively imperishable, occupy relatively little shipping space and compared to fluid milk can be delivered to a distant market at a relatively low cost.

Dry milk, either dry whole milk or dry skim milk, has come to play a part of great importance in feeding undernourished people. Its value in the treatment of the famished inmates of Nazi concentration camps was discussed by Pollack. It is excellently suited for constructing diets high in protein. For this purpose it can be mixed with other foods in large proportions or

made into a paste by adding 1 part of dry milk powder to 2 parts of water. Whole liquid milk or buttermilk or orange juice may be used as the diluent. Flavoring can be added if desired, and added egg or powdered egg gives the mixture a custard character with additional nutritional advantages. With these products now becoming available there is little need for any of the various protein concentrates of fancy composition appearing in the drug trade or for the protein hydrolysates which recently have been promoted for oral use. There is little evidence that any of these products are absorbed more readily than milk even when digestion is impaired. Their cost is out of sight and the atrocious palatability of protein hydrolysates makes them unacceptable even when administered by stomach tube.

Among milk products of great usefulness as a source of protein in the war was cheese, which rivals any food available as a source of protein, is relatively imperishable and lends itself to shipping. Very large amounts of American cheddar cheese have been exported and production in this country has increased accordingly. American or cheddar cheese has represented about 80 per cent of a total cheese production, which now is said to utilize annually about 10,000,000,000 pounds of milk. An economic as well as dietary objection to converting milk to cheese is the loss of whey, which contains the lactalbumin of the milk, some of its mineral and much of its vitamin content. Uses for whey have been difficult to develop, and to waste this highly nutritious material is well-nigh criminal. Whey can be dried to powder and used advantageously in bread making much as has been done with dry skim milk. It also can be used in candy manufacture, but other outlets ought to be explored.

FATS AND OILS

A major problem in all the war-torn countries, and not without real significance in North America, was the shortage of fats occasioned by the war. This developed from two causes: (1) the interruption of imports of coconut, palm and other oils from the Pacific islands, and (2) the demand for oil and fat for war use.

While the evidence for a minimal fat requirement is inconclusive, the opinion prevails that 20 to 25 per cent of the total calories should come from fat. Half of this total usually should be obtained in a visible form as butter, lard and oil. The total would amount to from 54 to 68 pounds (24.5 to 30.8 Kg.) per year, whereas the per capita prewar consumption in the United States was 93 pounds (42.2 Kg.). The principal sources of invisible fat are dairy products other than butter, meat, nuts and eggs. The supply of them as well as the supply of fats and oils has been short in Europe since the war began. Much could have been done to alleviate postwar shortage of fat in Europe had the United States adopted a more enlightened program for its use of fats and oils during the war years. Because of their relative imperishability fats and oils can be stockpiled over years. However, such a program involved restriction of the use of fat for soap and for military purposes, and resistance was strong enough to prevent any such restrictions.

FOOD MANAGEMENT

The successful prosecution of World War II depended to a large extent on the herculean efforts of farmers and other food producers in the United States and Canada. Blessed by successive years of better than average growing weather, food production was increased almost a third and much of the increase became available for

export. A further vital contribution involved measures that were introduced for managing distribution, "set-asides" of food commodities, price control and differential rationing. This is not the place for discussion of food management over the world. In due time the story will be told by the Food Research Institute of Stanford University, which has received a large grant of money from the Rockefeller Foundation for a five year study of the subject. Some account of procedure in the United States has been given by Hendrickson and by Clayton and Black. An account of procedure in Canada has been published under the authority of the Minister of National Health and Welfare. The experience of Switzerland has been reported in a recent monograph by Fleisch, and separately under the auspices of the Food Research Institute by Rosen.

By careful management of their food supplies the Swiss and British came through the war without deterioration, and indeed in many respects with actual improvement of the public health. Sir William Jameson, British Minister of Health, could state in 1946 that infant mortality rates and puerperal death rates had fallen steadily. The problem of nutrition in Great Britain received interesting consideration in a recent book by Cruickshank. In Switzerland, despite lowering of food supplies and shortages of protein and fat, the heights and weights of children were maintained. The incidence of most reportable infectious diseases was diminished, as was that of diseases of the gastrointestinal tract, including appendicitis.

SUMMARY AND CONCLUSIONS

For populations in the path and in the wake of war, finding food becomes a matter of supreme importance. By utilizing edibles which in normal times are disregarded, much can be done to alleviate or postpone the worst effects of famine. Substantial contributions to the family larder can be made by gardening. By these means sufficient vitamins and minerals are usually obtainable. The pressing problems, then, relate to calories and biologically superior protein. Cereal grains, wheat, corn, barley, oats and rye are efficient providers of calories and possess the advantage of being readily transportable. However, the proteins of cereals and vegetables fail to provide all the amino acids necessary; moreover, a need for fat, which apparently is very real, cannot be met with cereals and vegetables alone. Therefore, planning to meet the food needs of countries overrun by war, likewise to meet the needs of areas like India where population pressure excludes the use of land for producing meat and milk, involves attention to supplies of protein and fat. Certain resources, especially fish, can be made to contribute more abundantly. Food yeast offers possibilities. Yeast and beans, soy beans in particular, afford proteins which when taken with wheat flour or white rice are reasonably complete. Fat production can be augmented by increased planting of "oil seeds" such as soy beans, peanuts, rape and okra, and fat can be diverted from other uses in order to increase the amount available for food. Foods for distant shipping in conditions of emergency, likewise foods which lend themselves to stockpiling, must be low in water content and relatively imperishable. White flour, white rice, sugar and fats and oils best meet such requirements. They, however, for the most part are poor in minerals, vitamins and superior proteins. Among the foods best suited to supply these factors in emergencies are dehydrated milk, cheese, dried eggs and fish.

Clinical Notes, Suggestions and New Instruments

GRANULOMA INGUINALE OF THE VAGINA AND CERVIX UTERI WITH BONE METASTASES

HENRY PACKER, M.D.
HENRY B. TURNER, M.D.
and
A. D. DULANEY, Ph.D.
Memphis, Tenn.

Since McLeod's description in 1882 of granuloma inguinale as a "serpiginous or lupoid ulceration of the genitalia," this disease has been more clearly differentiated from other granulomatous lesions of the genitalia and the vagaries of its clinical manifestations have received increasing attention. Earlier concepts of the progress of this infection solely by serpiginous spread or by autoinoculation have been broadened in recent years as a result of accumulated evidence of lymphatic spread and involvement.¹ Examples of the latter are the inguinal "pseudobubo" ^{1a} following the primary genital lesion, the demonstration of the Donovan bodies in regional lymph nodes ^{1a, b} and the elephantiasis of the genitalia ² which may occur in this disease. To lymphatic spread has also been attributed the extensive involvement of the pelvic organs following granuloma inguinale of the cervix and vagina.³ Of significance are the pronounced systemic manifestations which are frequently associated with lesions in this region, particularly when complicated by pregnancy.⁴ These systemic manifestations indicate that granuloma inguinale, far from being strictly a local disease of the genitalia, has potentialities for widespread dissemination throughout the body, either of the specific etiologic agent or the products of secondary invaders. The former possibility has already been demonstrated by a few reported cases of metastatic lesions of bones and joints in distant parts of the body following lesions of the genitalia.⁵ Thus has evolved from the early beliefs of the limited implications of this disease a clearer understanding of the possibilities for widespread dissemination which this disease possesses.

The case of granuloma inguinale to be reported is of interest in view of the simulation of a carcinoma of the cervix, the profound systemic manifestations, the metastatic bone lesions and subcutaneous abscesses at a distance from the site of the primary lesion and the demonstration of organisms having the morphology of Donovan bodies in blood culture.

REPORT OF A CASE

A Negro woman, aged 19, was admitted to the maternity service of John Gaston Hospital Feb. 21, 1946, with a tentative diagnosis of threatened abortion and with evidence of pneumonia of the upper lobe of the right lung, which was later confirmed

From the Divisions of Preventive Medicine, Obstetrics and Gynecology, and Pathology and Bacteriology, University of Tennessee College of Medicine.

by roentgen observations. Subsequently she admitted having passed some "flesh" from the vagina the day before entering the hospital, so that it is likely that a complete or incomplete abortion had occurred before admission. She responded well to sulfadiazine therapy and was discharged in afebrile condition from the hospital on the ninth day.

She returned to her work in a restaurant and worked for one week. She was obliged to discontinue work at this time because her left hip had become painful and swollen so that she was unable to walk. She also had some discomfort in the right lower quadrant of the abdomen and in the back at this time.

During the next seven months she was confined to her home at a result of these complaints, spending most of her time in bed. She had no menstrual periods, and lost 60 pounds (27.2 Kg.) in weight (from 150 pounds [68 Kg.]) over this period. She was seen in the outpatient department in July, and at that time a woody induration of the left anterior wall of the vaginal vault was noted, with no involvement of the cervix. A diagnosis of streptococcal infection of the vagina and adnexa was made.

Four weeks before her second admission to the hospital she began passing bloody urine containing clots, accompanied by dysuria. The pain in the lower part of the abdomen became more severe at this time, and she also noted a bloody vaginal discharge.

She was admitted to the hospital for the second time on October 6. On admission her temperature was 102.4 F., pulse rate 100 and respiration rate 26. Blood pressure was 100 systolic and 60 diastolic. She was rather emaciated and appeared to be weak. Among the significant findings at this time were tenderness in the lower abdominal quadrants and the presence of a tender, nodular, friable infiltration of the cervix and lateral and posterior walls of the vagina. Bimanual examination was unsuccessful because of the extreme tenderness and the "frozen" condition of the pelvic organs due to parametrial and adnexal thickening. Rectal examination also produced excruciating pain.

Laboratory examination on admission revealed a red blood cell count of 3,700,000 per cubic millimeter, a hemoglobin level of 10.0 Gm. per hundred cubic centimeters and a white blood cell count of 20,250 per cubic millimeter with 84 per cent polymorphonuclear leukocytes. The corrected sedimentation rate was 31.5 mm. in sixty minutes. The urine showed albumin

of sanguinous pus. Soon after this she complained of pain in the right knee and in the knuckle of the left hand. No swelling was noted, and the pain soon subsided. Two weeks later the pain recurred in the same regions, this time being associated with definite swelling and local tenderness. Again these signs and symptoms subsided, only to recur two weeks later, progressing this time to form large fluctuating abscesses beneath the skin, which appeared normal. These abscesses were incised.

Fig. 2.—Pathognomonic cell of granuloma inguinale, obtained from abscess of the hand. The macrophage cell contains a cyst or "nest" of closely packed Donovan bodies. In the cytoplasm of the macrophage cell individual Donovan bodies show the typical encapsulated, safety pin forms.

Fig. 1.—Bone changes underlying subcutaneous abscesses. The distal end of the second metacarpal bone shows rarefaction with extensive periosteal proliferation. The tibia shows an area of rarefaction on the medial surface of the condyle.

(3 plus) with innumerable white and red blood cells. The Kahn test report was 3 plus. Frei, Ducrey and tuberculin cutaneous tests were negative in result. A roentgenogram of the chest revealed no abnormality. Two routine blood cultures and routine agglutination tests were also negative in result.

Soon after her admission to the hospital, a perirectal abscess developed, which was incised and drained, with the evacuation

The pus was cultured by routine procedures, but nothing could be grown. Tender swellings of the dorsum of the right hand and of the left elbow also appeared at this time, but did not progress to suppuration. Roentgenologic examination of these areas revealed areas of bone destruction under each swelling noted before. The right tibia showed an area of destruction 2 cm. in diameter on the medial surface of the condyle. This area of necrosis was surrounded by a rim of sclerosis. In the distal end of the shaft of the second metacarpal bone of the left hand was a cystlike area of rarefaction with extensive periosteal proliferation (fig. 1). The navicular bone of the right hand showed an area of destruction involving one half of this bone.

A cystoscopic examination was performed because of the urinary complaints present at the time of admission. This revealed a granulomatous lesion of the bladder, involving the floor and left wall. There was some obstruction of the left ureteral orifice, with hydronephrosis and hydronephrosis on that side. The impression was that of an extensive malignant growth, originating from the cervix uteri and spreading to involve the bladder.

Biopsies of the cervix uteri revealed numerous large macrophages, suggesting the possibility of granuloma inguinale. Intensive search for the Donovan bodies revealed them in the hematoxylin and eosin preparations, although they appeared rather pale and were seen only with difficulty in these preparations. Preparations stained with Giemsa or with Dieterle's silver stain demonstrated the Donovan bodies more clearly. What we considered to be the most satisfactory preparation of all in demonstrating the Donovan bodies was obtained by simply smearing a particle of granulation tissue on a slide and staining by Wright's technic, as for blood smears. Contact smears of the granulation tissue at the sites of the incisions

of the left hand and right knee stained by the latter procedure also revealed these organisms in profusion in macrophage cells (fig. 2).

A blood culture employing tryptose-peptone-egg yolk agar showed organisms morphologically resembling Donovan bodies. This, together with observations made with an antigen obtained from pus from one of the abscesses, is being reported separately.⁶

Response to intravenous injections of antimony potassium tartrate was dramatic. The initial dose was 3 cc. of a 1 per cent solution. Subsequently the dose was given every other day, increased by 1 cc. each time until the tolerance level of 8 cc. was reached. Within a week the temperature receded to normal, appetite improved and weight gain was noted. During the next three weeks a gain of 20 pounds (9.1 Kg.) in weight was made. The granulation tissue in the vagina became firm in consistency and shrank in size so that only a small area of the cervix was involved. Granulation tissue at the site of the incisions in the hand and knee healed more slowly, and Donovan bodies could be demonstrated in this granulation tissue twenty-four days after treatment was initiated. Forty days after treatment was started the typical encapsulated Donovan bodies were no longer observed, but in a few macrophages there could still be seen clumps of nonencapsulated organisms, similar in appearance to Donovan bodies. The patient was discharged from the hospital with advice to continue her treatment in the outpatient department.

COMMENT

This case is of interest from the standpoint of providing additional evidence of the capacity for widespread systemic invasion inherent in granuloma inguinale of the cervix uteri. While bone metastases as described in this case have rarely been reported in the literature, it is conceivable that they have occurred more frequently than has been recognized and that they have been mistaken for cancers of the cervix with bone metastases. The possibility of confusing, on clinical appearance, granuloma inguinale of the cervix with a malignant growth of that site can readily be understood, as it is doubtful whether these can be distinguished on clinical grounds alone. What cannot be condoned is the treatment of such cases as cases of malignant growths without substantiating histologic findings, on the grounds that the biopsy may not have been correctly taken and that the clinical evidence of cancer was so overwhelming.

Attention should be called to the fact that in biopsy material the possibility of granuloma inguinale should be suspected when large numbers of large macrophages are present. The diagnosis can then be verified by the careful study of tissues for the presence of the Donovan bodies. Since these bodies are most readily seen in contact smears stained by the Wright technic it is always advisable to supplement the biopsy study with this procedure when feasible. This is especially indicated when lesions of the cervix suspected of being malignant fail to reveal evidence of being so on biopsy study.

The dissemination of the infection, with systemic manifestations, which occurred in our patient after an abortion emphasizes the hazard which pregnancy holds for patients with granuloma inguinale of the cervix. This hazard has been emphasized by others,¹⁴ who have reported widespread pelvic involvement and death following such a complication. The importance of having a high index of suspicion for granuloma inguinale in the presence of lesions of the cervix in pregnant women is obvious.

The occurrence of bone lesions in this patient at sites commonly involved in hematogenous spread of infection justifies the assumption of hematogenous dissemination of the etiologic agent. In no instance was there any evidence of involvement of the skin at the site of the fluctuating abscesses prior to their incision. This rules out the possibility that autoinoculation played a role in producing these lesions at a distance from the original site of involvement. The failure to demonstrate common organisms by routine blood culture and the demonstration in blood culture of organisms having the morphologic appearance of Donovan bodies would appear to confirm this opinion. We were unable to find any other instance reported in the literature

in which Donovan bodies have been observed in blood culture. Failure to observe continued growth in the medium employed indicates that this medium is not a suitable one for the continued propagation of this organism.

SUMMARY

A case of granuloma inguinale is described in which the initial involvement of the vagina, cervix and bladder was subsequently followed by bone metastases with overlying abscesses in distant parts of the body.

The progress of the infection, with profound systemic manifestations, following an abortion emphasizes the hazard of pregnancy for women with untreated granuloma inguinale of the cervix.

The sites of bone involvement and the deep tissue suppuration arising therefrom suggest hematogenous spread of the etiologic agent in this case. The demonstration, the first which we have been able to find in the literature, of organisms having the morphologic appearance of Donovan bodies in blood culture on special medium substantiates this impression.

The unreliability of routine hematoxylin and eosin preparations of biopsy material in demonstrating clearly the Donovan bodies is pointed out.

Attention is called to the fact that granuloma inguinale of the cervix uteri may simulate a carcinoma in appearance. It is recommended that in the examination of lesions from the vagina and cervix for suspected malignancy smears be obtained from the surface of the lesion, or from particles of granulation tissue, and stained with Wright's stain. This rapid simple procedure might well be placed on a routine basis in population groups in which granuloma inguinale is known to occur.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

CHORIONIC GONADOTROPIN (See New and Nonofficial Remedies, 1947, p. 374).

The following additional dosage form has been accepted:

GEORGE A. BREON & CO., KANSAS CITY, MO.

Chorionic Gonadotropin, 5,000 International Units and 10,000 International Units: 10 cc. vials. A powdered preparation which, when diluted with the accompanying 10 cc. vial of sterile distilled water containing 0.2 per cent metacresol, provides a solution having a potency of 100 or 500 international units, respectively, per cubic centimeter.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1947, p. 462).

The following dosage form has been accepted:

PITMAN-MOORE COMPANY, INDIANAPOLIS

Typhoid Vaccine: 5 cc. and 20 cc. vials. Each 1 cc. contains 1,000 million killed typhoid bacilli (Panama carrier strain 58). Preserved with sodium ethyl mercuri thiosalicylate 1:10,000.

STERILE SULFADIAZINE SODIUM (See New and Nonofficial Remedies, 1947, p. 141).

The following dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Sulfadiazine Sodium (Sterile Powder): 5 Gm. ampuls.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1947, p. 214).

The following dosage form has been accepted:

THE S. E. MASSENGILL COMPANY, BRISTOL, TENN.

Solution Ephedrine Sulfate, 3 per Cent: 473 cc., 120 cc. and 30 cc. bottles. Preserved with 0.5 per cent chlorobutanol.

WHEAT AND WORLD HUNGER

Why do we send wheat as a most important article of diet to the hungry people we are trying to help? The high food value of wheat per unit of weight, its excellent keeping qualities, its ease of handling and storing make it ideal for shipping; further, wheat satisfies hunger as do few other foods. Why is wheat the dominant food grain—the grain of choice for bread? The answer rests chiefly in two factors: (1) properties inherent in wheat itself and (2) the widespread, general insistence on wheat and its milled products.

Aside from certain areas of Monsoon Asia where agricultural factors and habits observed for centuries have combined to establish rice as the dominant food grain,¹ five cereal grains—wheat, corn, oats, barley and rye—constitute the principal grain crops. Except for certain differences in quantitative aspects, all cereal grains exhibit similarities in composition and nutritive value. Some of these quantitative differences, however, are not without significance; for instance, the association of pellagra with the consumption of high proportions of whole ground cornmeal.

Wheat, among the five principal grains grown in Western countries, embodies most of the superior qualities of each of these common grains. It is not bulky, thereby minimizing the costs of handling; as whole grain or white flour it has excellent keeping qualities; by virtue of the rather unique quality of its protein (gluten), wheat flour is preeminently suited for making yeast-leavened breads.

The present shortage of wheat concerns physicians throughout the world because it stands as a stark barrier to the relief of world hunger and as an obstacle to world economic recovery. Never before has relief from hunger of so many millions of persons been so contingent on available supplies of a single food item.

Why is there a world wheat shortage? In spite of the devastations of World War II, the Western countries of Europe demonstrated remarkable powers of recovery in wheat production in 1946. The reverse in this trend in 1947 was caused principally by unfavora-

ble weather conditions for growing wheat in several Western and Southern European countries. Wheat reserves in recent years have been absent in practically every country that normally produces a surplus of the grain.

The principal non-European wheat-exporting countries include Australia, Argentina, Canada and the United States. Australia's wheat exports, although important, are relatively small; Argentina's wheat exports are under government monopoly, with insistence on payment in American money at the highest price of wheat on the world market; Canada's exports are destined largely for Great Britain. This leaves the United States to fill the gap as far as possible. In those countries where the demand for wheat imports has not been satisfied, the strain on other available food supplies has been stretched to the limit; demand for food has overwhelmed supply; food prices have skyrocketed except where controlled; black markets in foods tend to flourish so that whole national economies are disrupted by present food shortages.

Why not spread the strain to other grains or to other foods than wheat? Few countries produce surpluses of any food. In Western Europe many countries are deficient in several staple foods. The use of fruits and vegetables is largely precluded in the relief of mass hunger by their bulk, high water content, easy spoilage, inflated prices and high cost of transport by rail and water. Some dehydrated foods are being sent to Europe, but the quantities available are not significant. Small amounts of meat, dehydrated eggs and milk are also being sent to European countries. However, all profitable and large scale production of top quality meat, dairy or poultry products requires grain. Shortage of feed grains, such as now exists in this country, should tend to be balanced by appropriate reductions in live stock. There is no escape from the fact that cereal grains (food or feed grains) used directly and indirectly as food are the bulwark of sustenance for most of the world's human population. The excessive production of animal-converted foods—especially top quality meats which require extra grain for fattening—is a waste of food calories during a world food crisis. Less expensive cuts of meat contain relatively more protein per unit of weight, are equally nutritious and require much less grain in their production.

In the forthcoming edition of the "Handbook of Nutrition" of the Council on Foods and Nutrition other aspects of the problem of the relation of wheat to human nutrition will be discussed. Some of the chapters will appear first as special articles in THE JOURNAL. Maynard of Cornell will describe the contribution of foods of plant origin to the human diet, Ancel Keys will discuss starvation and Wilder and T. E. Keys (this issue, p. 322) the role of foods for emergencies. Now more than ever before a knowledge of nutrition is significant not only for individual health but for the future of the world.

¹ Millet and buckwheat (not properly a cereal grain) continue in general use in a few regions.

GENETIC CONTROL OF LYMPHOMATOSIS IN THE FOWL

Neoplastic diseases are not exclusively a problem in man; lymphomatosis in fowl causes an annual loss in this country of \$50,000,000.¹ Forty per cent of the high mortality in growing fowl during the first year of life results from lymphomatosis. The disease is characterized by a proliferation of undifferentiated lymphocytes in the viscera, nerves and iris; it is transmitted to fowl under 5 months of age by contact with older stock. Since lymphomatosis is transmissible by cell-free filtrates it is presumably a virus disease, neoplastic in character.

Hutt and Cole² controlled the disease by genetic methods. In twelve years they developed from a previously unselected population two strains of fowl resistant to the disease. Other desirable features such as satisfactory body size, egg size, and egg production were not lost in the process. Simultaneously, by the same genetic methods, a strain highly susceptible to lymphomatosis was produced, despite the fact that selection was less efficient. In the resistant strains mortality from the neoplasms was reduced to about one third its original figure; in the susceptible strain it was doubled. The latter strain now has a tumor mortality of over four times that of the resistant strains under identical conditions of exposure.

Records of breeding were kept, including the ancestry of each chick; uniform environment was maintained and equal natural exposure to lymphomatosis was insured. The sires and dams whose production of the most resistant families had been proved were selected for breeding. Not only was mortality from lymphomatosis reduced but that from other causes as well. Decreased mortality from lymphomatosis was accompanied by an increase in average age at which the disease appeared.

After the desired lymphomatosis-resistant stock was developed, the next problem concerned utilization of the fowl to best advantage. The investigators concluded that the best method would be to send the desirable genes of the resistant strains in thousands of cockerels to head flocks that supply the hatcheries that now produce about 90 per cent of the country's chicks.

While this method of attack on a problem in neoplastic disease is interesting, similar genetic methods are not, in the present state of society or in the near future, applicable to problems in human disease. Furthermore, there is no known human neoplastic disease comparable to this form of lymphomatosis in fowl. The human malignant lymphomas have to date revealed no transmission by contact, transmission by

cell-free filtrates or high incidence in certain families. In these respects the lymphomatosis of fowl resembles an infectious disease and the methods used in its control were those applicable to some infectious diseases of animals but not to those of man.

THE PAPANICOLAOU TEST FOR UTERINE CANCER

Early diagnosis of uterine cancer has depended chiefly on the subjective symptoms of the disease. Often the disease is far advanced by the time the patient becomes sufficiently aware of discomfort to seek help. Study of the normal and abnormal variations in the vaginal smear in guinea pigs and in women convinced Papanicolaou that carcinoma of the fundus of the uterus and carcinoma of the cervix are to some extent exfoliative lesions. Cells at the free surface of the growth tend to become dislodged and subsequently to find their way into the vagina. Papanicolaou developed a method for collecting the cellular debris, which is smeared on glass slides and specifically stained so that the various components may be studied. In their first report on the method, Papanicolaou and Traut¹ emphasized that "whereas the method makes the material for examination easily and frequently obtainable at low cost, the interpretation of the smear requires the services of a careful and discriminating cytologist who has had experience in this field. Few persons can be depended on for this work at the present time."

Cervical cancer is revealed in vaginal smears by the appearance of characteristic cells derived from the superficial layers of the tumor, which undergoes continual desquamation. These cells show great variety in form and size, much greater than that seen in sections of the tumor. The most characteristic feature of the abnormal cells is the atypical form and structure of their nuclei and vacuolization of the cytoplasm. A commonly found, characteristic cell type is an extremely elongated one resembling a smooth muscle fiber. Erythrocytes are generally found in large numbers. Papanicolaou and Traut, utilizing the vaginal smear technic, failed to detect malignant cells in 4 of a total of 127 patients with demonstrable cancer of the cervix. They found cancer cells in the vaginal smears of 46 of 53 patients with cancer of the fundus.

Meigs and his associates² reported 4 positive smears in a total of 153 negative cases, an error of 2.6 per cent. Of 46 patients with proved cancer of the cervix, positive vaginal smear diagnosis was made in 45, an error of 2.2 per cent. These authors expressed their belief that a cancer cell can be more readily identified in the vaginal smear than in body fluid sediments or sputum. This increased accuracy in diagnosis is proba-

bly due to the fact that cells of the vaginal fluid are in greater concentration and have suffered less degeneration. These authors did not feel justified in advising operation for uterine cancer solely on the evidence of a positive vaginal smear. They insisted that the positive smears should be confirmed by biopsy or curettage. They also emphasized the need for a systematic study of the entire smear and an experienced knowledge of cytology. The method of vaginal smear examination, in their opinion, is an important addition to the early recognition of uterine cancer.

Block³ has warned that a positive diagnosis from a vaginal smear does not indicate immediate radical intervention or irradiation, but rather that confirmatory biopsies of the cervix or endometrium should be performed.

Scheffey and Rakoff⁴ deplore in a recent communication the exaggerated statement that appeared in the Sept. 19, 1947 issue of the *New York Times* regarding the cytologic test for uterine cancer. "The message of hope" reported in this article was condensed from an article by Clive Howard in the October 1947 issue of the *Woman's Home Companion*. According to this article "the new method is inexpensive, painless and at least 97 per cent accurate. If put into general use it may almost wipe out this form of cancer." The danger was the creation of a tendency to depend on a laboratory examination rather than on a complete study of the condition. The report does not stress that a positive smear must be confirmed by cervical biopsy or resection and/or by curettage of the uterine cavity. The article was completely laudatory except for mention of the 3 per cent error of the investigators. Scheffey and Rakoff found in a study of 500 consecutive cases, taking only a single smear and without clinical knowledge of the cases on the part of the cytologist, that of 63 proved cancer patients correct positive smears were obtained in 44, or 70 per cent. In other words, 30 per cent of the cancer cases were missed. Excellent correlation, however, was obtained in 437 patients who did not have carcinoma, correct smears being obtained in 430, or 98.4 per cent, while false positives occurred in only 7, or 1.6 per cent. Apparently, therefore, the good results for the entire group, namely 98.4 per cent correct results, were influenced largely by the high proportion of negative patients. In studies by other workers false positives were comparatively rare but positive cases were missed in an appreciable proportion of the cases. The limitations of the vaginal smear method, especially when only one smear is taken, are obvious.

Recently a manufacturer of laboratory equipment has promoted the sale of the materials for the Papanicolaou test together with a hundred slides of various types of cells found in cervical smears. The firm cannot, however, sell the most important ingredient—a compe-

tent pathologist to study the specimen promptly after it is secured from the patient. The offer implies that special training is not necessary to secure and to examine the specimen. The indiscriminate use of this test will result in more harm than good.

Current Comment

CHECKING THE SPREAD OF YAWS ON PACIFIC ISLANDS

On the numerous small islands in the Pacific Ocean within a few hundred miles of the atoll of Truk, thousands of the inhabitants are afflicted with yaws, an infectious disease caused by the *Treponema pertenuis* (*Spirochaeta pertenuis*) and resembling syphilis in some of its manifestations. The people on these islands now receive medical care by U. S. Navy personnel¹ from the Truk atoll; a medical team visits them every six weeks. The lack of personnel and ships and the distances led the navy physicians to try a single intramuscular injection of 200,000 units of sodium penicillin in 4 cc. of sterile water as a stopgap measure to check the spread of yaws. As it became available toward the end of the program, a single injection of 300,000 units of calcium penicillin in 1 cc. of beeswax and peanut oil was substituted. The persons treated numbered about 5,000. The careful records kept for the period from October 1946 to June 30, 1947 show that the rate of infection with yaws has been much reduced. The thirteen small islands south and east of Truk showed a reduction, over a period of six months, from 57 new cases per thousand per month to 16 new cases per thousand per month. The total number of clinically active cases was also reduced. At the same time the character of the lesions commonly present in those afflicted has changed. When this program began in 1946, the ratio between the open cases, with ulcers, and the closed cases was about one to two. In June 1947 the major portion of the total number of cases still active was of the "crab yaws" variety, the less infectious type. Since last July the islands south and east of Truk have been staffed with native health aides trained to give oxophenarsine hydrochloride ("mapharsen") and bismuth compounds and thus carry on curative treatment. Curative therapy with penicillin, which would be more satisfactory, cannot be instituted because of the lack of refrigeration facilities on the islands. However, the single massive dose therapy with penicillin will be continued on the islands north and west of Truk until they too can be staffed with natives trained in the application of curative therapy. Thus it appears that a single intramuscular injection of a massive dose of penicillin is effective in checking the spread of yaws and in controlling the active cases until curative therapy can be instituted. The U. S. Navy is to be congratulated on its effort to prevent the spread of a deforming and disabling infectious disease, which is particularly prevalent among members of the dark races of the tropics.

ORGANIZATION SECTION

Official Notes

HOTEL RESERVATIONS FOR THE ANNUAL SESSION IN CHICAGO, JUNE 21-25, 1948

A list of hotels in Chicago and information concerning the best way to secure hotel reservations for the Annual Session, to be held in Chicago June 21-25, 1948, may be found on advertising pages 56 and 57 of this issue of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. The meetings of most of the sections will be held on Navy Pier.

It is urged that physicians expecting to attend the annual session in Chicago fill in the application form to be found on the advertising pages indicated, sending it to Dr. Fred H. Muller, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, 195 West Madison Street, Chicago 2.

Medical Economics

THE SELLING PRICE OF A MEDICAL PRACTICE

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

Some time during his professional career, a physician may face the problem of buying or selling a practice. After the physician completes his internship or residency, he may consider purchasing the practice of an older physician. After establishing himself in private practice, he may for various reasons contemplate a change of location, involving both the sale of his own practice and the purchase of another elsewhere. Following the retirement or death of a physician the sale or disposal of his practice may be considered.

The sale or purchase of a medical practice raises many questions; a considerable number of requests for information and advice are received at the headquarters of the American Medical Association. Perhaps the most frequent question concerns the means of establishing a proper selling price for a practice. But little has been published on this subject recently. Thoroughgoing studies have not been made of either the economic or legal aspects; nor have there been any compilations of actual experiences. The Bureau of Medical Economic Research recently conducted an informal survey among secretaries of state medical societies and accumulated available facts from other sources.

SALE OF PRACTICES IN ENGLAND

In England the custom of selling medical practices for prices significantly above the value of equipment, supplies and other tangibles has long prevailed. A special circumstance exists in England and possibly in other countries where panel practices have been established as a result of the operations of sickness insurance systems. The following brief description of this custom was received in a communication from an authoritative source in London:

The sale of the goodwill of general medical practices in England is based on a figure related to the past earnings of the practice and to the estimated receipts from continuing patients. In all cases the gross earnings for one year (or the average gross earnings for two or three consecutive years) is taken as the basic figure from which to work. This figure is multiplied by the number of years' purchase agreed between the vendor and the purchaser. In the years preceding the outbreak of war in 1939 this factor varied between one year and two and a half years, the lowest figure being that obtainable in the least satisfactory circumstances such as the death of a man in singlehanded practice where there was no opportunity for the newcomer to be given any introduction to the patients.

The price increased directly with the degree of probability of transfer of the patients of the vendor to his successor. Experience has shown that state patients on the doctors' Panel Lists only infrequently exercised their right to transfer to another doctor rather than accept the services of the purchaser of their former doctor's practice. In consequence practices with a high proportion of state patients tended to change hands for slightly more than ones in which there was less certainty of the continued adherence of private patients.

On the average, a well established practice, where there was good opportunity to introduce a new partner, sold at about two years' purchase.

Another correspondent reported that this custom applies basically to general practices, although the goodwill of ophthalmic and radiologic specialists also may be sold. Unpaid bills may or may not be included in these transactions. In addition, it is usual to make a separate valuation of the "capital" of the practice, which would include drugs, supplies and equipment. This writer emphasized that it is not patients but goodwill that is sold.

AVAILABLE INFORMATION AND SUGGESTIONS

Current information concerning physicians' practices which are for sale may be obtained from several sources. A few state societies reported that they occasionally provide clearing-house facilities between parties; possibly most other societies would be willing to furnish available information. The medical journals are probably the most important source for such opportunities—including the classified advertising sections of local, state and national publications. Other avenues of approach for either the buyer or seller are medical placement agencies and inquiries among professional acquaintances. In addition, a physician wishing to purchase a practice may offer an advertisement.

Many of the secretaries of medical societies commented on the factors to be evaluated in ascertaining the selling price of a practice: Most of them considered that the tangible goods could be appraised readily but suggested that pricing of intangibles was extremely hazardous. The following is a list of types of goods, together with comments and suggestions, developed from available sources:

1. *Real and Personal Property and Equipment.*—Medical equipment, supplies and the physician's residence (if this is included) may be appraised by real estate brokers, equipment dealers and other consultants in order to establish a fair market value. Most authorities felt that these constituted the basic, if not the only value, of a medical practice.

2. *Transferable Contract Appointments.*—If the seller holds appointments as an industrial consultant or house physician, or holds other positions providing a salary or other regular remuneration, the possibility of transferring these to the buyer may be explored. A value equal to an agreed percentage, perhaps of the annual income for the first year, may be established for this assured income.

3. *Lease of Office Space and Residence.*—While housing and office space continue to be in short supply in many parts of the country, a money value may be established for the transfer of leases on desirable space of this nature.

4. *Uncollected Bills.*—Bills for current services to patients or for relatively recent services may be transferred to the new physician for some consideration, or other arrangements for collections may be made which will be mutually agreeable. Often, the selling physician or his heirs will retain them for collection through their own agents.

5. *Goodwill.*—A formula or procedure has not been suggested which might be used consistently to establish a cash value for goodwill. One secretary commented, "I am of the personal opinion that it is absolutely impossible for a physician to set a price on goodwill or the value of a practice as such." Another stated, "It depends to a great extent on the value of services,

character and personality. One doctor may not be able to give the same services as the previous physician, or to pick up and use the goodwill left behind because of difference in personalities or other intangibles, and thus may lose all the goodwill." The general conclusion was that since the personal element is so important in the services provided by a physician, it may not be valid to assume that a physician's goodwill can be sold in the same fashion as a manufacturer's or a retail store's goodwill.

6. Patients' Records.—The problem of evaluating patients' records as to goodwill is even more difficult. Case histories, diagnostic reports, financial and other records can be of great value in assisting a new physician in the treatment of patients of the former physician. Many secretaries, however, felt that patients' records were essentially intangibles and therefore difficult to price. In addition, one secretary pointed out that ethical and legal issues are involved in transferring such records to a buyer without the patients' consent. To some extent this objection may be overcome if arrangements are made to have the buyer introduced to the community by the retiring physician as a professional associate for a period of time. Several secretaries felt that this is a more valuable arrangement in rural areas than in urban areas.

NO RULES OF THUMB

The buying physician may agree that the location, introduction to old patients or other circumstances will assure a steadier patient load than if he were to start a practice without these advantages. Basically, any inherent money value in these intangibles is reflected in the number of old patients who will continue to come to the buying physician. The buying physician may agree to pay the seller a given percentage of net income received from old patients during the first year or two; new patients during the first year may or may not be considered a separate or additional goodwill item. It should be clear to both parties that generalizations or "rules of thumb" regarding the probable percentage of old patients who will accept the new physician are open to serious question when applied to a given situation. Since prediction is so hazardous, both parties would be well advised to provide for final determinations of this item of goodwill a year or two later, although the formula may be set forth in the contract. This arrangement is considered also in cases in which a partnership or group is dissolved, but often it will involve much more complex formulas for establishing the interest of each member.

Careful consideration from the point of view of medical ethics should be given to any mutually satisfactory arrangement providing payments for the goodwill item out of future income or basing the value of this item on future income.

SPECIALTY PRACTICE

The question of sale or purchase of a specialty practice involves further difficulties. As a specialist depends greatly on referred patients, greater care must be taken to verify the continuation of a sound relationship with referring physicians. A general suggestion, both for a specialty practice and for a general practice, is to consider employment of a young man on a salary basis, with agreement as to terms of eventual sale or shift to partnership activity. In some instances such an agreement might prove more satisfactory to both parties than an outright sale.

CONCLUSIONS

The physician should exercise extreme care in arranging to sell or purchase a practice. Perhaps the best statement on the problem is the following by one of the state secretaries:

The location, the type of practice, the size of the practice and the competition that is present are all factors which must be considered in each individual sale, and it appears that probably there is no formula that can be set up—even with an area such as a state—that would assist in any individual transaction. I am inclined to look on this as an individual business venture that would depend entirely on an agreement between the parties concerned. Even though in the eyes of every one else the purchase price was too high or too low, if it was agreeable to the two parties concerned, it would still be a happy transaction. And for those reasons, it has been the opinion of the society that it would not interfere or attempt to offer any assistance to persons contemplating the purchase of a practice.

Because of the extremely involved professional and financial interests arising out of such negotiations, the Bureau of Medical Economic Research strongly urges that principals make no final

arrangements without the assistance of their attorneys. This is especially true if the transaction cannot be consummated at once but involves payments or professional relationships, such as partnerships, which extend over a period of time. Additional technical information and assistance on legal aspects of these contract matters is available to physicians' attorneys through the Association's Bureau of Legal Medicine and Legislation.

One alternative to the purchase of a practice was suggested by several secretaries—the establishment of a new practice in a community. If, after exploring the advantages and disadvantages of buying a given practice, it appears that there is no singular value in the location, type of practice or tangible goods, the physician can give serious consideration to the selection of another location in the community. It is this alternative which largely accounts for the infrequency of sales and the tenuous value of the goodwill item in medical practices in the United States.

Medical Legislation

STATE LEGISLATION

Massachusetts

Bills Introduced.—H. 89, to amend the medical practice act, proposes to authorize the board to accept the certificate of the national board of medical examiners or the certificate of the national board of examiners for osteopathic physicians and surgeons of the American Osteopathic Association, in place of its own professional examination, provided the applicant has not previously attempted unsuccessfully to secure registration in the state. H. 94, relating to the fees of physicians, proposes that a physician's fee for making an authorized mental and physical examination shall be \$7 plus 20 cents for each mile traveled one way. H. 103, relating to the physical examination of school children, proposes that the board of health shall cause every child in the public schools to be separately and carefully examined at certain intervals to ascertain defects in sight or hearing and other physical defects tending to prevent his receiving the full benefit of his school work. The proposal also requires that a physical record of each child be kept in such form as the department of health may require. H. 934 proposes a resolution to the Congress of the United States memorializing the Congress to enact legislation providing for the establishment of a National Science Foundation with the appropriation of sufficient funds to encourage scientific research to be conducted which shall be made available to the directors of the armed forces and insure national security in the future. H. 978, to amend the medical practice act, proposes to authorize any person whose certificate has been suspended, revoked or canceled to file a bill in equity within ninety days for the purpose of reviewing such suspension, revocation or cancellation. H. 991, to amend the workmen's compensation act, proposes that the employee's physician's fee shall not be less than the highest fee which the insurer agreed to pay any physician who appears and testifies in its behalf. H. 999 and S. 231 propose the enactment of a Massachusetts cash sickness compensation act. H. 1069 to amend the law relating to the sale and distribution of drugs and medicines, proposes that no harmful drug shall be sold at retail or dispensed or given away to any person except on the written prescription of a physician, dentist or veterinarian and that no prescription for a hypnotic or somnifacient drug or any other harmful drug shall be renewed or refilled by a pharmacist if the prescription bears any indication that it is not to be renewed or refilled. "Harmful drug" is then defined by the proposal as including amldopyrine, "benzedrine," cantharides, cinchophen, digitalis, dinitroresol, dinitrophenol, ergot, estrogen, natural or synthetic, barbituric acid, chloral hydrate, paraldehyde, sulfonamide drugs, thyroid, oil of croton, oil of pennyroyal, oil of savin and oil of tansy, and any other drug deemed by the department of public health or the board of registration in pharmacy to be a harmful drug. H. 1071 proposes that no licensed physician in the state shall be discriminated against or refused the right to practice his medical profession in any public hospital supported by public funds because said physician is not a member of a private medical society. H. 1074 and S. 348 propose to require certain food handlers to undergo regular physical examinations for tuberculosis or any other communicable disease which might endanger any person with whom he or she may come in contact. H. 1082 and H. 1038 propose to require any person who purchases or acquires a dog, cat or bird to be used for experimentation or mutilation while alive to keep a record and submit a report to the commission of public safety of each such transaction showing the source from which such animal or bird was obtained. H. 1090 proposes to prohibit the vivisection of any living dog within the commonwealth of Massachusetts. H. 1097 and S. 264 propose to prohibit any person from experimenting on living animals without a license from the state board of registration in veterinary medicine. Surgical experiments on such animals are permitted in certain specified circumstances. H. 1280, to amend the workmen's compensation law, proposes that the reasonable cost of a physician's service shall include a routine laboratory service fee for such service which should be allowed to every patient in order to diagnose honestly his injury, his condition and the effect of such condition on the injury. The reasonable cost of a physician's services would also include laboratory fees, x-ray fees and court witness fees.

for the time which the physician spent in court. H. 1463 proposes the creation of a Massachusetts cash sickness compensation fund. H. 1526 proposes to repeal all existing laws requiring vaccination. S. 230 proposes the enactment of a nonoccupational accident and sickness benefits law. S. 752 proposes the creation of a board of registration of chiropractors and defines chiropractic as "the science of locating and removing, by hand adjustment only, interference with the transmission or expression of nerve force in the human body, by the correction of misalignment of subluxations of the vertebral column. It excludes operative surgery, prescription or use of drugs or medicine or the practice of obstetrics, except that the x-ray may be used solely for the purposes of examinations; chiropractor is defined as a person who lawfully practices chiropractic."

Mississippi

Bills Introduced.—H. 24 proposes an appropriation to the state building commission for the purpose of erecting and equipping necessary buildings for a fully accredited Grade A four-year medical college, as a department of the University of Mississippi. H. 13 proposes the enactment of a Mississippi Workmen's Compensation Act.

New York

Bills Introduced.—A. 143 and S. 139 propose to repeal the existing law requiring persons, firms or corporations engaged in the business of procuring persons as blood donors to be licensed by the local health officer and requiring blood donors to present a certificate from a physician showing satisfactory physical condition before making the blood donation. A. 187, A. 275, S. 287, S. 301 and S. 371, to amend the unemployment compensation law, propose to authorize the payment of benefits to persons unemployed because of illness or disability, where such illness or disability is certified by a physician or surgeon duly licensed to practice in the state of New York. A. 362 proposes to regulate the working hours of registered professional nurses. A. 109, S. 285 and S. 410, to amend the unemployment insurance law, propose to extend the benefits thereof to persons employed by charitable and nonprofit institutions.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Donald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 6-7. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Philadelphia, Feb. 26. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Central Surgical Association, Chicago, Drake Hotel, Feb. 19-21. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 10-13. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

National Conference on Medical Service, Chicago, Palmer House, Feb. 8. Dr. Edward F. Sladek, 232 E. Front St., Traverse City, Mich., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, Feb. 23-26. Dr. Max M. Green, 1430 Tulane Ave., Room 105, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Los Angeles, Ambassador Hotel, Feb. 24-28. Dr. Carleton Mathewson Jr., Stanford Univ. Hospital, San Francisco, Secretary.

Tri-States Medical Association of the Carolinas and Virginia, Charleston, S. C., Fort Sumter Hotel, Feb. 9-10. Dr. James M. Northington, 306 N. Tryon St., Charlotte 2, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

Washington Letter

(From a Special Correspondent)

Jan. 29, 1947.

Taft Says Administration Health Bill Would Nationalize Medicine

In answer to a query following his address to the American Public Relations Association, Senator Robert A. Taft of Ohio, chairman of the Senate Republican steering committee, charged that the Wagner-Murray-Dingell bill would "not only socialize medicine but would nationalize medicine." He declared that the measure would actually provide some \$5,000,000,000 in revenue to Washington bureaus to distribute for free medical aid. The Taft-Smith-Ball-Donnell bill, on the other hand, would give free medical care only to those who cannot afford it. Speaking in general of his proposed health, welfare, housing and educational program, Senator Taft said: "I have a strong feeling that in this country if we have a large enough production we can try to abolish hardship and poverty. Whether through their own misfortune or not, there always seems to be a group that is bound to be behind. I think that the other 80 per cent of the people can try to bring them up to a reasonable standard of living in health, housing and education."

Reports Veterans' Medicine Suffers from Lack of Funds

Dr. Paul B. Magnuson, medical director of the Veterans Administration, declared that medical activities of the agency are being held down "all along the line" to stay within budgetary limits. Recently the Disabled American Veterans informed members of Congress of the financial plight of the veterans' medical program when they recommended a \$32,000,000 deficiency appropriation. Dr. Magnuson said that he does not expect to ask Congress for such an appropriation at this time, but he has urged that steps be taken so that there will be no repetition of the current situation. He reported that the hospital program will meet difficult times in four months when about 1,400 young military physicians assigned to the agency—those trained through the AST and the Navy V-12 programs, become eligible for release from the service. Great difficulty is now being experienced in the outpatient service, where officials claim that the number of applications for treatment are far in excess of such requests a year ago. Dr. Magnuson reported that approximately 500,000 veterans are awaiting dental treatment and about 70,000 others are awaiting examinations for outpatient medical care. Dr. Magnuson informed a press conference that he is preparing for the American Medical Association a list of the names of physicians suspected of "chiseling" on "fee basis" treatment for veterans, under the program whereby the government reimburses physicians for treatment given. Dr. E. M. Kennedy of the Veterans Administration dental service said that dental costs are taking some 70 per cent of the amount set aside for outpatient care. The medical budget for the current year totals \$452,000,000, of which \$210,000,000 is for salaries of all personnel. Salaries of Veterans Administration doctors and dentists total \$40,000,000. Of the remaining \$242,000,000, the sum of \$77,000,000 is for outpatient medical and dental programs.

Delay in Ratifying World Health Organization Note

The *Washington Post* commented editorially on the delay in ratifying the World Health Organization's constitution by all twenty-six members of the United Nations. To date seventeen nations have ratified, but Soviet Russia and the United States are among those that have not done so. When final ratification is obtained, the first World Health Assembly will be held within six months and the World Health Organization will become a full fledged member of the U. N. family. The *Post* commented: "Congress has, indeed, approved in principle, with some minor reservations, but the ratification bill was lost in the rush of the closing days of the last regular session of Congress. However, W. H. O. has not been inactive. Its work is being carried on by an Interim Commission, on which the United States is represented, the commission having its headquarters in New York and its technical office in Geneva, Switzerland. . . . Health problems are universal and are readily understood by even the simplest minds. Here is one international activity on which mankind should be able to unite."

GOVERNMENT SERVICES

NAVY

ONE YEAR EXPEDITION TO AFRICA

The Naval Medical Unit of the University of California's African Expedition sailed for Egypt January 14 to begin a year's research aimed to implement the prevention and cure of tropical diseases. Heading the naval unit is Comdr. J. M. Amberson (MC), U.S.N.; others in the unit are Comdr. T. K. Ruebush (MSC), parasitologist; E. Schwarz, zoologist; Chief Pharmacist Mate D. K. Lawless, parasitology technician, and Photographers Mate (second class) Harley S. Cope Jr., all of the Naval Medical School, as well as Mr. Harry Hoogstrall, entomologist, of the Field Museum, Chicago. The expedition will leave Alexandria, Egypt, early in February and will follow a southerly course through Central Africa to the Cape of Good Hope. The itinerary of the trip has been based on months of research and planning. Emphasis will be placed on making surveys and collections in certain areas. The safari will go through the Nubian Desert and will explore an area in which major collections were last made in 1830 by Ruppell, Hemprich and Ehrenberg. Collections will also be made in the Nuba Mountains and in the Jezira triangle, between the White and Blue Nile rivers.

From April to July Nairobi will be headquarters for a survey of Nerya, Uganda, the eastern Belgian Congo and, tentatively, Abyssinian Somaliland. During the wet months work will be done in the northern and northeastern areas, to include Lake Rudolf, the coastal country toward Somaliland, Pemba and Zanzibar Islands, and Central Tanganyika. Uganda, the Belgian Congo and the high mountains will have to be surveyed late in May and June.

While in the Union of South Africa the medical group will gather evidence relating to the effect of industrialization on the health condition of the African Negro. The shift of population from the tropics to the settled southern area will be considered.

The naval group will attempt to make a representative collection of South African flora and fauna for American institutions. The medical unit will seek material to be used for teaching purposes at the Naval Medical School, Bethesda, Md. Anatomic and pathologic specimens, blood smears, protozoa and bacteria, vectors of parasites, intermediate hosts and vertebrates, as well as live specimens to be used as laboratory animals, and pertinent photographic records will comprise part of the documentary evidence to be procured. New drugs and chemicals will be tested for control of infections, parasites and pests, and cooperation with local health authorities and research institutions will be sought.

MEETING OF RESERVE CONSULTANTS

The Reserve Consultants Board to the Bureau of Medicine and Surgery, Navy Department, held its annual meeting at the National Naval Medical Center, Bethesda, Md., on January 9. Dr. Winchell M. Craig, Rochester, Minn., is chairman of the board, which consists of former members of the Medical Department of the Navy. The agenda was comprised chiefly of items relating to the graduate training program of the Naval Medical Department. The amount of training to be given, the eligibility requirements for graduate training and the location of such training facilities were topics under discussion. The group was addressed by Rear Admiral Clifford A. Swanson, Surgeon General of the Navy.

MISCELLANEOUS

NEW COMMITTEE ON ISOTOPE DISTRIBUTION

The Atomic Energy Commission has appointed a new Advisory Committee on Isotope Distribution. This group will recommend to the commission new policies governing the distribution of isotopes, will review existing policies and will act as adviser to the Isotopes Division of the Atomic Energy Commission on allocation of isotopic materials. G. Failla, Columbia University Medical School, New York, is chairman of the new committee; other members are Hymer L. Friedell, Western Reserve University, Cleveland; A. H. Holland Jr., medical adviser, Oak Ridge, Tenn.; J. G. Hamilton, University of California; Joseph W. Kennedy, Washington University, St. Louis; Robley D. Evans, Massachusetts Institute of Technology; Robert F. Mehl, Carnegie Institute of Technology; Austin M. Brues, Argonne National Laboratory, Chicago; L. N. Nims, Brookhaven National Laboratory, Upton, Long Island, N. Y.; H. A. Barker, University of California, Berkeley; Henry Borsook, California Institute of Technology, Pasadena, and Paul C. Aebersold, Oak Ridge, Tenn.

A Subcommittee on Human Applications will consist of Drs. Failla, Friedell, Hamilton and Holland. Membership of a Subcommittee on Allocation will be Drs. Kennedy, Nims, Mehl, Brues, Evans, Barker and Borsook. Dr. Aebersold will serve as secretary to the committee and its subcommittees and as liaison representative of the Atomic Energy Commission.

The new committee held its first meeting in Washington, D. C., January 20. The Atomic Energy Commission has accepted with regret the resignation, effective Dec. 31, 1947, of the Interim Advisory Committee on Isotope Distribution Policy and of its two subcommittees, on human applications and on allocation. The interim committee and its subcommittees were appointed by Major Gen. L. R. Groves of the Manhattan Project. They recommended the general policies on which the Manhattan District initiated its radioisotope distribution program and

under which the commission has continued this activity. The subcommittees assisted the Isotopes Division at Oak Ridge in the review and evaluation of requests for radioactive isotopes and made recommendations on allocations of such materials.

LABORATORY RECEIVES DISTINGUISHED SERVICE AWARD

The laboratory of the Bureau of Entomology and Plant Quarantine at Orlando, Fla., has been awarded the Distinguished Service Award by the U. S. Department of Agriculture "for the development and application of means of protecting military personnel against attack by insects and diseases spread by insects." At the ceremony at the laboratory, January 24, the award was presented by the assistant secretary of agriculture, Mr. Charles F. Brannon. The research which the laboratory conducted during the war on these problems was sponsored by the Army and the Navy and made possible by the transfer of funds to the Department of Agriculture by the Office of Scientific Research and Development. During the afternoon of January 24 the laboratory held open house to enable visitors to see the laboratory and discuss the activities now under way on various arthropods that attack man.

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration announces a sale of miscellaneous drugs and medical supplies from January 27 to February 16. Sales will be made through War Assets Administration customer service centers which are located in numerous large cities throughout the country. Veterans have certain priorities with respect to the sale. Orders sent to any customer service center must be received on or before February 16.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

University Appointments.—Dr. Frank Princi, Denver, has been appointed director of the Division of industrial medicine and assistant professor of medicine at the University of Colorado Medical Center. Dr. Princi is a graduate of the University of Colorado School of Medicine.

Dr. Stuart G. Smith, Washington, D. C., has joined the medical center staff to teach in the department of anatomy. Dr. Smith is a graduate of Western Reserve Medical School, Cleveland.

Open Ward for Tuberculous Patients.—A new ward for the care of patients with tuberculosis will be opened at Colorado General Hospital, Denver, about February 1 through alterations of a ward used for the care of patients with poliomyelitis for the past year and a half. About twenty-eight patients can be accommodated, priority being given to those requiring surgical operation. Provision for the ward was made by the legislature as the first step to be taken by the state for hospital care of tuberculous patients. Selection of the staff is being made. The director of nursing at Colorado General Hospital is particularly desirous of hearing from nurses and attendants interested in working in this field.

CONNECTICUT

Cancer Conference.—Connecticut's first cancer conference for physicians will be held at the Hotel Taft, New Haven, Thursday, March 25. The conference is being arranged by the Connecticut Cancer Society with the cooperation of the state medical society. The program will present well known national speakers who will discuss cancer with special emphasis on early detection by family physicians and the means available for early treatment.

Appointed to Examining Board.—Dr. Louis P. Hastings, West Hartford, was recently appointed to the Connecticut Medical Examining Board to succeed Dr. Charles J. Bartlett, New Haven, resigned. Dr. Hastings is president of the Hartford County Medical Association and has been on the full time staff of St. Francis Hospital, Hartford, since 1929. Dr. Bartlett was president of the board at the time of his resignation, and his membership was continuous for more than twenty years. He was appointed professor of pathology at Yale University School of Medicine in 1897 and was named professor emeritus in 1917. He has been pathologist at the Grace-New Haven Community Hospital since 1918.

ILLINOIS

Report on Communicable Diseases.—The Illinois state health department reports that about 12 in each thousand of the state's population suffered an attack of one or another of the notifiable diseases during 1947. In the previous year the rate was 16 per thousand. Venereal diseases were responsible for almost half of all cases reported, although figures are below those for venereal disease reported for 1946. Smallpox and scarlet fever fell to the lowest reported incidence on record in the state; diphtheria case reports totaled 174 as compared with 469 for 1946; tuberculosis increased to 7,915 cases as against 7,431 in 1946, an increase attributed to "effective case-finding efforts"; and typhoid accounted for 137 cases as against 106 for 1946.

Chicago

Research on Amino Acid Therapy.—The Hektoen Institute for Medical Research at Cook County Hospital has received its annual grant of \$25,000 from the Biochemical Division of the Interchemical Corporation. This grant is to support research on intravenous amino acid therapy and on the role of individual amino acids in human metabolism. One objective of the research program to be pursued is the formulation of an amino acid mixture to be given by vein that will best satisfy physiologic requirements for nitrogen balance.

Fellowship in Allergy.—The Division of Allergy, Northwestern University Medical School, announces a fellowship for training in allergy. Candidates should have experience in research or in basic sciences. The fellow will receive training

in clinical allergy and in research and may register for an M.S. degree. The stipend is \$1,800 to \$3,000. Similar training, without stipend, is also offered to a candidate whose qualifications do not meet fellowship requirements. For information address Dr. Samuel M. Feinberg, Northwestern University Medical School, Chicago.

Society News.—The North Side Branch Chicago Medical Society will be addressed by the following speakers February 5 in the Drake Hotel at 8 p.m.:

Dr. George F. Lull, Secretary and General Manager of the American Medical Association, Chicago, The American Medical Association and Its Relation to the Public.

Dr. Benjamin M. Baker Jr., Johns Hopkins University, Baltimore, Clinical Aspects of Some Diseases of Collagen Degeneration.

Dr. William F. Rieholf Jr., Johns Hopkins University, Baltimore, Surgical Treatment of Hyperparathyroidism.

The scientific program will be preceded with a fellowship gathering at 5:30 and dinner at 6:30 p.m. Reservations are required.

This Week in Chicago Medicine.—The Chicago Medical Society has inaugurated a weekly mimeographed publication entitled *This Week in Chicago Medicine*, designed to keep the profession posted and to aid out of town physicians who wish to visit clinics, conferences, round tables or other meetings. The society is sending copies to all medical libraries, medical schools and city medical societies in the country; to all Illinois hospitals and hospitals of larger cities in states adjacent to Illinois. Loop hotels have requested copies to give to guests who are physicians. Any doctor planning a trip to Chicago may secure copies of this bulletin by writing to the Chicago Medical Society, 30 North Michigan Avenue, Chicago.

KENTUCKY

Society of Anesthesiology.—The newly organized Kentucky Society of Anesthesiology met in Louisville December 3 and elected Dr. Samuel S. Clark, Louisville, president; Dr. Joseph S. Parker, secretary, and Dr. German P. Dillon Jr., treasurer. The society, which has twenty-eight charter members, will meet once a month in the interest of progress and research in anesthesiology.

MICHIGAN

Postgraduate Courses at Wayne.—Wayne University College of Medicine, Detroit, is offering a full time course in basic ophthalmology from January 15 to June 15. Enrolment in the course is limited to twenty. The fee is \$300. The college is also offering a postgraduate course in the basic sciences from March 15 to June 12.

Appointments to State Board.—Three new appointments to the State Board of Registration in Medicine, subject to senate approval, are Drs. Cyrus B. Gardner Lansing; Leland E. Holly, Muskegon, and Cecil Corley, Jackson. Reappointed for the four year term are Dr. David C. Eisele, Ironwood, and Franklin V. Troost, Holt.

MINNESOTA

Personal.—Dr. Fred W. Wittich, Minneapolis, has been notified by the state department that he has been awarded a diploma for allergy lectures delivered at the Instituto Brasileiro de Historia in Rio de Janeiro, Brazil, in December 1946.

Gift of Annual Lectureship.—The Minnesota Graduate Club and Alpha Xi Undergraduate Chapter of the Phi Delta Epsilon fraternity will present an annual lectureship to the University of Minnesota Medical School, Minneapolis, at a banquet February 26. The first lecture will be given after the banquet in the Medical Sciences Amphitheater of the university by Dr. William Roemmich, Oak Terrace, U. S. Public Health Service, on "The 1947 Chest X-Ray Survey of Hennepin County."

NEBRASKA

Society Election.—The Omaha Mid-West Clinical Society has elected the following Omaha physicians as officers for 1948: Roy W. Fouts, president; Warren Thompson, president-elect; John M. Thomas, secretary and director of clinics, and Louis E. Moon, treasurer. October 25 to 29 are the dates for the 1948 meeting.

University Appointments.—Recent appointments to the faculty of Creighton University School of Medicine, Omaha, include Dr. A. S. Black Jr., assistant in surgery (plastic surgery); Dr. C. F. Lowry, assistant in medicine; D. M. C. Reilly, Ph.D., instructor in biochemistry, and J. M. Severens, Ph.D., assistant professor of bacteriology.

Dr. Bennett Leaves for California.—Dr. Abram E. Bennett, for many years chairman of the department of neuropsychiatry at the University of Nebraska College of Medicine, Omaha, will become affiliated with the Herrick Memorial Hospital, Berkeley, Calif., on March 1. The hospital is opening a new forty bed psychiatric department.

NEW YORK

Ordinance on Atmospheric Pollution.—Niagara Falls is the first city in the United States to adopt an ordinance providing complete coverage for all types of atmospheric pollution—dusts, gases, fumes, mists, vapors, smoke and odors. The ordinance is also unique in setting up an air pollution control board to keep rules flexible. The U. S. Public Health Service, Industrial Hygiene Division, assisted in this project at the request of the city and state.

Professional Recruitment and Training.—Dr. Franklyn B. Amos, Delmar, has been appointed director of the state health department's new office of professional recruitment and training, effective January 1. He will supervise programs to train physicians, nurses, engineers, dentists and health educators for public health work. Dr. Amos, a graduate of Syracuse University College of Medicine, 1931, has been with the state health department since 1935 and has been director of local health administration since 1940.

Centennial of Community Service.—The Community Service Society is celebrating its centennial year with a series of scientific conferences, bringing together leaders in the fields of medicine, psychiatry, the social sciences, public health and education beginning January 22 and continuing through April. The theme is "The Family in Tomorrow's World." Dr. Thomas M. French, Chicago, spoke on "Personal Interaction and Growth in Family Life" at the first of three symposiums at the Hotel Roosevelt on January 29. On January 30 Dr. Marianne Kris, New York, spoke on "Implications (of Child Rearing) for Family and Community"; Dr. Nathan W. Ackerman, New York, on "Adaptive Problems of the Adolescent Personality," and Dr. Viola Bernard, New York, "Implications (of Adolescence) for Family and Community."

The Community Service Society is said to be the largest private nonsectarian family and health agency in the United States. It is the modern outgrowth of two pioneer organizations, the Association for Improving the Condition of the Poor, incorporated in 1848, and the Charity Organization Society, founded in 1882.

New York City

Strausberg Memorial Lecture.—The first Samuel Strausberg Memorial Lecture of the Beth-El Hospital, Brooklyn, will be delivered by Dr. William Goldring, associate professor of medicine at the New York University College of Medicine, February 18 in the Kings County Medical Society building. Dr. Goldring's topic will be "Present Status of Medical and Surgical Treatment of Hypertension." The lecture is in memory of the late Mr. Strausberg, president of the hospital, 1941 to 1946.

Research on Problems of Aging.—Columbia University, New York, has been awarded a grant of \$31,500 by the Rockefeller Foundation for "investigation of the interaction of hereditary and environmental factors in relation to: problems of aging." The grant, a renewal of an original gift made by the foundation in 1945 to the New York State Psychiatric Institute, a part of the Columbia-Presbyterian Medical Center, will carry on a three year or longer investigation on the health status and activities of twins over 60 years of age. A number of state and private agencies are cooperating. There is still a need for twins of more than 60 years of age in New York City to participate in the study. Those interested are asked to communicate with the Department of Psychiatry, 722 West 168th Street, New York 32.

NORTH CAROLINA

Narcotic Violation.—The Bureau of Narcotics, Washington, D. C., reports that Dr. Wiley R. Young, Angier, N. C., pleaded guilty to violation of the federal narcotic law in the U. S. District Court at Greensboro on Dec. 2, 1947. His sentence of three years was suspended; he was placed on probation for a period of five years and was fined \$500.

UTAH

Utah Medical Foundation Lecture.—Dr. Edith L. Potter, Chicago, will deliver the second series of the annual Obstetric and Gynecological Lectureship on "Immunization to the Rh Factor" and "Etiology of Maldevelopment of the Human Fetus" at the University of Utah, Salt Lake City, February 16 and 17.

WEST VIRGINIA

First Woman to Head Component Society.—Dr. S. Elizabeth McFetridge, Shepherdstown, has been elected president of the Eastern Panhandle Medical Society, the first woman to be named president of a component society of the West Virginia State Medical Association. In addition to her specialty of anesthesiology, Dr. McFetridge is engaged in general practice. She was recently named chairman of the association's Committee on Maternal Welfare.

Hunter Memorial Library.—Plans have been approved for establishing the Hunter Library at the Herbert J. Thomas Memorial Hospital, South Charleston, in memory of Dr. J. Ross Hunter, Charleston, who was president of the staff at the time of his death on Dec. 31, 1947. Contributions are being accepted by Mr. T. W. Patterson, hospital administrator. The long-range plan will probably include a circulating library for patients as well as the medical library proposed for the use of the staff.

Licensure to Practice.—Under a new regulation of the public health council a qualified applicant for licensure to practice medicine in West Virginia will hereafter be permitted to practice in a specified area during the interim between the filing of his application and the date of the next regular meeting of the public health council, at which time he will be required to appear for examination. Graduates of unclassified foreign medical schools will be permitted to serve as interns or residents in private hospitals and state institutions, provided their services are requested by the proper officials prior to employment and provided that they present their credentials to the public health council in regular session and receive permission so to serve. However, they will not be permitted to serve outside the hospitals or institutions. This regulation does not in any way rescind a previous regulation of the council, which bars graduates of Class B schools from practice in hospitals in this state after July 1, 1948.

GENERAL

Director of Information.—Joseph Hirsh, New York, associate director, Research Council on Problems of Alcohol, has been granted a leave of absence to assume the position of director of public information, World Health Organization, Interim Commission, of the United Nations. He participated in the fifth session of the World Health Organization, Interim Commission, in Geneva, Switzerland, January 1948.

Appoint Director of Public Health Nursing.—Miss Anna Fillmore, R.N., New York, has been appointed general director of the National Organization for Public Health Nursing to succeed Miss Ruth Houlton, R.N. Miss Fillmore has been with the Visiting Nurse Service of New York since 1940. Previously she was director of the Bureau of Public Health Nursing in the Utah State Health Department and assistant director of the American Nurses Association of New York.

Dr. Talbott to Edit Medicine.—Dr. John H. Talbott, professor of medicine, University of Buffalo Medical School, and head of the department of medicine, Buffalo General Hospital, has succeeded Dr. Alan M. Chesney, Baltimore, as managing editor of *Medicine*. Dr. Talbott received the M.D. degree from Harvard Medical School in 1929, and from 1931 to 1946 was associated with that school and the Massachusetts General Hospital in various capacities, being associate in medicine from 1935 to 1946.

National Foundation's Decade of Progress.—Basil O'Connor, head of the National Foundation for Infantile Paralysis, has reported that the organization in its first decade has spent \$35,000,000 in medical care for victims of poliomyelitis and \$13,000,000 for research on the disease. It has helped 88,000 patients financially, obtained admission for patients in four hundred and seventeen hospitals, started five hundred and forty research and education projects and trained thirteen hundred professional workers in the treatment of patients with poliomyelitis.

American Physicians Exhibit Art in Argentina.—On invitation from the Argentine government (*THE JOURNAL*, Sept. 20, 1947, p. 172) twenty-two physicians of the American Physicians Art Association submitted pieces in an exhibit of fine arts in Buenos Aires Nov. 24, 1947. Gold medals were awarded to Dr. Max Thorek, Chicago, and Dr. Homer Wheelen, Seattle, Wash. The art pieces were shipped prepaid by air freight through the courtesy of Mead Johnson & Company. Members of the American Physicians Art Association and the American Physicians Literary Guild have been invited to exhibit again at the next art show. A return invitation has been extended for the artists and literary physicians of Buenos Aires to exhibit in Chicago next June.

Lynch Memorial Essay Contest.—The Pacific Coast Obstetrical and Gynecological Society will hold its second Frank W. Lynch Memorial Essay Contest during the coming year. It is open to physicians who have been in practice for less than ten years or who have not been certified by the American Board of Obstetrics and Gynecology, Inc. Any topic may be selected in the obstetric or gynecologic field and may cover either clinical investigations or laboratory research. The prize for the best essay submitted is \$100, and the winner will present his paper at the fall meeting of the society. Essays should be in the hands of the secretary, Dr. R. Glenn Craig, 490 Post Street, San Francisco 2, by August 1. Dr. Frank Lynch was first president of the society.

Conference for Children with Orthopedic Defects.—The National Foundation for Infantile Paralysis is sponsoring a conference for the improvement of educational opportunities for children with orthopedic defects who receive their schooling in hospitals and convalescent centers. The conference is being held at the Hotel Ambassador, Atlantic City, N. J., February 26 and 27 in conjunction with the annual convention of the American Association of School Administrators. Teachers in the two hundred and fifty-seven treatment centers of the country that have academic facilities, physicians, school administrators, hospital administrators, staffs of teacher-training centers, nurses, physical and occupational therapists, medical social workers and education program leaders of civic and women's clubs are being invited to attend. Reservations should be made directly with the Hotel Ambassador.

Dr. Ruggles Heads Mental Hygiene Committee.—Dr. Arthur H. Ruggles, Providence, R. I., has been elected president of the National Committee for Mental Hygiene to succeed Eugene Meyer, publisher of the *Washington Post*. Dr. Ruggles resigned January 1 from the superintendency of Butler Hospital, a position that he held for twenty-six years. The board of trustees retained Dr. Ruggles as general consultant. A graduate of Harvard Medical School, Boston, 1906, Dr. Ruggles was appointed assistant superintendent at the hospital in 1909 and superintendent in 1922. He is a consultant in mental hygiene in the department of university health, lecturer in psychiatry at Yale University, New Haven, Conn., and a consultant, U. S. Public Health Service. He is a former president of the American Psychiatric Association, the New England Society for Psychiatry and the Rhode Island Medical Society.

British Journals Available in the United States.—The British Medical Society has appointed Grune & Stratton, Inc., medical publishers, 381 Fourth Avenue, New York 16, as sole agents for the United States of all its periodical publications, beginning January 1948. The journals are the *British Medical Journal*, published weekly, at \$14 a year; *Abstracts of World Medicine*, published monthly, \$13 a year; the *Abstracts of World Surgery, Obstetrics and Gynecology*, published monthly, \$9 a year, and the following quarterlies at \$5.50 a year: *Annals of the Rheumatic Diseases*; *Archives of Disease in Childhood*; *British Heart Journal*; *British Journal of Industrial Medicine*; *British Journal of Pharmacology and Chemotherapy*; *British Journal of Social Medicine*; *British Journal of Venereal Diseases*; *Journal of Clinical Pathology*; *Journal of Neurology, Neurosurgery and Psychiatry*, and *Thorax*.

Dr. Ida Bengtson Receives Typhus Commission Award.—Ida A. Bengtson, Ph.D., formerly of Bethesda, Md., has been awarded the United States of America Typhus Commission Medal for exceptionally meritorious service during 1943 to 1945 in the investigation and control of rickettsial infections. The award to Dr. Bengtson was made shortly before the recent disbandment of the wartime commission, but presentation was postponed until her return from an extended visit in the West. While associated with the commission, Dr. Bengtson "contributed to the improvement of typhus vaccine, the development of the complement fixation tests and the differentiation of organisms causing various types of typhus fevers." In the ten years before her retirement from the National Institute of Health in January 1946, Dr. Bengtson devoted her investigations to the rickettsial group of diseases and was among the first to study the cultivation of rickettsias in eggs. She was with the U. S. Public Health Service for twenty-six years.

Fellowships Available in Public Health.—Fellowships leading to a master's degree in public health in the field of health education are again being offered to any qualified citizen of the United States between the ages of 22 and 40. Funds are available through a grant from the National Foundation for Infantile Paralysis. Candidates must hold a bachelor's degree and must be able to meet the entrance requirements of the accredited school of public health of their choice. In addition to the bachelor's degree courses in the biologic sciences, sociol-

ogy and education are required. Training in public speaking, journalism and psychology and work in public health or a related field is considered desirable. The fellowship consists of eight or nine months' academic work, which begins with the fall term in 1948, and three months of supervised field experience in community health education activities in a local health department. Veterans are encouraged to apply and will be paid the difference between their subsistence allowance under the GI Bill of Rights and the monthly stipend of \$100 for single veterans or \$150 for married veterans. Employees of state or local health departments are not eligible, since federal grants-in-aid are provided through the states for such training. Information may be obtained from the National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

LATIN AMERICA

Two New Medical Journals.—*Jornada Medica*, a monthly Argentine medical journal with headquarters at Calle Cordoba 2218, Buenos Aires, recently appeared. Dr. Horacio Basabe is the editor. *Revista Panamericana de Medicina y Cirugia del Torax*, a Spanish quarterly journal with summaries in English, with headquarters at Calle de Amazonas 96, Mexico, D. F., Mexico, recently appeared with Dr. Donato G. Alarcón of that city as editor.

Pan-American Doctors' Club First Scientific Session.—From February 28 to March 1 the Pan-American Doctors' Club will hold its first scientific sessions at the club home, San Miguel Regla, Hidalgo, Mexico. There will be papers on health problems and opportunities for members and guests to enjoy recreational activities. Housing accommodations are limited, but a few nonmember guests can be cared for if reservations are made in advance. For information address Dr. Clarence A. Mills, Secretary, Cincinnati General Hospital, Cincinnati, Ohio.

FOREIGN

International Society of Pathologists.—An international association of societies devoted to clinical pathology was established at meetings in Paris, France, November 21-22 in the course of the first International Congress of the Société Française de Biologie Clinique. Delegates and observers attended from Belgium, Czechoslovakia, Denmark, France, Great Britain, Greece, Italy, Peru and the United States. A provisional constitution drawn in general conformance with the rules established by UNESCO for its associated international bodies establishes the governing body of the International Federation as a council or commission of the delegates from the national member societies. The council acts through an Executive Committee of six members. The English and French texts of the statutes will come up for ratification at a meeting of the council, which it is hoped to hold next summer. The conference elected officers as follows: Dr. Sidney C. Dyke, Wolverhampton, England, president; Drs. D. Durupt, France, and Josef Ungar, Czechoslovakia and England, secretaries; Professor Raoul Kourilski, France, vice president, and Dr. W. H. McMenemey, England, treasurer. The second office of vice president was left vacant in the hope that it might be filled by a representative of the United States. The conference defined the term "clinical pathology" as consisting in "the application of pathology and all its related sciences to clinical medicine."

National societies devoted to clinical biology as defined are invited to communicate with the secretary-general, Dr. D. Durupt, 20 Rue de la Pompe, Paris, or the assistant secretary, Dr. J. Ungar, Claxo Laboratories, Greenford, Middlesex, England.

Marriages

JOHN BLACKWELL SUTPHIN, Trenton, N. J., to Miss Caroline Gibbs Hunter in Columbia, S. C., Oct. 17, 1947.

GEORGE CARTWRIGHT ADICKES, York, S. C., to Miss Floride Cantey Des Champs in Columbia, Oct. 18, 1947.

EDWARD G. HASKELL JR., Jacksonville, Fla., to Miss Gale Deane Shumate of Bluefield, W. Va., recently.

JAMES KEITH PALMER, Sumter, S. C., to Miss Nancy Louise Buie of Rochester, Minn., Sept. 27, 1947.

ANGELA B. ADAMS to Dr. CHESTER R. JABLONOSKI, both of Cleveland, Nov. 12, 1947.

ALLEN WIDOME to Miss Fay Berger, both of Washington, D. C., Feb. 22, 1947.

ROBERT W. TUFFT to Miss Dorothy Galt, both of San Francisco, recently.

Deaths

Max Pinner, Berkeley, Calif.; born in Berlin, Germany, Nov. 28, 1891; Eberhard-Karls-Universität Medizinische Fakultät, Tübingen, Württemberg, Germany, 1920; became instructor in pathology and bacteriology at the University of Illinois College of Medicine in Chicago, later director of laboratories of the Maybury Sanatorium in Northville, Mich., and pathologist at the Herman Kiefer Hospital in Detroit; director of laboratories and research at the Desert Sanatorium in Tucson, Ariz., from 1930 to 1935; diagnostic pathologist for the state tuberculosis hospitals of New York; from 1938 to 1946 on the staff of the Montefiore Hospital for Chronic Diseases in New York; affiliated with Montefiore County Sanatorium in Bedford Hills, N. Y.; served as clinical professor of medicine at Columbia University College of Physicians and Surgeons in New York; specialist certified by the American Board of Pathology; member of the American Sanatorium Association, Society for Experimental Biology and Medicine, American Association for Thoracic Surgery and the American Association for Pathologists and Bacteriologists; fellow of the American College of Physicians; in 1946 awarded the Trudeau Medal of the National Tuberculosis Association; served in the German Army during World War I; author of "Pulmonary Tuberculosis in the Adult"; editor of the *American Review of Tuberculosis*; died January 7, aged 57.

David Robert Climenko, Fort Bayard, N. Mex.; born in New York Aug. 28, 1906; University of Edinburgh Faculty of Medicine, Scotland, 1931; assistant in physiology at the University of Edinburgh from 1929 to 1932; assistant professor of physiology and pharmacology, University of Alberta, Canada, from 1932 to 1934; lecturer in pharmacology at Cornell University in New York, 1934-1935; pharmacologist for the American Cyanamid Company in Stamford, Conn., from 1935 to 1940; pharmacologist for the Winthrop Chemical Company, Rensselaer, N. Y., from 1940 to 1942; associate in biochemistry from 1940 to 1943, later instructor in medicine and research associate in medicine at the Albany Medical College in Albany, N. Y.; served during World War II; affiliated with the Veterans Administration Hospital; died recently, aged 41.

Sidney Isaac Schwab ♂ St. Louis; born in Memphis, Tenn., Nov. 22, 1871; Harvard Medical School, Boston, 1896; later studied at universities in Paris, Berlin and Vienna; professor emeritus of clinical neurology at the Washington University School of Medicine; member and past president of the American Neurological Association; formerly councilor of the medical council of the U. S. Veterans Bureau in Washington; served overseas during World War I; affiliated with St. Louis Children's and Maternity Hospital, Jewish Hospital and the Barnes Hospital; author of "The Adolescent: His Conflicts and Escapes"; on the editorial staff of the *Journal of Nervous and Mental Disease*; died in Boston Nov. 12, 1947, aged 75, of burns.

Earl Cooper, Augusta, Ill.; born in 1879; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1905; member of the American Medical Association; chairman of the county board of assistance; past president of the Hancock County Medical Society; president of the town board of health; physician for the county Selective Service Board during World War II; formerly affiliated with the Illinois Soldiers' and Sailors' Home in Quincy, where he was on the staff of St. Mary's Hospital; served on the staff of the Graham Protestant Hospital in Keokuk, Iowa; died Nov. 5, 1947, aged 68, of coronary thrombosis.

Earl Edward Van Derwerker ♂ New York; Columbia University College of Physicians and Surgeons, New York, 1917; assistant clinical professor of orthopedic surgery at his alma mater; specialist certified by the American Board of Orthopedic Surgery; member of the American Academy of Orthopedic Surgery; fellow of the American College of Surgeons; an officer during World War I; served on the staff of Blythedale Home in Hawthorne, Lawrence Hospital in Bronxville and the Hospital for Special Surgery; died in Newtown, Conn., Nov. 2, 1947, aged 57, of coronary thrombosis.

Louis Storrow Greene ♂ Washington, D. C.; born in 1872; University of Virginia Department of Medicine, Charlottesville, 1895; specialist certified by the American Board of Ophthalmology; served as associate professor of ophthalmology at the Georgetown University School of Medicine; past president of the American Ophthalmological Society; fellow of the American College of Surgeons; head of the eye examining service for the draft board during World War I; affiliated with the Episcopal Eye, Ear and Throat Hospital; died Nov. 12, 1947, aged 74, of coronary thrombosis and cerebral hemorrhage.

Louis Ferdinand Alrutz ♂ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; past president of the Aux Plaines branch of the Chicago Medical Society; served on the staff of West Suburban Hospital in Oak Park; died Nov. 26, 1947, aged 71, of coronary thrombosis.

John Baxter Bain, Lawrence, Mass.; Harvard Medical School, Boston, 1902; member of the American Medical Association; for many years affiliated with Lawrence General Hospital; died in New England Deaconess Hospital, Boston, recently, aged 68, of uremia and myocardial insufficiency.

Harvey M. Beaver, Kansas City, Mo.; Louisville (Ky.) Medical College, 1888; at one time on the faculty of Harvey Medical College in Chicago and the College of Physicians and Surgeons in Kansas City, Kan.; formerly practiced in Huntington, Ind., where he served as county coroner; died recently, aged 87, of interstitial nephritis.

George Crocket Becket, Lakeville, Conn.; Cornell University Medical College, New York, 1900; served on the staff of the Essex County Memorial Hospital in East Orange, N. J.; died in the Hudson City (N. Y.) Hospital Nov. 11, 1947, aged 79, of pulmonary edema and cerebral hemorrhage.

Joseph Jackson Blitch, Yonkers Island, S. C.; University of the South Medical Department, Sewanee, Tenn., 1901; died in Charleston recently, aged 79.

Charles Arthur Brake, Norman, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1917; member of the American Psychiatric Association; served during World War I; assistant professor of psychiatry at the University of Oklahoma School of Medicine; affiliated with the Central Oklahoma State Hospital; died recently, aged 52, of cerebral hemorrhage.

James Cooper Bright, Fall River, Mass.; Jefferson Medical College of Philadelphia, 1907; member of the American Medical Association; died in the State Hospital, Taunton, Nov. 12, 1947, aged 74, of arteriosclerotic heart disease.

James Blaine Brown, Pell Lake, Wis.; Loyola University School of Medicine, Chicago, 1916; died Nov. 8, 1947, aged 63, of acute coronary occlusion.

William Turner Carstarphen ♂ Westport, Conn.; Jefferson Medical College of Philadelphia, 1904; member of the Medical Society of the State of New York; at one time on the faculty of Wake Forest (N. C.) College; served during World War I; chief medical officer at the Japanese-American camp in Arkansas and Colorado during World War II; died in the Kingston (Ontario) General Hospital Nov. 2, 1947, aged 72, of carcinoma of the rectum.

Simeon Cohen, Meriden, Conn.; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1921; died in the Meriden Hospital Nov. 2, 1947, aged 52 of malignancy of right testicle.

Ross Alvah Cooper, Carmel, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the American Medical Association; served during World War I; member of the staff of the Methodist Hospital in Indianapolis, where he died Nov. 8, 1947, aged 65, of cerebral hemorrhage.

James Harry Cox, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; died in the Veterans Administration Hospital, Dearborn, Nov. 24, 1947, aged 75, of arteriosclerotic heart disease.

Harry Lee D'Arms, Hector, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; served as county coroner; died recently, aged 79, of uremia.

Charles A. Davis, Kennedy, Ala.; Birmingham Medical College, 1912; member of the American Medical Association; died recently, aged 63.

Jules Jehin De Prume, New York; Université de Paris Faculté de Médecine, France, 1893; Laval University Faculty of Medicine, Quebec, Canada, 1894; affiliated with the Misericordia Hospital; died in the French Hospital Nov. 11, 1947, aged 77, of carcinoma of the large intestine.

Robert Cecil Donham, Beverly Hills, Calif.; University of Southern California School of Medicine, Los Angeles, 1933; member of the American Medical Association; served an internship and residency at the Los Angeles County General Hospital in Los Angeles, where he was a member of the surgical staffs of the California Lutheran and the Methodist hospitals; died recently, aged 43.

John Rose Dyson ♂ Hazleton, Pa.; Medico-Chirurgical College of Philadelphia, 1897; served on the staff of the Hazleton State Hospital; died Nov. 18, 1947, aged 73, of coronary thrombosis.

Rebecca Mortimer Evans, Denton, Texas; Northwestern University Woman's Medical School, Chicago, 1902; died Oct. 30, 1947, aged 75, of cerebral hemorrhage.

Victor Finsand @ San Francisco; University of Illinois College of Medicine, Chicago, 1916; served during World War I; died Nov. 2, 1947, aged 58, of cerebral hemorrhage.

Solomon Greenspahn, Chicago; Rush Medical College, Chicago, 1889; member of the American Medical Association; medical director and treasurer of the American Hospital; died Nov. 17, 1947, aged 80, of coronary thrombosis.

Frank West Harrah @ Columbus, Ohio; Cornell University Medical College, New York, 1920; member of the American Urological Association and the Columbus Academy of Medicine; fellow of the American College of Surgeons; affiliated with Grant, White Cross and Mount Carmel hospitals; died Nov. 6, 1947, aged 55, of cerebral hemorrhage.

Joseph A. Heintzelman, Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1902; died in the Lankenau Hospital Nov. 7, 1947, aged 69, of subacute bacterial endocarditis and bronchopneumonia.

Howard Crosby Hoff, New York; Columbia University College of Physicians and Surgeons, New York, 1907; served on the staffs of West Park and St. Elizabeth's hospitals; died Nov. 21, 1947, aged 63, of coronary thrombosis.

Tarlton Ambrose Hood, Garnett, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1897; member of the American Medical Association; served overseas during World War I; served as county health officer, member of the board of education and chamber of commerce; died Nov. 3, 1947, aged 75, of undulant fever.

William W. Hume, Beckley, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1901; member of the American Medical Association; served as vice president of the West Virginia Public Health Association; for many years county health officer; died Nov. 4, 1947, aged 81, of pneumonia.

J. Newton Hunsberger @ Norristown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the House of Delegates of the American Medical Association from 1923 to 1943; served as chairman of the board of trustees of the Montgomery County Medical Society; past president of the Valley Forge Historical Society; affiliated with the Montgomery Hospital; died Nov. 1, 1947, aged 80, of cerebral hemorrhage.

Ernest Hart Judd @ Springfield, Mass.; Tufts College Medical School, Boston, 1912; medical consultant at the Springfield Hospital; died recently, aged 62, of coronary occlusion.

Dillon James Kennington @ Michigan City, Ind.; Indiana University School of Medicine, Indianapolis, 1937; assistant physician at the Indiana State Prison Hospital; on the staff of St. Anthony's Hospital, where he died Nov. 2, 1947, aged 35, of heart disease.

Edmund Carl Konrad, Cleveland; University of Wooster Medical Department, Cleveland, 1908; served during World War I; affiliated with the Lutheran, Evangelical Deaconess, Grace and Charity hospitals; died recently, aged 63, of coronary thrombosis.

Martin Kutscher @ New York; born in Stapleton, N. Y., Aug. 22, 1883; Columbia University College of Physicians and Surgeons New York, 1905; clinical professor of medicine and associate attending physician at the New York Polyclinic Medical School and Hospital; member of the American Heart Association and the Association for the Study of Internal Secretions; served on the staffs of the City, Lebanon and Midtown hospitals; died recently, aged 64, of myocardial infarction.

Alfons Frederick Landeker @ New York; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1911; died recently, aged 61, of myocarditis.

Edwin F. Landy, Cincinnati; Medical College of Ohio, Cincinnati, 1891; formerly on the faculty of his alma mater; veteran of the Spanish-American War; died Nov. 21, 1947, aged 79, of cerebral arteriosclerosis.

William James Larkin, Chicago; Rush Medical College, Chicago, 1922; member of the American Medical Association; affiliated with St. Francis Hospital in Evanston, Ill.; died in Galesburg, Ill., Nov. 24, 1947, aged 65, of coronary sclerosis.

Lyder Laurits Laugeson, San Diego, Calif.; University of Minnesota Medical School, Minneapolis, 1929; member of the American Medical Association; served during World War II; died Nov. 11, 1947, aged 44, of nephrosis and cirrhosis of the liver.

E. Oscar Lindenmuth @ Indianapolis; Medico-Chirurgical College of Philadelphia, 1906; died in Methodist Hospital recently, aged 75, of uremia and prostatic hypertrophy.

Charles Oscar Lindstrom @ Eagle River, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; graduate in pharmacy; formerly vice president and on the staff of Columbus Hospital in Chicago; health officer; died Nov. 3, 1947, aged 72, of heart disease and pneumonia.

James A. Long, Oxford, Ohio; University of Louisville (Ky.) Medical Department, 1892; member of the American Medical Association and the Indiana State Medical Association; for many years secretary of the board of health in Anderson, Ind.; died in Mercy Hospital, Hamilton, Ohio, Nov. 9, 1947, aged 87, of cardiovascular renal disease.

Leo Martin Maguire, Minneapolis; John A. Creighton Medical College, Omaha, 1912; lieutenant colonel, medical corps, Army of the United States, affiliated with the Veterans Administration during World War II; at the time of his death medical officer for Veterans Administration; died Nov. 10, 1947, aged 59, of injuries received when he fell through a trap door at a hunting club near Minneapolis.

Reuben Maurits @ Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the American Society of Anesthetists; past president of the Grand Rapids Society of Anesthesiology, which he helped organize; served on the staffs of Butterworth Hospital and Blodgett Memorial Hospital, where he died Nov. 11, 1947, aged 77, of subarachnoid hemorrhage and arteriolar nephrosclerosis.

William Dennis McClung, Huntington, W. Va.; College of Physicians and Surgeons, Baltimore, 1907; served in the U. S. Public Health Service during World War I; formerly superintendent of the Spencer (W. Va.) State Hospital and the Huntington State Hospital; died Nov. 2, 1947, aged 71, of injuries received in a fall from a moving automobile at Dickson.

Charles Hugo McKenna, Chicago; Northwestern University Medical School, Chicago, 1913; member of the American Medical Association; fellow of the American College of Surgeons; affiliated with Holy Cross Hospital; died recently, aged 60, of bronchogenic carcinoma of the lung.

Neill Henry McLeod Jr., Raleigh, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1930; member of the American Medical Association; served during World War II; died recently, aged 42, of heart disease.

Clarence Sherman Massey, Wadesboro, N. C.; Howard University College of Medicine, Washington, D. C., 1925; died recently, aged 48, of pneumonia.

James Graham Maxwell, Reno, Nev.; Colorado School of Medicine, Boulder, 1897; died in a hospital at Colorado Springs, Colo., recently, aged 78, of pneumonia.

Diedrich Janssen Meents @ Fort Madison, Iowa; State University of Iowa College of Medicine, Iowa City, 1907; took postgraduate work at Harvard, Berlin and Vienna; at one time assistant professor of pathology and bacteriology at the State University of Iowa; died Nov. 6, 1947, aged 69, of coronary occlusion.

Arthur Nourse Meloy, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1905; died in the Providence Hospital Nov. 1, 1947, aged 75, of subdural hematoma.

George Washington Michell @ Peoria, Ill.; Rush Medical College, Chicago, 1902; medical director of the Michell Farm and the Michell Sanatorium; died Nov. 17, 1947, aged 71, of cerebral hemorrhage.

Philip Earl Moody, Detroit; Detroit College of Medicine, 1902; served on the staffs of the Harper, Crittenden and Providence hospitals; died Nov. 11, 1947, aged 68, of coronary thrombosis.

Hugh Montgomery Orr, La Salle, Ill.; College of Physicians and Surgeons, Baltimore, 1895; for many years mayor; a founder of St. Mary's Hospital; died Nov. 16, 1947, aged 80, of heart disease.

Albert L. Nason, Darling, Miss.; Chattanooga (Tenn.) Medical College, 1905; died in the Baptist Memorial Hospital, Memphis, Tenn., recently, aged 77, of cerebral thrombosis.

Clara Mary Ochs, Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1918; member of the American Medical Association; served on the courtesy staff of the Woman and Children's Hospital in Chicago; died Nov. 19, 1947, aged 71, of carcinoma of the cecum.

David Wilmot Overton, Avon Park, Fla.; University and Bellevue Hospital Medical College, New York, 1899; died recently, aged 80.

Jennie Leigh Kellogg Paris, Hammondsport, N. Y.; University of Buffalo School of Medicine, 1893; died recently, aged 79, of embolism following fracture of femur.

Albert Taylor Parrish, Ovid, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; served as health officer; died recently, aged 89, of senility.

John Patterson, Lexington, Ky.; Hospital College of Medicine, Louisville, 1900; died recently, aged 69, of heart disease and Parkinson's disease.

Merton S. Pearce, St. Petersburg, Fla.; University of Maryland School of Medicine, Baltimore, 1900; died in the Suburban Hospital, Bethesda, Md., Nov. 1, 1947, aged 75, of cerebral hemorrhage.

Benjamin Lane Phillips, Paola, Kan.; University of Kansas School of Medicine, Kansas City, 1907; served as county coroner; died recently, aged 66, of congestive heart failure.

William Giles Phipps, Mount Vernon, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1913; served during World War I; affiliated with Mount Vernon Hospital; died Nov. 2, 1947, aged 61, of myocarditis.

William Aloysius Pindar, North Bergen, N. J.; University and Bellevue Hospital Medical College, New York, 1909; for many years police surgeon; served as a member of the state board of medical examiners and city board of health; medical examiner for selective service during World War II; affiliated with St. Mary's Hospital in Hoboken; died Nov. 12, 1947, aged 63, of coronary thrombosis.

Minor Gibson Porter & Baltimore; University of Maryland School of Medicine, Baltimore, 1885; past president of the Baltimore County Medical Society; medical officer of the county draft board during World War I; formerly mayor of Lonaconing; affiliated with the Church Home and Infirmary and Union Memorial Hospital, where he died recently, aged 82, of a fractured right hip as the result of a fall, bronchopneumonia, and diabetes mellitus.

Randolph Reynolds & Wallingford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1914; served during World War I; formerly affiliated with the Meriden State Tuberculosis Sanatorium in Meriden and the Veterans Home Hospital in Rocky Hill; died recently, aged 61, of coronary occlusion.

Donald Ford Robertson, Rahway, N. J.; Washington University School of Medicine, St. Louis, 1929; associate medical director of Merck & Co., Inc.; died in the Harkness Pavilion, Presbyterian Medical Center, New York, Nov. 8, 1947, aged 44, of leukemia.

Charles Edward Rooney & Santa Monica, Calif.; Creighton University School of Medicine, Omaha, 1905; formerly on the faculty of his alma mater; served on the staffs of Santa Monica and St. John's hospitals; at one time practiced in Yuma, Ariz., where he was physician for the Southern Pacific Company and county health officer; died Nov. 1, 1947, aged 66, of hypertensive heart disease.

William Walter Sames, Hartshorne, Okla.; Missouri Medical College, St. Louis, 1896; member of the American Medical Association; formerly affiliated with the Indian Service; died recently, aged 84.

Paul Henry Sandresky & Buffalo; University of Buffalo School of Medicine, 1911; formerly a minister; affiliated with the Lafayette General Hospital and the Millard Fillmore Hospital, where he died Nov. 16, 1947, aged 68, of acute myocardial infarction.

Thomas H. Sandy, Chicago; Harvey Medical College, Chicago, 1901; member of the American Medical Association; physician for the Continental Illinois National Bank and Trust Company for many years; died at his home in Forest Park, Ill., Nov. 24, 1947, aged 72, of coronary occlusion and arteriosclerosis.

Frederick J. Schaufelberger, Los Angeles; Jefferson Medical College of Philadelphia, 1884; died Nov. 20, 1947, aged 97.

Ernest Edward Schriefer, Cannelton, Ind.; University of Louisville (Ky.) Medical Department, 1906; member of the American Medical Association; past president of the Perry County Medical Society; formerly health officer; medical examiner for the county draft board during World War I; affiliated with the Parkview Hospital, Tell City, where he died, Nov. 3, 1947, aged 67, of cerebral hemorrhage.

Erich Wilhelm Schwartz, Washington, D. C.; Rush Medical College, Chicago, 1914; member of the American Medical Association and the Medical and Chirurgical Faculty of Maryland; at one time professor of physiology and pharmacology at the University of Georgia School of Medicine in Augusta and the University and Bellevue Hospital Medical College in New York; died in the Providence Hospital Nov. 11, 1947, aged 56, of coronary thrombosis.

James Wilbur Shankland, St. Louis; St. Louis University School of Medicine, 1904; served during World War I; formerly city hospital commissioner; at one time on the staffs of the Missouri Baptist and St. John's hospitals; died Nov. 7, 1947, aged 80, of heart disease.

Ernst Simmel, Los Angeles; Universität Rostock Medizinische Fakultät, Rostock, Mecklenburg, Germany, 1908; member of the American Psychoanalytic Association; honorary president of the Los Angeles Psychoanalytic Society; died Nov. 11, 1947, aged 65, of heart disease.

Minabel Snow, Brecksville, Ohio; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1899; died recently, aged 82, of pneumonia.

John Howard Snyder, Sunbury, Pa.; Illinois Medical College, Chicago, 1902; medical examiner for the Pennsylvania Railroad; died in Sacred Heart Hospital, Allentown, recently, aged 73, of myocardial infarction.

Dallas Southard & Stamford, Texas; University of Tennessee College of Medicine, Memphis, 1911; served in France during World War I; affiliated with Stamford Sanitarium; died in Pleasant Hill recently, aged 65, of coronary thrombosis.

Erwin Straehley & Cincinnati; Medical College of Ohio, Cincinnati, 1889; affiliated with the Christ and Deaconess hospitals; at one time assistant health officer; for many years member of the board of trustees of the University of Cincinnati; died in Good Samaritan Hospital Nov. 6, 1947, aged 79, of carcinoma of the rectosigmoid.

Joseph Toal & Ridgefield, N. J.; Syracuse University College of Medicine, 1927; affiliated with the Englewood Hospital, where he died recently, aged 56, of coronary thrombosis.

Ansel Harry Tulupan, Chicago; Loyola University School of Medicine, Chicago, 1925; died Nov. 27, 1947, aged 47, of coronary thrombosis.

Arthur Henry Weis, Chicago; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1901; served during World War II; on the staff of the Columbus Memorial Hospital; health editor of the *Abendpost*; died in Mount Sinai Hospital Nov. 10, 1947, aged 74, of virus pneumonia.

William Whitridge Williams & Denver; Johns Hopkins University School of Medicine, Baltimore, 1899; specialist certified by the American Board of Pathology; served as a member of the state board of medical examiners, of which he had been secretary-treasurer; affiliated with the Denver General, City and County and St. Luke's hospitals; died recently, aged 71.

Preston Ezekiel Wolfe, Abingdon, Va.; University of the City of New York Medical Department, New York, 1890; died recently, aged 84, of cerebral anemia and arteriosclerosis.

Robert Henry Wymer & Altoona, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1921; during World War I served in the student army training corps; an examining physician for the Selective Service System during World War II; member of the staff of the Mercy Hospital; died recently, aged 49, of coronary thrombosis.

DIED WHILE IN MILITARY SERVICE

John Charles Gaffney Jr. & Assistant Surgeon, Lieutenant (jg) U. S. Navy, Du Bois, Pa.; Loyola University School of Medicine, Chicago, 1943; began active duty in the U. S. Navy in May 1943, interned at the Naval Hospital in Key West, Fla.; died in a typhoon in the Asiatic area Dec. 18, 1944, aged 28.

John Richard Siddall, Riverton, N. J.; Jefferson Medical College of Philadelphia, 1937; member of the American Medical Association; interned at the Cooper Hospital in Camden; served a residency at the Sloane Hospital for Women in New York; began active duty as a first lieutenant in the medical corps, Army of the United States, in May 1942; promoted to captain; died on Ascension Island May 10, 1945, aged 34, of asphyxia and third degree burns received in a plane crash.

Prevention of Meningitis Following Spinal Puncture

The Public Health Laboratory Service and the London Sector Pathologists' Committee has issued a memorandum on the avoidance of the meningitis which results from inoculation into the spinal canal of microbes in the operation of withdrawal of cerebrospinal fluid or in the induction of spinal anesthesia. The organisms most frequently incriminated are *Pseudomonas aeruginosa* and related organisms which can multiply in water at room temperature. Less frequently staphylococci and other skin contaminants are responsible. The sources of contamination are (1) apparatus insufficiently sterilized or contaminated during use; (2) so-called sterile water or saline solution used to rinse the apparatus; (3) hands of the operator or his assistants; (4) skin of the patient, and (5) anesthetic, antibiotic or other solutions.

For prevention the ideal would be to adopt the full antiseptic ritual of a surgical operation. But in many cases time and place render this impossible. The following measures are therefore recommended as practical in nearly all circumstances. If facilities are available, all apparatus, including manometer, should be enclosed within suitable containers and sterilized either by autoclaving at 15 to 20 pounds (6.8 to 9.1 Kg.) pressure for twenty minutes or by dry heat at 160 C. for an hour. The complete outfit can then be held ready for use at any time. If dry heat is used the rubber tubing of the manometer should be sterilized by boiling. For syringes and needles dry heat is preferable but ordinarily necessitates all-glass syringes. If autoclaving or sterilization by dry heat cannot be employed, all apparatus should be sterilized immediately before the operation by boiling for five minutes, preferably in distilled water. A sterilizer with a perforated lift-up tray should be used. At the end of the boiling the tray is removed, placed in the inverted lid, covered with a sterile towel and left to cool. In emergencies a perfectly clean saucepan with a lid can be used. After boiling the water should be drained off and the saucepan left with the lid on until cool. Chemical disinfection, such as soaking in alcohol, should not be used.

The operator should scrub up as for a major operation, or should don dry sterile gloves. If gloves are not available his hands should be dry before he handles any apparatus. This may be accomplished by rinsing with industrial alcohol and/or drying with a sterile towel. Where needle and syringe have to be assembled, the needle should be handled with sterile forceps. From this point onward the operator should touch nothing except the sterile instruments and the skin of the patient. The trochar when withdrawn should be laid on a sterile towel; otherwise it may infect the spinal fluid if introduced again to clear the needle. The skin of the patient should be thoroughly washed with soap and warm water, followed by thorough swabbing with tincture of iodine or 70 to 90 per cent alcohol.

Sir Bernard Spilsbury

Sir Bernard Spilsbury, who for thirty years was the foremost medicolegal pathologist and was employed by the police to investigate the cause of death in all the notorious crimes, was found dying in his laboratory at University College, London. The room was filled with illuminating gas. He had reached the age of 70 and had been in ill health for some time. The coroner's verdict was that he had turned on the gas while his mind was deranged. He retired from his position as government pathologist in 1934 but had continued to work as honorary pathologist and to lecture. His position was unique. Between

the two wars there was hardly a case in which the painstaking collection of evidence was required for the conviction of a murderer in which he was not employed. A striking example was the sensational "Brides in the Bath" case. A man and his newly wedded wife were living in lodgings. In the morning while she was taking a bath he went out, according to his own account, to buy fish. On his return he raised an alarm in the house because, according to his account, he had found his wife collapsed in the bath. She was drowned, and at the inquest his version was accepted and it was supposed that the woman had fainted in the tub and then was drowned. But when a second wife and later a third wife died in the same way, suspicion was aroused and Spilsbury was called in by the police. He came to the conclusion that the women had been murdered by the husband's seizing their feet and suddenly raising them, which would drag their heads under the water. They would be drowned without being able to cry out and alarm the other occupants of the house. To test his hypothesis Spilsbury experimented with a nurse, who, clad in bathing suit, entered a bath full of water. Spilsbury suddenly lifted her feet. She nearly died and had to be revived by artificial respiration. The husband was convicted of murder. No such method of murder was ever known before or since this crime.

Another notorious case was that of "Dr." Crippen. His wife had disappeared, and human remains which could not be identified were found in the cellar of Crippen's house in London. A fraction of a grain of scopolamine hydrobromide was isolated from the remains, and he was convicted of murder.

PALESTINE

JERUSALEM, Dec. 15, 1947.

The Rh Factor Among Jewish Communities

In a study on the Rh factor, Gurevitch, Sadowsky, Brzezinski and Polishuk of the Rothschild Hadassah University Hospital found great variations in the incidence of the Rh factor among the different Jewish communities in Jerusalem. Among 1,913 women examined, only 9.6 per cent were Rh negative. Among 12,645 deliveries during a period of eight years only 6 cases of erythroblastosis fetalis were observed. On the basis of these figures the rate of erythroblastosis fetalis among Rh-negative women was 1:210, which compares with a rate of 1:25 to 1:50 reported elsewhere. Of special interest may be the low rate of Rh-negative women found in the Yemenite and Kurdish-Persian communities. Of 44 Yemenite women examined, only 1 was found to be Rh negative, i. e., 2.3 per cent; an even lower rate of 1.5 per cent Rh-negative persons was found among 203 Kurdish-Persian women. These two groups are characterized by their segregated mode of life, intermarriage is rare among them. It is significant that not a single case of erythroblastosis fetalis has been observed among 310 deliveries in Yemenite Jewesses and 1,739 deliveries among Kurdish-Persian Jewesses in the obstetric department of this hospital during the last six years.

In a study of the Rh factor among women suffering from habitual abortion, toxemia of pregnancy, stillbirths and prematurity, the rate of Rh-negative women was similar to that observed in the population at random. In a group of 22 women with obstetric histories suggestive of Rh incompatibility only 3 Rh-negative patients have been found. No case of erythroblastosis fetalis and no signs of isoimmunization in the mothers have been observed in this group.

A detailed study was made in a group of 32 Rh-negative multiparas with obstetric histories of six to fourteen pregnancies. The total of pregnancies in this group was two hundred and seventy-nine. All the husbands except three were homozygous. No case of erythroblastosis fetalis and no signs of isoimmunization in the mothers have occurred in this group.

Allergic Warm Season Conjunctivitis

Conjunctivitis vernalis was the designation given to conjunctivitis appearing periodically in Palestine and reported every year. During the Congress of the Jewish Medical Association in 1944 M. J. Gutmann reported on this disease (*Acta med. orient.* 4:150 [May] 1945), calling it an allergic warm season conjunctivitis, as it appears during the months from February to November, in other words during the warm season, and practically disappears with the beginning of rain. The cause of this conjunctivitis is allergic; usually there is a chronic infection with a secondary fungous allergy. The most common fungi are of the following families: Alternaria, Hormodendrum, Cladosporium, Penicillium, Aspergillus and Monilia. The disease usually attacks young persons. Girls are apparently less susceptible than boys. Forty-five per cent of all patients were from 5 to 15 years of age.

The treatment primarily is aimed at removing the focus of infection and desensitizing the patients with a mixed extract of various molds and bacteria. Within six months—sometimes only after one to two years—two thirds of the patients could be freed of their symptoms. The therapy, however, is not entirely reliable. Gutmann stated that there are still many unsolved problems in connection with allergic warm season conjunctivitis.

In a paper just published (*Acta med. orient.* 6:167 [May] 1947) Gutmann points out that riboflavin given in 5 mg. injections daily proved particularly effective in influencing the inflammation and itching of the eyes. He compares the effect of riboflavin with that of epinephrine in an attack of asthma. The desired effect was reached ten to thirty minutes after the injection of riboflavin and could be maintained for twelve to fourteen hours. The administration of riboflavin in tablet form did not produce relief, but fresh yeast often proved to be successful. Symptoms of riboflavin deficiency could not be found.

TURKEY

(From Our Regular Correspondent)

ANKARA, Dec. 22, 1947.

Aid to Egypt During the Recent Cholera Epidemic

The sudden outbreak of cholera in Egypt during the last week of September 1947 placed Turkey in a difficult position. For the first time in eight years Turkish pilgrims were on their way to Mecca, and many others were in the midst of preparations to procure their passports. Moreover, the eve before "Kurban Bairam" was on a Friday, which naturally made the pilgrimage all the more desirous. Almost 8,000 Mohammedans from Turkey alone had decided to make the pilgrimage this year.

Turkey had not had any cholera for years, and all the anti-cholera vaccine on hand had been sent during the war to China, where it was urgently needed. At the Refik Saydam Institute (Central Institute of Hygiene) the preparation of anticholera vaccine was at once undertaken. The pilgrims and the inhabitants along the coast and at the southern borderline of Syria were vaccinated, and during the first week of October a physician, two trained nurses and four sanitary inspectors, equipped with vaccine for 500,000 persons, left Ankara for Egypt by air. Vaccine sufficient for 200,000 persons was forwarded soon afterward to Syria. The expedition is still working in Egypt in localities indicated by the Egyptian government.

Obviously, with cholera in Egypt, the scourge might easily find its way into Turkey. The Ministry of Health at once organized a cholera prevention board with representatives from the Ministry of National Defense, the Ministry of Communication and the Ministry of the Interior meeting every other day to get first hand information concerning the epidemic in Egypt and the state of health of the Turkish pilgrims. As a precautionary measure the work at the Central Institute of Hygiene proceeded on a twenty-four hour schedule to produce a sufficient quantity of immediately available vaccine. Vaccination teams

were organized to work all through the night, and all personnel on land, sea and air transportation systems, the whole population of the coastline provinces and all tradespeople handling food were immediately vaccinated. Measures were taken to insure the return of the pilgrims by a route other than Egypt and likewise that those returning by air alight only at the Istanbul landing field. Passenger boats were sent from Istanbul and Smyrna to the ports of Cidda Jidda and Beirut with the strictest order to take on no other passengers than Turkish pilgrims arriving there by land. At the Smyrna and Istanbul ports the returning pilgrims were quarantined, vaccinated and searched for carriers. All food that the pilgrims brought with them, even the water from the holy well in Mecca and the dates, was destroyed and special emphasis was given to disinfection of means of transportation, clothing and other possessions of the pilgrims and to the destruction of noxious insects or vermin with DDT. Through articles in the daily papers and radio talks the public was enlightened as to the nature of cholera; films were shown, posters and leaflets were distributed.

Great vigilance was necessary, and drastic measures had to be taken by the Nusaybin and Islahiye health authorities to prevent the scourge from coming in by these southern Syrian gates, for it was reported that pilgrims attempted to cross the border clandestinely in railway trains, automobiles, omnibuses, wagons, on horseback and on foot.

To insure a plentiful supply of anticholera vaccine the Ministry of Health set aside two more laboratories for its production, one in Istanbul and one in Smyrna. This made it possible to meet the Turkish needs and come to the assistance of Egypt, Syria and other countries.

Through the interest people are now taking in regard to matters of health as a result of education and health propaganda, and through the health organization of the Turkish republic, it has been possible to avert this terrible scourge and assist neighboring countries as advocated in the constitution of the World Health Organization of the United Nations.

"Paludrine" and "Quipenyl" Therapy in Malaria

Results concerning the treatment of malaria with the new remedies "paludrine hydrochloride" (chlorguanide hydrochloride) and "quipenyl" at the Ministry of Health's Adana Malaria Institute have been published by Dr. Celal Gokberk, chief of the institute's laboratory. Neither single dose nor daily continual doses of 0.75 or 1 Gm. of "paludrine" for adults have produced toxic effects. Children above 8 years of age were given 0.1 Gm. twice daily; the same dose was also given to a delicate child aged 3 years and to a child aged 12 years with no untoward results. The blood chemical formula in 11 patients revealed no abnormal conditions; after treatment a 9 per cent reticulocytic crisis was found in 1 patient, 7 per cent in another. Urinalysis was normal on admission and on discharge. In 10 ambulant cases of benign tertian malaria (due to *Plasmodium vivax*) a single dose of two to three tablets was given and patients recovered within a month, but after a short interval there were some recurrences and a single tablet then had no effect. In the malignant form of tertian malaria (due to *Plasmodium falciparum*) "paludrine" was not satisfactory; parasites in the blood diminished greatly and a second attack was forestalled, but in from seven to ten days there were recurrences. At the institute hospital in 11 of 12 cases of benign malaria the remedy was effective in preventing a second attack; in the 1 case in which the results were unsatisfactory, a great many parasites were present in the blood. In the morning and evening blood examination of 8 patients the parasites had completely disappeared within three days, in 5 patients within two days. Splenic punctures were performed in 2 cases, revealing the presence of parasites on the fourth day in 1 case, while the other was negative. In 1 case of *vivax* and *falciparum* (mixed) malaria there was a second attack which came to a halt on the third day. In 9 of

13 cases of tertian malaria due to *P. falciparum* second attacks occurred. In 2 of the other 4 cases the parasites in the circulating blood had disappeared on the second day, in 3 on the seventh and in 4 on the fourth day. How far the new remedy is effective evidently depends on the concentration of parasites in the blood. In 1 of 3 patients on whom a splenic puncture was performed the parasites disappeared on the sixth day and in the other 2 on the fourth day. In 2 cases in which a bone marrow puncture was performed, the parasites had disappeared on the fourth day. For examination of the blood the drop and the smear methods were employed, using the original Giemsa solution for staining. During a second attack of malaria tropica the chromatin rings had taken the dye only slightly, and the widening and disappearance of the chromatin granules was observed. The protoplasm had also taken the dye only slightly, and patches devoid of chromatin were visible. The formation of new rings from degenerated adult parasites in benign tertian malaria has not been observed. Blood examination of patients under treatment were made twice and three times during twenty-four hours, and during from three to seven days. In malaria tropica "paludrine" had no effect on schizonts or gametes.

"Quipenyl," a malaria remedy on a "plasmochin" (pamaquine naphthoate) basis, was also given a trial in 2 cases due to *P. vivax*, 2 cases due to *P. falciparum* and 1 case due to mixed tertiana-tropica infection. Three times daily these patients were given a 0.01 Gm. tablet of the drug, resulting in the disappearance of the gametes. Though in the chronic cases the gametes disappeared in the blood stream it was not possible to prevent the formation of new gametes, which were again made to disappear with "quipenyl." In 3 of the 5 cases, gametes disappeared on the third day; in 1 chronic case they disappeared on the fourth day but reappeared on the fifth. This patient was again given "quipenyl," and on the eighth day the blood was completely free from gametes. It was observed that the protoplasm and chromatin granules had taken the dye only slightly and that the remedy had no effect on pigmentation.

BUENOS AIRES

Jan. 10, 1948.

The Galli-Mainini Pregnancy Test

At the Congress of Obstetrics and Gynecology of the Rio de la Plata, in Buenos Aires, Dr. Carlos Galli-Mainini communicated further important data on his new test for pregnancy (*THE JOURNAL*, Oct. 11, 1947, p. 374). The basis of the test is the phenomenon of liberation and migration of spermatozoa of the toad, a direct effect of the administration of gonadotropin. The subcutaneous injection of 10 cc. of urine of a pregnant woman into the lymphatic sac provokes, due to its content of chorionic gonadotropin, the liberation of spermatozoa which in the adult toad normally are fixed at the Sertoli cells. The already free spermatozoa pass through the vas deferens and certain renal glomeruli and appear in the urine, where they are then found as described in *THE JOURNAL*, Aug. 2, 1947, page 1196.

The male toad is smaller than the female, its color is darker and more uniform, its skin more rugged, its forearm thicker; it croaks when taken by the sides; it has a dark brown pigmentation on the inner side of the thumb and has the embrace reflex. It is easy to handle and to keep, without alimentation, in a pool for months; it only needs a humid surrounding.

Factors which are important for the reaction include the weight of the toad, which should not be under 100 Gm. The minimum dose is apparently about 40 units of chorionic gonadotropin; a greater quantity is necessary if serum gonadotropin is used. The division into fractions of a dose which is insufficient when given all at once does not increase the capacity of

the reaction. Low temperatures delay the reaction, while darkness apparently is favorable.

The test is positive with chorionic and serum gonadotropin, with hypophysis of the toad, the rat and the rabbit, and also with the bovine follicle-stimulating hormone. It is negative with the urine of normal men and women, children and aged persons; with gynecologic or endocrine disorders; with estrogens, progesterone, testosterone, thyroxin, desoxicorticosterone, beta-hypophamine ("pitressin"), epinephrine, adrenocorticotropin, corticotropin, prolactin; hypophysis of cattle, dog and pig, of *Crotalus terrificus*; with serum and urine of pregnant sheep, cow, mare or hog; with suspension of tissue of liver, kidney, adrenal gland, spleen, heart, gastrointestinal tract, muscles, intermediate lobe of hypophysis; with zinc sulfate, methylene blue, acetylcholine and copper acetate.

The results obtained from 1,354 tests in the first four months of pregnancy were 99.56 per cent correct with not one false positive result. The toxicity of the female urine for the toad is very low (0.95 per cent mortality). Among 281 tests made simultaneously with the Friedman test, 19 results did not coincide. In 2 of them it could not be established if the toad or the rabbit proved correct; in 2 others the rabbit was correct, and in 15 others, the toad. Among 123 women pregnant from six to nine months the percentage of positive results was less. The positivity was better with urine than with serum.

In quantitative investigations it was found that the test was still positive in some cases with as little as 0.125 cc. of urine, while in other cases as much as 4 cc. was necessary. Other quantitative studies showed that the urine lost little of its gonadotropic potency at normal temperature until after ten days.

Of 385 positive tests, 88 per cent could be determined within two hours.

With respect to urine, the test is only positive with urine of pregnant women or with mole (2 cases) or chorionepithelioma (2 cases).

The result is always clearly positive or negative, through the presence or absence of spermatozoa. The technic is simple, without previous preparation of patient or urine. Special microscopic technic is not necessary, and differentiation of the spermatozoa is easy. The test animals are inexpensive, do not need special attention and can be used repeatedly.

In the discussion the eleven communications on this subject confirmed the statements of Dr. Galli-Mainini. They referred to experiences with 150 to 470 tests carried on by each author.

Orthopedic Traction on the Skeleton

Dr. Carlos E. Ottolenghi, associate professor of orthopedic surgery, Faculty of Medicine of Buenos Aires, has completed an investigation for which he has just received the prize which is annually awarded by the Argentine Society of Surgeons. Ottolenghi studied in dogs and rabbits, as well as clinically, the tolerance of the organism for iron wire and traction, particularly the reactions of the tissues, the histopathologic changes, the technic of application and the resistance of different kinds which the wire has to overcome, the direction of the traction powers and the application of wire in children. Infection and exaggerated traction are the most important dangers of traction on the skeleton. He prefers to put the wires in tension according to Kirschner's technic without using the nails of Steinmann.

Brief Items

The first Argentine Congress of Bronchoesophagology was held under the honorary chairmanship of Professor Chevalier L. Jackson of Philadelphia, who gave courses in Buenos Aires and in Córdoba at the invitation of the corresponding Argentine societies. Argentine chairman of the meeting was Dr. Alvaro Bence. The subjects treated were: diagnostic and therapeutic indications of bronchology and esophagology, hospital services of oral endoscopy and oral endoscopy in children.

MEDICAL CONDITIONS IN ALASKA

To the Editor:—The special article on Medical Conditions in Alaska in *THE JOURNAL*, Oct. 25, 1947, page 500, terminated with a number of recommendations to treat, protect and improve the health of the people of Alaska.

Between 1942 and 1946 I was physician-in-charge at the Point Barrow Hospital and was responsible for the health of the people along the Arctic shore. In 1943 the Kotzebue Hospital and the district it covered was also assigned to me. I then traveled between the two hospitals and had the opportunity to visit every Eskimo village in the two districts more than once during layovers and field trips.

The Special Investigating Committee was accurately informed that in most of the native villages at least 25 per cent of the people had active tuberculosis at any one time. The number of active cases in the territory was estimated at a minimum of 4,000. They recommended that a minimum of one thousand beds be made available for the isolation and treatment of patients with tuberculosis. They suggested immunization with BCG vaccine to reduce the incidence of tuberculosis. However, they made no further recommendations for the care and treatment of the remaining 3,000 persons with active cases of the disease.

I had hoped that they would follow up their description of the congestion in the native homes, which they considered one of the main causes for the tremendous incidence of tuberculosis, with a suitable recommendation. I believe that there is a solution to that problem if sufficient interest and attention could be focused on it.

The best in Eskimo culture, in addition to their fine manners, is exemplified by their hand-sewn fur garments and skin clothing and the making of skin-covered boats. Their homes, however, are simple and designed primarily to provide shelter—there is no privacy or convenience. These are permanent structures. The Eskimo is not a nomad. Permanent villages are established at the best hunting and fishing sites. The Eskimo igloo is really a sod house—seldom larger than 10 by 12 by 6 feet (305 by 366 by 183 cm.). There is generally a short, low, entry way used for storage and the shelter of young or weak dogs in the winter. Light is conveyed through a skylight consisting of a wooden frame 2 feet (61 cm.) square, supporting several bowed rods which project outward and on which sewed strips of walrus gut are stretched. There is a small air vent 2 by 6 inches (5 by 15 cm.) leading through the sod roof. The sod house is built around a frame of wooden posts and beams or whale ribs. Heat is furnished by a small oven, fabricated from a discarded oil drum, or a small iron stove. In the villages in which there has been a strong influence exerted by white men, whalers, traders and gold miners, most of the sod houses have been replaced by the more modern wooden frame house. In a country where the temperature during January and February falls to 45 to 50 degrees below zero, and the velocity of the wind may rise to 50 to 60 miles per hour and continue for days, no more preposterous type of home could have been devised. It proves how easily the Eskimo is attracted to white men's ways and how willing he is to accept them.

At Point Barrow, a community of close to six hundred persons, there is only one sod house which is occupied. All other fifty-five houses are wooden frame structures. Except for about six houses which are larger, nearly all measure 10 feet (305 cm.) wide, 13 feet (299 cm.) long and 7 feet (213 cm.) high. The inner and outer walls are 4 inches (10 cm.) apart. In the spring of 1943, with the aid of a native assistant, I had measured every dwelling at Point Barrow and enumerated the number of inhabitants in each. In some there were as many as

fourteen persons. The average was ten persons to a house. The records of this survey are on file at the Point Barrow Hospital. We listed 80 known cases of tuberculosis with active primary and secondary types of infection.

The reason for the congestion was the lack of fuel and food. There was insufficient driftwood; "outside" coal cost \$70 per ton; a week's supply of pitch, secured from oil seepages located at Cape Simpson 60 miles (97 kilometers) to the east, required a dog team of at least seven dogs; a hunter's time and effort for five to seven days, and food for himself and the dogs. These could rarely be spared from the more urgent pursuit of hunting. An inadequate supply of pitch from Cape Simpson and coal from outcroppings at Wainwright 100 miles (161 kilometers) to the west was secured during the summer months, when the ice receded from the shore and permitted the whale boats to motor to Cape Simpson and Wainwright. There was no money for the purchase of "outside" coal except by a few more provident families.

Similar conditions prevailed up and down the Arctic coast. At Wainwright, where outcroppings of coal existed, the wooden frame houses and the sod igloos were slightly larger and were inhabited by fewer persons. But at Point Lay, Point Hope, Kivilina, Shishmaref, Deering, Wales, and Kotzebue, conditions were similar to that of Point Barrow. In these villages, except for Kotzebue, sod igloos predominated.

The pioneers who settled the Western Plain states in the last century lived in large, relatively comfortable sod houses—far better than those the Eskimos occupy today. In the Arctic there are millions of acres of tundra out of which to build large commodious sod houses with privacy and with some conveniences.

The Eskimos of the Arctic have entered into a new phase of cultural relations with the white man. Whereas prior to the war they were isolated, their only contact with the outside world being through the government teachers, missionaries, Army Signal Corps operators, the annual freight boat and the pilot of the occasional mail plane, today they are encompassed by the men and machines of the United States endeavoring to build Alaska into a military base. The hunting economy is rapidly being displaced by easier and more assured methods of earning money and purchasing the needed supplies at the trader's store.

The Eskimo has changed his mode of life but not his dwelling. His manual skill, reliability, self effacing manner and congenial nature have made him a much sought-after employee by the Navy oil contractors at Point Barrow, the Alaska Road Commission, the Army engineers, the U. S. Weather Bureau and the Civil Aeronautic Authority. The Eskimos have the money but lack the know-how.

The basic material is underfoot. The Eskimo has the money to purchase the additional materials and fuel. I believe that a capable architect could devise a model modern Eskimo home which would provide several rooms with thick sod walls, privacy and sanitary conveniences, eliminating congestion and reducing the chance for the dissemination of tuberculosis. If this is done, I believe that the care of large numbers of patients with active tuberculosis who will not secure admission to the projected sanatoriums may then be provided at their homes. An effort to solve the problem of the 3,000 remaining cases of active tuberculosis will then have been made.

EDWARD D. SEINFELD, M.D., Middletown, Conn.

To the Editor:—The special article in *THE JOURNAL* of Oct. 25, 1947, on medical conditions in Alaska contained two statistical items on which further information would be appreciated.

1. The death rate from tuberculosis is quoted as being 359.1 per hundred thousand for 1945-1946. From that figure it is deduced that the total number of cases of open pulmonary

Streptomycin in Meningitis.—According to Paine and associates streptomycin has been used in the treatment of 27 cases of meningitis at the Boston City Hospital. There was 1 death among 16 cases due to *Hemophilus influenzae* and 2 deaths among 8 cases due to other gram-negative bacilli. The deaths occurred in 2 patients in whom treatment with streptomycin was begun late in the disease. The third fatality was associated with the development of a streptomycin resistant strain of *Pseudomonas aeruginosa* during treatment. Two of 3 patients with tuberculous meningitis are living, and their disease appears to be arrested. The results in these and similar cases reported by others seem to justify the following conclusions: 1. Streptomycin is the only agent now available which may arrest the progress of tuberculous meningitis. 2. Streptomycin is the most effective single agent in the treatment of meningitis due to gram-negative bacilli, including *H. influenzae*. The authors note 8 additional cases of meningitis treated with streptomycin since the completion of this report. They include additional cases caused by *H. influenzae*, by *Escherichia coli* communis and *Klebsiella pneumoniae*, also additional cases of tuberculous meningitis. Two of these cases, 1 caused by an organism of the coli group and 1 caused by *K. pneumoniae*, terminated in death.

Pleuropulmonary Tularemia.—Morgan presents histories of selected cases from the rebuilt University Hospital material and reports 15 additional cases of pleuropulmonary tularemia treated with streptomycin after Veterans Administration hospitals. The recognition of pleuropulmonary involvement does not present a problem when the typical primary ulcer and regional lymphadenitis are present. In the absence of these lesions the diagnosis is obscure. The author found that more than 10 per cent of pleuropulmonary tularemia infections presented themselves as pneumonia of unknown etiology. The diagnosis is seriously handicapped when the primary infection is considered and the patient is employed, for the demonstration of agglutinins by mouse inoculation is not possible. The agglutinins disappear after the second or third week of illness. Patients with severe

tions may die before an accurate diagnosis can be established by these methods. Streptomycin has been found to cure pleuropulmonary tularemia, which in the prestreptomycin era had a mortality rate of from 20 to 40 per cent. A therapeutic trial with streptomycin may save life in an infection which sometimes kills before a diagnosis can be made. Administration of streptomycin does not inhibit the subsequent appearance of diagnostic agglutinins. A therapeutic trial with streptomycin is indicated in critically ill patients suspected of having severe primary atypical pneumonia or other forms of virus pneumonia, when the illness is of less than two weeks' duration and when it occurs in a region where tularemia is endemic.

Nitrogen Mustard in Hodgkin's Disease, Lymphosarcoma and Leukemia.—The nitrogen mustards (beta-chloroethylamines) differ from the wartime mustard gas only in that nitrogen replaces sulfur. The biologic effects of the nitrogen mustards are almost identical with those of radiant energy. Wintrobe and his associates have used methyl bis (beta-chloroethyl) amine hydrochloride (nitrogen mustard) in 28 patients with Hodgkin's disease, 11 with lymphosarcoma, 26 with leukemia and 12 with miscellaneous diseases. An infusion of isotonic sodium chloride solution is started, and its smooth running into the vein is assured. To 10 mg. of dry white crystalline hydrochloride salt of the mustard is added 10 cc. of sterile isotonic sodium chloride solution. The salt dissolves promptly, and the calculated dose of solution is withdrawn into a sterile syringe. This is administered immediately by injecting it through the rubber tubing of the saline infusion. A salutary effect on lymph nodes, fever, splenomegaly and various clinical symptoms, similar to that produced by roentgen irradiation, was observed in many patients with Hodgkin's disease, lymphosarcoma and leukemia. Nitrogen mustard has produced remissions in several patients with Hodgkin's disease who were considered to be roentgen resistant. Toxic manifestations of nausea and vomiting were observed in most patients. Nitrogen mustard therapy almost invariably resulted in a decrease in leukocyte count with lymphocytopenia and granulocytopenia. This was often accompanied by a decrease in red cells and platelets. Subsequent to the initial decrease in blood elements, an increase in red cells even with complete disappearance of anemia was the result in those patients who responded favorably. Leukopenia and thrombocytopenia likewise disappeared. Nitrogen mustard offers certain advantages as compared with roentgen irradiation. These include ease of administration, effectiveness, at times, in patients resistant to roentgen therapy, and, rarely, a better tolerance for nitrogen mustard than for irradiation. Unfortunately, however, nitrogen mustard, like irradiation, has been ineffective in many cases.

a lowered voltage output. Electroencephalographic abnormalities were not noted in guinea pigs given either intracerebral or peripheral injections of murine poliomyelitis virus in the presence or in the absence of paralytic symptoms. Of 17 patients convalescent from poliomyelitis, all of whom had severe residual paralysis, 2 exhibited definite electroencephalographic abnormality and 5 showed a borderline disturbance. The remaining 10 patients had normal electroencephalograms.

Mineral Oil, a Health Hazard.—Browne points out that in spite of warnings that the ingestion of mineral oil has a deleterious effect on human beings, many persons have continued to take it by mouth, in the belief that its only actions are those of softening the feces and lubricating the intestines. Notable among the constant users of mineral oil are pregnant women and women wishing a substitute for vegetable oils in reducing diets. During the war, because of the shortage of oils of vegetable origin, salad dressings made with mineral oil instead of vegetable oils became more numerous on market shelves, and new uses for it were found, such as the preparation of popcorn, salted nuts, doughnuts, croquettes and potato chips. Mineral oil interferes with the absorption of vitamins and minerals, with normal physiologic processes of the intestinal tract and with anal hygiene. Animal experiments have shown that the belief that mineral oil is not absorbed by the intestines is untenable. Physicians not only should not recommend mineral oil but should warn patients against its use. Only in this way will its consumption be reduced. More consideration should be given to the causes of constipation and their removal.

Tularemia in Illinois.—According to McDaniels, 95 per cent of the cases of tularemia in Illinois are acquired by skinning or cleaning wild rabbits. During the ten years ending with 1945, there was an average of about 185 reported cases per year in Illinois. However, the number of cases has ranged from 55 to 485. Cook County, with over half the population of the entire state, reports about 10 per cent of the cases. Wild rabbits sold in the markets of Chicago and suburbs come principally from Missouri, Iowa, Illinois, Kansas and the Dakotas. Many of the Chicago cases among market men, housewives, etc., are

attributable to these rabbits. Other Chicago patients received their infection while hunting rabbits in southern counties of Illinois and in neighboring states. About 85 per cent of all reported cases have been ulceroglandular infections. Approximately 10 per cent have been reported as being of the typhoidal variety. The remaining 5 per cent are made up of oculoglandular and glandular infections. In the typhoidal type of tularemia the incubation period tends to be longer by about one week than in the ulceroglandular cases. The shortest duration was sixteen days, the longest three hundred and sixty days. The most effective treatment of tularemia consists of the administration of streptomycin in adequate amounts. The prophylactic measures recommended by the author include among others the use of rubber gloves by persons engaged in dressing wild rabbits or in performing necropsies on laboratory animals; employment of immune persons for dressing wild rabbits or conducting laboratory experiments; thorough cooking of meat of wild rabbits, and avoidance of raw drinking water in areas where the disease prevails among wild animals.

Transmission of Epidemic Gastroenteritis.—Gordon and his associates say that numerous outbreaks of gastroenteritis occurred in New York state institutions during the fall and winter of 1946-1947. The disease was characterized by a sudden onset, by profuse diarrhea, usually accompanied by vomiting, and by a lack of fever. Symptoms ordinarily persisted for about three days. Bacteriologic examinations failed to reveal agents known to cause enteric disease, and postmortem investigations failed to indicate the nature of the etiologic agent. A search was made for a nonbacterial pathogen. Since preliminary animal experiments were unsuccessful, human volunteers were utilized. The illness was reproduced and transmitted in series in volunteers, and the responsible agent was shown to be filterable. Oral administration of stool suspensions or throat washings induced the disease, but inhalation of nebulized throat washings did not. Volunteers who were fed material from the third embryonated egg passage likewise remained asymptomatic.

Pleuropulmonary Tularemia.—Morgan presents histories of selected cases from the Vanderbilt University Hospital material and reports 15 additional cases of pleuropulmonary tularemia treated with streptomycin in Veterans Administration hospitals. The recognition of tularemic infection with or without pulmonary involvement does not pose a problem when the typical primary ulcer and regional buboes are present. In the absence of these lesions the clinical picture is obscure. The author found that more than half of the pleuropulmonary tularemic infections presented themselves as instances of obscure pulmonary infections or masqueraded as cases of primary atypical pneumonia of unknown etiology. In such circumstances the clinician is seriously handicapped even when the possibility of tularemic infection is considered and diagnostic tests for its presence are employed, for the demonstration of *Pasteurella tularensis* in culture or by mouse inoculation is time consuming and dangerous, and diagnostic agglutinins do not appear in the patient's blood until the end of the second or during the third week of infection. Thus patients with severe tularemic infec-

tions may die before an accurate diagnosis can be by these methods. Streptomycin has been found to pulmonary tularemia, which in the prestreptomycin mortality rate of from 20 to 40 per cent. A therapy with streptomycin may save life in an infection which kills before a diagnosis can be made. Administration of streptomycin does not inhibit the subsequent appearance of agglutinins. A therapeutic trial with streptomycin in critically ill patients suspected of having severe atypical pneumonia or other forms of virus pneumonia the illness is of less than two weeks' duration and when in a region where tularemia is endemic.

Nitrogen Mustard in Hodgkin's Disease, Lymphosarcoma and Leukemia.—The nitrogen mustards (nitrogen ethylamines) differ from the wartime mustard gas (mustard) in that nitrogen replaces sulfur. The biologic effects of the nitrogen mustards are almost identical with those of the mustard gas. Wintrobe and his associates have used methyl bis (2-chloroethyl) amine hydrochloride (nitrogen mustard) in the treatment of Hodgkin's disease, 11 with lymphosarcoma, 12 with leukemia and 12 with miscellaneous diseases. An isotonic sodium chloride solution is started, and when the patient is running into the vein is assured. To 10 mg. of crystalline hydrochloride salt of the mustard is added an equal volume of sterile isotonic sodium chloride solution. The solution is drawn up promptly, and the calculated dose of solution is withdrawn with a sterile syringe. This is administered immediately into the vein through the rubber tubing of the saline infusion. The effect on lymph nodes, fever, splenomegaly and various symptoms, similar to that produced by roentgen irradiation, is observed in many patients with Hodgkin's disease, lymphosarcoma and leukemia. Nitrogen mustard has produced remissions in several patients with Hodgkin's disease. It is considered to be roentgen resistant. Toxic manifestations of nausea and vomiting were observed in most patients. Mustard therapy almost invariably resulted in a decrease in leukocyte count with lymphocytopenia and granulocytopenia. This was often accompanied by a decrease in red blood cells and platelets. Subsequent to the initial decrease in blood counts, an increase in red cells even with complete disappearance of anemia was the result in those patients who responded. Leukopenia and thrombocytopenia likewise disappeared. Nitrogen mustard offers certain advantages as compared with roentgen irradiation. These include ease of administration, effectiveness at times, in patients resistant to roentgen therapy, and a better tolerance for nitrogen mustard than for roentgen. Ultimately, however, nitrogen mustard, like irradiation, proved ineffective in many cases.

Electroencephalogram in Poliomyelitis.—Pacella and associates studied electrophysiologic alterations of the brain during the course of poliomyelitis. Definite or electroencephalographic changes which might indicate electrocortical activity were not observed prior to the onset of fever or paralysis in monkeys given intracerebral injections of simian poliomyelitis virus. Abnormalities of the electroencephalogram appeared during the paralytic stage and became more conspicuous with the progression of the disease. The electroencephalographic changes consisted chiefly of a progressive increase of slow activity, disappearance of fast activity, a relative increase in the amount of fast activity.

a lowered voltage output. Electroencephalographic abnormalities were not noted in guinea pigs given either intracerebral or peripheral injections of murine poliomyelitis virus in the presence or in the absence of paralytic symptoms. Of 17 patients convalescent from poliomyelitis, all of whom had severe residual paralysis, 2 exhibited definite electroencephalographic abnormality and 5 showed a borderline disturbance. The remaining 10 patients had normal electroencephalograms.

Mineral Oil, a Health Hazard.—Browne points out that in spite of warnings that the ingestion of mineral oil has a deleterious effect on human beings, many persons have continued to take it by mouth, in the belief that its only actions are those of softening the feces and lubricating the intestines. Notable among the constant users of mineral oil are pregnant women and women wishing a substitute for vegetable oils in reducing diets. During the war, because of the shortage of oils of vegetable origin, salad dressings made with mineral oil instead of vegetable oils became more numerous on market shelves, and new uses for it were found, such as the preparation of popcorn, salted nuts, doughnuts, croquettes and potato chips. Mineral oil interferes with the absorption of vitamins and minerals, with normal physiologic processes of the intestinal tract and with anal hygiene. Animal experiments have shown that the belief that mineral oil is not absorbed by the intestines is untenable. Physicians not only should not recommend mineral oil but should warn patients against its use. Only in this way will its consumption be reduced. More consideration should be given to the causes of constipation and their removal.

Tularemia in Illinois.—According to McDaniels, 95 per cent of the cases of tularemia in Illinois are acquired by skinning or cleaning wild rabbits. During the ten years ending with 1945, there was an average of about 185 reported cases per year in Illinois. However, the number of cases has ranged from 55 to 485. Cook County, with over half the population of the entire state, reports about 10 per cent of the cases. Wild rabbits sold in the markets of Chicago and suburbs come principally from Missouri, Iowa, Illinois, Kansas and the Dakotas. Many of the Chicago cases among market men, housewives, etc., are

attributable to these rabbits. Other Chicago patients received their infection while hunting rabbits in southern counties of Illinois and in neighboring states. About 85 per cent of all reported cases have been ulceroglandular infections. Approximately 10 per cent have been reported as being of the typhoidal variety. The remaining 5 per cent are made up of oculoglandular and glandular infections. In the typhoidal type of tularemia the incubation period tends to be longer by about one week than in the ulceroglandular cases. The shortest duration was sixteen days, the longest three hundred and sixty days. The most effective treatment of tularemia consists of the administration of streptomycin in adequate amounts. The prophylactic measures recommended by the author include among others the use of rubber gloves by persons engaged in dressing wild rabbits or in performing necropsies on laboratory animals; employment of immune persons for dressing wild rabbits or conducting laboratory experiments; thorough cooking of meat of wild rabbits, and avoidance of raw drinking water in areas where the disease prevails among wild animals.

Transmission of Epidemic Gastroenteritis.—Gordon and his associates say that numerous outbreaks of gastroenteritis occurred in New York state institutions during the fall and winter of 1946-1947. The disease was characterized by a sudden onset, by profuse diarrhea, usually accompanied by vomiting, and by a lack of fever. Symptoms ordinarily persisted for about three days. Bacteriologic examinations failed to reveal agents known to cause enteric disease, and postmortem investigations failed to indicate the nature of the etiologic agent. A search was made for a nonbacterial pathogen. Since preliminary animal experiments were unsuccessful, human volunteers were utilized. The illness was reproduced and transmitted in series in volunteers, and the responsible agent was shown to be filterable. Oral administration of stool suspensions or throat washings induced the disease, but inhalation of nebulized throat washings did not. Volunteers who were fed material from the third embryonated egg passage likewise remained asymptomatic.

Nephropoiesis Producing Duodenal Symptoms.—Van Duzen presents histories of 3 patients who had been treated for duodenal ulcer and who were relieved by division of fibrous bands running from the hilus of the right kidney to the second

portion of the duodenum. The author believes that these bands represent not an anatomic structure or ligament but a condensation of fibers from Gerota's fascia, which run from the hilus of the kidney to the duodenum. In cases 1 and 2 it was easy to understand how the dropping of the kidney, which was demonstrated by roentgenogram, would produce traction on the duodenum. In case 3 the kidney was fixed in one position and the band constricted the lumen of the duodenum. After section of the band, the duodenum became normal in shape, as proved by later roentgenograms.

Estrogens and Orchiectomy in Prostatic Cancer.—Wattenberg cites investigations which show that repeated injections of estrogens over long periods cause a condition of generalized hyperossification, which fits in with the roentgenologic observations and microscopic sections of skeletal metastases due to cancer of the prostate gland, before and after treatment with diethylstilbestrol and bilateral orchiectomy. The author shows in roentgen ray films and high power and low power views of bone tissue that estrogens can inhibit metastatic carcinoma not only by changing the carcinomatous cells but also by hyperossification about the regressed tumor cells. Views of carcinomatous prostatic tissue before and after treatment with diethylstilbestrol demonstrate that diethylstilbestrol and bilateral orchiectomy can cause a regression of the metastatic carcinoma of the prostate and a regression of the primary carcinoma of the prostate.

Plasmocytoma: Report of Case. J. B. Costen.—p. 671.

Changing Concepts of Sinusitis.—According to Putney surgical treatment of sinusitis has largely been replaced by medical management. The emphasis is on restoration rather than removal or destruction of diseased tissue. The sulfonamide drugs and the antibiotics have changed the treatment of sinusitis. In longstanding suppurative sinusitis the membrane becomes fibrotic and little benefit results from use of the sulfonamide compounds or penicillin. Sinusitis is classified as allergic, mechanical or bacterial. Allergic cases require primary attention to the allergic diathesis; those due to mechanical blockage are relieved by simple surgical procedures, and early bacterial sinusitis responds to penicillin. Penicillin is equally valuable in treating the complications of orbital cellulitis and osteomyelitis of the skull. Surgery can often be avoided when penicillin is given early, but in chronic osteomyelitis surgical drainage is usually needed in addition to the drug.

Trocar Biopsy of Liver.—Volwiler and Jones state that needle or trocar biopsy of the liver has advantages over other methods. When properly performed, it causes little discomfort and, if a fairly uniform pathologic process is present, provides a satisfactory sampling of tissue from deep within the hepatic substance. They have performed 234 needle biopsies with 0.5 per cent mortality. Of the total number, 216 provided sufficient tissue for adequate histologic appraisal; in 79 cases the biopsy was essential to an accurate clinical diagnosis. Aspiration liver biopsy will furnish the following practical information: correct differentiation of extrahepatic and intrahepatic biliary obstruc-

tion when clinical and laboratory data are inconclusive; exact diagnosis of the type of diffuse intrahepatic disease; determination of the particular phase of a known subacute or chronic hepatitis; indications for therapy not obtainable from clinical and laboratory examinations, and accurate evaluation of therapeutic regimens in certain types of chronic hepatic disease. Needle aspiration liver biopsy, has proved a useful and safe measure for making exact diagnoses and for studying the abnormal physiology of disease of the liver.

Renal Damage Following Intravascular Hemolysis.—The observations reported by Burwell and his associates are concerned with the medical management of the anuric patient and with the functional and anatomic reversibility of the renal lesion produced. A housewife aged 29, who had had an abortion during the week prior to admission, recovered from the anuria that followed massive hemorrhage but succumbed three months later to homologous serum hepatitis. During the intervening period the renal function showed steady improvement, as evidenced by clinical and laboratory tests. Necropsy offered a unique opportunity to correlate the residual anatomic lesions with the clinical picture. The fact that the renal function tests improved until the time of death suggests eventual complete recovery. Necropsy showed little residual damage to the kidney.

Treatment of Rheumatoid Arthritis.—Warter and his associates emphasize that the treatment of rheumatoid arthritis should be directed against the etiologic factors rather than the affected joints. Mental and physical rest; maintenance of adequate nutrition, control of pain and eradication of obvious foci of infection are essential to the successful treatment of rheumatoid arthritis. On the premise that foci of infection, streptococci, and their toxins or toxic products play some role in the causation of rheumatoid arthritis, the authors decided to incorporate into their therapeutic regimen the use of streptococcus-staphylococcus-vaccine-toxin toxoid combined antigen. Clinical results with this combined antigen have been as favorable as, and in a number of patients more favorable than those obtained with gold therapy. If the action of gold therapy is to alter the biologic activity of tissue sensitized to infection, then the combined antigen is much safer. The antigen proved effective in arresting and controlling rheumatoid arthritis in 71.1 per cent of the 90 patients observed from two to four years.

Pruritus Ani.—Bacon and Hardwick suggest that pruritus ani may be due to a disturbance in the acid-base balance which resulted in a change occurring in the bacterial flora, this in turn raising the pH of the rectal mucosa. This alkaline reaction has been constantly present in the majority of the cases of pruritus studied by the authors. It is their opinion, based on previous histopathologic determinations, that pruritus ani is a form of chemical dermatitis varying in its skin changes. They have been using since 1946 a medical routine aimed at reducing the pH of the rectal mucosa. This includes an acid-ash diet and glutasin capsules (a form of glutamic acid hydrochloride in combination with pepsin). Gelatin suppositories which contain beta-lactose are used. The diet reduces the pH and the glutasin, which acts as hydrochloric acid when administered orally, aids in this process. The lactose suppositories tend to prevent the seepage of rectal discharges of a high pH during the night. Following evacuations they advise the use of cotton pledgets, using a boric saturated solution to remove secretions. The area is kept thoroughly dry with boric powder. Improvement is evident following the judicious use of this regimen. The authors tabulate observations made on 125 cases of pruritus ani.

Gelatin Nephrosis.—Skinsnes reports on postmortem examinations of 23 patients who received gelatin intravenously in quantities ranging from 100 to 17,600 cc. with widely varying intervals between the final injection and the death of the patient. The gelatin, derived from pig skin, was given in an 8 per cent solution in isotonic sodium chloride solution, usually in doses of 800 cc. The patients died as a result of medical and neoplastic disease or from complications of therapeutic surgical measures. The renal lesion produced by gelatin is compared with that of sucrose nephrosis. Gelatin nephrosis is a reversible change occurring within half an hour after its intravenous administration and disappearing within one hundred and twenty hours following the last injection. Studies of the effect of the renal lesion on renal function are inconclusive. In 1 patient diuresis developed and in another oliguria following intravenous administration of gelatin. Caution is suggested in patients with previous renal impairment. Three cases are reported which suggest gelatin as a potential precipitating factor in coronary occlusion and vascular thrombosis in the presence of circulatory disturbances and vascular disease.

Urinary Hormone Excretion and Testicular Cytology.—Goldzieher and Hamblen report 8 patients selected to illustrate discrepancies between clinical evidence of androgenic activity, urinary hormone excretion and testicular histology. Increased numbers of Leydig cells were associated with low or high 17 ketosteroid excretion, or with normal or high gonadotropin excretion. Decreased numbers of Leydig cells were associated with very low, low, normal or high 17 ketosteroid excretion and with low or high gonadotropin excretion. The authors confirm the observation of Heller and Nelson that there is no quantitative correlation between elevation of gonadotropic excretion and 17 ketosteroid output. Clinical evidence of hypoadrogenism was observed in the presence of low or high 17 ketosteroid excretion. Eunuchoid habitus was present with high, normal or low gonadotropin excretion or with increased or decreased numbers of Leydig cells. A large penis was noted with low, normal or high 17 ketosteroids and a small penis with high normal 17 ketosteroids. Evidence of feminization was

observed with high normal 17 ketosteroids and increased numbers of Leydig cells with low normal 17 ketosteroids and with low 17 ketosteroids and few Leydig cells. Gynecomastia was observed in the presence of increased or greatly decreased numbers of Leydig cells, and yet with normal sized penis. It was seen with normal or low gonadotropin excretion or with normal or low 17 ketosteroid excretion. Hypertrophy or hyperplasia of Leydig cells cannot be regarded as indicative of increased or even of normal secretory activity. It is possible that studies of mitochondria and Golgi apparatus, as well as the use of perfected histochemical technics, may provide adequate cytologic criteria of endocrine cellular activity.

Intestinal Diverticula: Surgical Removal.—Mahorner and Kisner state that duodenal and jejunal diverticula occur in from 1 to 2 per cent of patients who have roentgenographic studies made for gastrointestinal symptoms. The prevailing opinion was that they are relatively innocuous, but they frequently are responsible for disabling symptoms. Medical measures such as a bland diet and recumbency on one side after each meal are acceptable only for patients whose physical condition precludes operative treatment. Surgery is indicated if the symptoms are sufficiently severe. When duodenal diverticula are large enough to cause residual pooling of barium, removal or inversion is indicated. Jejunal diverticula are much less common than diverticula of the duodenum and are much more difficult to diagnose preoperatively. They may cause severe symptoms. Their surgical removal results in cure. The authors describe a new technic of pumping up the duodenum with air to show diverticula which may be hidden, particularly those protruding into the head of the pancreas or into the retro-duodenal area. This new procedure should insure their discovery at the operating table and thus facilitate their removal. A group of 6 cases are reported, in each of which operative intervention was performed and the patient was relieved of his symptoms.

Hyperthyroidism.—According to Crile, thiouracil proved to be an effective means of preparing patients with severe hyperthyroidism for thyroidectomy, but its toxicity was too high to render it acceptable for general use as a definitive treatment. Propylthiouracil is relatively safe, and, although not so effective as thiouracil, it still affords an excellent means of controlling hyperthyroidism without undue danger of side effects. The author used propylthiouracil in 218 patients. The dosage used, 200 to 300 mg. daily, is not always sufficient to maintain a remission. Judging from the prompt recurrences which have taken place in patients who have of their own accord discontinued treatment after a few months of control, incidence of remissions will not be as high as had been anticipated. If the patient is cooperative and can be observed by a physician who is familiar with the structure of the thyroid and the pharmacologic action of the antithyroid drugs, treatment can be extended over long periods. When the patient is uncooperative or cannot be observed periodically, it is preferable to perform a thyroidectomy. Patients with small or moderate sized diffuse goiters with mild or moderate hyperthyroidism, patients with recurrent hyperthyroidism and patients whose life expectancy is short, regardless of the type of goiter, may safely be given a trial on medical management for a year or more. If they respond favorably and prefer medical treatment, this may be continued indefinitely. If they respond poorly or desire surgery, a subtotal thyroidectomy should be performed.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EDEMA OF FEET DURING BUS TRIPS

To the Editor:—A woman patient develops edema of the feet and ankles during prolonged bus trips. The swelling is much less on train rides of two days' duration. She has a slight systolic murmur and a fibroid of the uterus of the size of a baseball, no other pathology. Would you give the reason for this edema?

M.D., Ohio.

ANSWER.—The majority of ambulatory patients with edema of the ankles do not have any cardiac disease. A listing of other causes, most of which concern difficulty in the local circulation in the legs dependent on poor veins, overweight and inactivity, can be found in an article by Foote and associates (The Clinical Significance of Bilateral Edema of the Lower Extremities, *Am. J. M. Sc.* 199:512, 1940). From the data given here it seems unlikely that heart disease is responsible in the case cited. If the heart has not been enlarged and there has been no important dyspnea, the edema is to be ascribed to other cause than cardiac. From the statement that there is "no other pathology" it is unlikely that kidney disease, hypoproteinemia or myxedema plays any role either. There is evidently no other generalized disease process that can be easily identified. To sit or stand for a long time in bus or train would favor edema in a person with faulty leg veins; the longer the trip the greater the amount of such edema.

INJURY TO THE SKIN AND EPITHELIOMA

To the Editor:—A male patient, 35, came into my office May 27, 1947, with a quarter-sized well defined lesion, elevated, infiltrated and erythematous. The center of this area was occupied by a pea-sized verrucous growth. A biopsy of material taken from the edge of the lesion revealed a beginning prickle cell epithelioma, confirmed by a second biopsy. The patient states that on or about April 10, 1947 he was struck by a chip of hot steel while working. He reported to his first-aid station immediately, and a dressing was applied. The area not only failed to heal but continued to increase in size. Several physicians were consulted and several cauterizations were performed, but the lesion continued to increase in size. The question that I would like to pose concerns the time relationship between the trauma and the epithelioma. The patient saw me six weeks after trauma, and the biopsy report of prickle cell epithelioma was present. Can trauma cause an epithelioma in such a short period of time?

M.D., Connecticut.

ANSWER.—Theoretically a causal relation between the trauma and the cancer in this case cannot be excluded. Neither can one exclude a potential or preexisting cancer at the site of the trauma. When one considers the frequency of injuries to the skin in daily life without development of cancer, it becomes difficult to accept a causal relationship. Assuming the existence of a causal relation, the writer is unaware of any clinical evidence to indicate the time necessary for the development of cancer following trauma in man.

ASPHYXIA OF THE NEWBORN

To the Editor:—Please discuss asphyxia of the newborn. Recently I have had the anesthetist give oxygen as the head or breech is being delivered and continue the oxygen until the baby is pink. The cord is not tied until pulsations cease, unless there is evidence of hemorrhage. Is it good practice to administer oxygen to the mother for two minutes before the baby is delivered by cesarean section? If the infant can be delivered without cyanosis, isn't it much better than tying the cord immediately and pumping mucus or other secretions into the lungs while administering oxygen. The secretions are supposed to be removed, but this is not always accomplished. W. R. Moore, M.D., Florence, Ala.

ANSWER.—There is good experimental evidence that the establishment of extrauterine respiration is not the cataclysmic event that it has been pictured. Respiratory movements begin early in pregnancy and continue throughout intrauterine life. They are shallow and occur at irregular intervals but are sufficiently strong to move amniotic fluid in and out of the lungs. Any factor which decreases fetal oxygenation will decrease the frequency of these respiratory movements or stop them altogether for a period of time. Analgesic and anesthetic agents likewise depress intrauterine respiratory activity for varying periods, depending on the drug used. At delivery, oxygenation through the placental circulation stops but the respiratory movements

fill the lungs with air and the extrauterine respiratory pattern develops. Any depression of the intrauterine respiratory movements interferes with the transition to normal vigorous breathing and results in asphyxia.

Asphyxia of the newborn is thus the result of anoxia during the latter part of labor or during delivery. This may be the result of depression of intrauterine respiratory movements by sedative drugs and anesthetic agents or the result of any condition which interferes with placental circulation, such as cord entanglements, partial placental separation, prolonged labor or difficult operative interventions. Increased oxygenation artificially supplied during the latter part of labor and delivery should decrease anoxia, thereby improving the transition from intrauterine to extrauterine respiration.

ALBUMINURIA AND PREGNANCY

To the Editor:—A woman aged 23 was found in a routine examination to have consistently a 2 to 4 plus albuminuria with a few casts and a specific gravity over 1.020 and at times 1.028. The blood count is normal, the blood pressure 100/70. She is asymptomatic. Intravenous pyelograms reveal a good concentration of the dye. Concentration and emptying of the pelvis are equal. The right pelvis is slightly larger than the left. There is a slight ptosis of the right kidney, with a sharp bend in the ureter a third of the distance from the pelvis to the bladder. She had scarlet fever at the age of 5. Several years ago she was kept in bed for "one summer" by a physician, the reason being unknown. She has one child aged 2½ years. During that pregnancy she was "quite sick" during the early months and "felt fine" during the last two months except for swelling of the feet and legs. Labor at term was spontaneous. Her physical condition is satisfactory except for the kidney condition. Should she become pregnant again? If so would there be any reason for early induction of labor or cesarean section to prevent damage to the kidneys? She is anxious to have more children. What is the consensus concerning the induction of labor during the last trimester because of toxemia of pregnancy? Is the induction of labor preferable to cesarean section? What would be the advised method to induce labor in these cases? Is induction of labor or cesarean section preferred in a normal pregnancy with slightly diminished measurements? What statistics afford one procedure the choice above the other?

M.D., Kentucky.

ANSWER.—From the information presented it cannot be established that this patient suffers from actual nephritic damage. An orthostatic albuminuria can well account for the variable proteinuria. Orthostatic albuminuria is particularly suspect because of the demonstrated ptosis of the right kidney and slight hydronephrotic dilatation of the right renal pelvis. Certainly comparison of early morning urine (secreted when the patient is recumbent) with that secreted when the patient is erect and/or active is indicated. In orthostatic albuminuria, urine secreted with the patient recumbent will be free or nearly free of protein; urine secreted during activity, especially walking, may be heavily albuminous. Knowledge as to the quantity of protein lost each day is also desirable in estimating nutritional requirements. If such a test should reveal great variation in protein loss correlated to posture and activity, it might be most worth while to obtain separate specimens of urine from each side by ureteral catheterization after a strenuous walk to determine whether the protein is coming from both kidneys or only from the right.

An orthostatic albuminuria is not a contraindication to additional pregnancies. The patient's vulnerability to hypertension can be determined by application of the cold pressor test, first described by Hines and Brown and applied to analysis of the renal vascular problems of obstetrics by Dieckmann and Michel (Dieckmann, W. J., and Michel, H. L.: *Arch. Int. Med.* 55:420 [March] 1935. Hines, E. A., Jr., and Brown, G. E.: *Proc. Staff Meet., Mayo Clin.* 7:332 [June 8] 1932; Hines, E. A., Jr.: *Am. Heart J.* 19:408 [April] 1940).

It is impossible to predict the desirability of early induction of labor in future pregnancies. Frequent antepartum observation should be an adequate guide. The appearance of hypertension during pregnancy is a more significant warning than albuminuria; preexistent nephritis exacerbated by pregnancy is a progressive disorder with a relatively poor prognosis and considerably increased fetal mortality if permitted to continue to full term. Abruptio placentae is a common complication. Hypertension is the most useful criterion of hazardous intoxication. Anemia is also of the greatest importance; future antepartum care should include frequent observations of the blood count and liberal nutritional supplementation to keep the hemoglobin content near optimal levels.

The choice between induction of labor and cesarean section depends largely on factors not stated in the query: pelvic measurements, ease of delivery of the first child and the like. In most instances of nephritis and/or hypertension complicating late pregnancy, conservative medical induction with castor oil and quinine and/or rupture of the bag of waters usually suffice. Cesarean section is indicated in primiparous patients who fail

to respond to conservative measures and who have a long, hard and undilated cervix, a viable baby and intact membranes. Pituitary injection, if administered at all, must be given cautiously because of the hazard of inducing a sharp rise in arterial tension. When any cephalopelvic disproportion exists, the administration of pituitary injection before delivery of the infant is contraindicated. For further discussion of the purely obstetric aspects of the problem, any of the standard textbooks on obstetrics should be consulted.

EFFECT OF "BENADRYL" ON PREGNANCY

To the Editor:—Is there any contraindication to the use of "pyribenzamine hydrochloride" (tripelennamine hydrochloride) or "benadryl hydrochloride" (diphenhydramine hydrochloride) during pregnancy? I have a patient who is severely affected during the ragweed season. During her pregnancy last summer she took both "benadryl" and "pyribenzamine" regularly. In the seventeenth week of her pregnancy she aborted, passing the placenta but no grossly recognizable fetus. Her uterus at the time was enlarged only to half its expected size at that period. She is pregnant again and is beginning to have severe vasomotor rhinitis and asthmatic attacks. Can she take either "benadryl" or "pyribenzamine" for the relief of these symptoms without endangering her pregnancy? I would appreciate an early reply, due to the urgency of the case.

M.D., New York.

ANSWER.—Both of these drugs have been used extensively during the past year and thus far reports do not indicate that they may produce abortion. In a patient who may have drug sensitization, drug sickness may ensue which, it could be assumed, might of itself have some undesirable effect in pregnancy. This is true of any illness during the antepartum period. In the present instance it is probable that the patient is not in this category, since it was administered during the previous pregnancy.

POSSIBLE CONGENITAL DIVERTICULUM OF THE BLADDER

To the Editor:—I have under my care a boy 3½ years of age, who passed bloody urine on one occasion about two years ago, but since has had no further urinary symptoms. A presumably congenital diverticulum of the bladder was demonstrated by urogram. He now complains occasionally of mild pain below the navel. Since no other explanation can be found, it is thought that the pain might be caused by the diverticulum. Do you feel that, in the absence of symptoms, surgery is advisable? At what age should this surgery be undertaken, if at all?

M.D., California.

ANSWER.—One may not presume that a diverticulum of the bladder is congenital. Cystoscopic observation is imperative in the given case. An obstructive lesion at the bladder neck may have caused the diverticulum and may now be causing irreparable pathologic change of the upper part of the urinary tract in addition to the pain below the navel. Among the obstructive lesions in a child aged 3½ years one may mention: contracture of the vesical neck; bands, folds or valves of the posterior urethra; hypertrophy of the verumontanum; meatal stricture; preputial stricture, and anterior urethral stricture.

To complete the examination retrograde pyelograms should be made and differential renal function should be ascertained to establish the integrity of the upper part of the urinary tract.

If an obstructing lesion is found it should be corrected regardless of age. Subsequently, the diverticulum may not need surgical correction.

THE SEDIMENTATION RATE DURING PREGNANCY

To the Editor:—Is blood drawn from the vein as accurate for use in taking a blood count as the usual prick of the finger? How much does the normal sedimentation rate rise during pregnancy, and when must pregnancy be taken into consideration when evaluating the moderately rapid sedimentation rate due to other causes such as rheumatic fever?

M.D., New Jersey.

ANSWER.—Blood drawn from the vein and introduced into a proper anticoagulant is an accurate and reliable source for the determination of the red count, white count, hematocrit, platelet count and certain other observations. It is more reliable than samples obtained by capillary puncture. The anticoagulant of choice is dry oxalate mixture, which is made as follows: Three grams of crystalline ammonium oxalate and 2 Gm. of crystalline potassium oxalate are dissolved in distilled water with the aid of heat and made to a final volume of 100 cc. This gives a final concentration of 5 Gm. per hundred cubic centimeters of mixed oxalates. The concentration used in blood is 200 mg. of oxalate mixture per hundred cubic centimeters of whole blood. The standard amount of blood taken for hematologic observations is 5 cc. For convenience, the following procedure is used:

A stock of bottles or tubes is prepared in advance to receive 5 cc. samples of blood by pipetting into each receptacle 0.2 cc. of the solution of oxalate mixture and drying the anticoagulant in the room, in a desiccator or in an oven, using a temperature of less than 180 C. When dry, stoppers are added. Receptacles containing dry oxalate mixture can be stored indefinitely without deterioration.

WARNING: Dry oxalate mixture cannot be used for any chemical test in which nitrogen determinations are made, since it contains ammonia.

The sedimentation rate of red blood cells increases during the last trimester of pregnancy in a gradual and progressive manner, reaching a maximum immediately after delivery. It then decreases to normal, but this may require a period of several weeks. This is related to an increase in the concentration of plasma fibrinogen during the latter portion of pregnancy and the puerperium. Therefore, a moderate elevation of sedimentation rate occurring during the last half of pregnancy must be considered as possibly related to the pregnancy itself. For both the question concerning the anticoagulant and that concerning the sedimentation rate, reference is made to Wintrobe, M. M.: Clinical Hematology, edition 2, Philadelphia, Lea & Febiger, 1946.

DAMAGE TO SIGHT AND HEARING FROM ELECTRIC SHOCK

To the Editor:—A man aged 23 came in with unilateral deafness and poor vision (20/200) in the eye on the same side as the deafness. His history was "being struck by a wire carrying 275 volts direct current over that ear alongside the head." Two men had been killed previously by the same type of accident. Examination revealed total deafness in the left ear but no perforation of the tympanic membrane. Eye examination revealed no fundus lesion and vision could not be improved. The patient's past history was that he has been discharged from the navy with normal vision. This accident put him in the hospital for nine days. Could an electric shock such as this cause an injury to produce deafness and blindness? M.D., West Virginia.

ANSWER.—An electric shock of 275 volts, with sufficient amperage, could cause such a condition. The fact that two men had been killed by such a shock is evidence that the amperage was high. Damage is often on both sides with diffusion of the electric shock, but a local shock, leaving no severe skin burn, can cause severe damage to deeper structures. If the caloric labyrinth tests produce no nystagmus there is presumptive evidence of eighth nerve damage. Severe optic nerve damage can occur from electric shock. Such cases later show the picture of optic atrophy.

SUBACUTE NEPHRITIS

To the Editor:—A man, 29, in good general physical condition, has had subacute nephritis for the last six months. The onset presumably followed a streptococcal tonsillitis. Some improvement followed the usual dietary measures and a course of penicillin, 150,000 units, over a period of seven days. He still has albumin (3 plus), with red and white blood cells and some renal epithelia in his urine. His blood pressure has varied within fairly normal limits, and there has been transient moderate increase in nitrogen urea, uric acid and creatinin. Eye grounds have been essentially normal. The tonsillar stumps are buried and there is moderate adenopathy in cervical lymph nodes. Although several cultures have been made from specimens of catheterized urine on only one occasion has a streptococcus been recovered. The question of complete surgical removal of the tonsillar stumps arises, and I would appreciate an opinion as to its advisability. Would the risk of causing the renal disease to flare up be diminished by a preoperative course of penicillin?

Rudolph V. Gorsch, M.D., New York.

ANSWER.—The advisability of immediate complete removal of the infected tonsillar stumps cannot be dogmatically affirmed or denied. Certainly it would be desirable to remove these foci of infection which may be constantly reinfecting the kidneys, but there is hazard in the probability of a bacteremia induced by trauma to the infected throat. It would appear more desirable to attempt first more intense antibiotic therapy with penicillin, 40,000 units every three hours for five or six days. After this, urinary, throat and blood cultures as well as estimation of the renal functional capacity should be carried out. If tonsillectomy is to be performed at a later date, both preoperative and postoperative administration of penicillin is desirable.

Unfortunately, no mention is made of any examination of the blood, either by culture or routine hematologic methods. Anemia is an almost universal consequence of acute nephritis, and its continuance plays an important role in the perpetuation of the disorder. Injured structures can hardly be expected to repair themselves effectively unless they are obtaining a nearly optimum blood supply. If anemia coexists, as it most probably does, it should be energetically combated, even to the administration of whole blood by transfusion.

IN VIVO AND IN VITRO STREPTOMYCIN RESISTANCE OF TUBERCLE BACILLI

To the Editor:—In many institutions where streptomycin is used for tuberculosis the value of continued treatment is judged by culture resistance of the involved organism. Has any work been done which indicated that resistance in vivo is definitely a corollary of any resistance which may be found in vitro? Lester Leonard, M.D., Miami Beach, Fla.

ANSWER.—The exact relation between the in vivo and in vitro resistance of tubercle bacilli to streptomycin in man is not apparent as yet. However, the resistance developed to streptomycin by tubercle bacilli from 8 of 12 patients ranged from five hundred to a thousand times as great as that of cultures taken before treatment (Youmans and associates). This resistance is retained even after residence in guinea pigs for ten weeks or more and may subsequently be maintained on glycerinated egg yolk agar for many weeks (Karlson, Feldman and Hinshaw). Even in vitro there is a wide variation in the rate of resistance development, ranging from twofold to a thousandfold (Williston and Youmans). It was noted recently that "the clinical significance of the resistance to streptomycin developed by tubercle bacilli is not definitely established" (Youmans and Karlson) after a study of 131 strains prior to treatment (90 per cent being inhibited in concentrations of less than 2 micrograms per cubic centimeter medium); a small number of strains were isolated and tested following treatment with streptomycin, some attaining a resistance of about 2,000 micrograms. In white mice streptomycin-resistant human tubercle bacilli were found to be as virulent as streptomycin-sensitive strains, and infection with these streptomycin-resistant cultures was not suppressed by treatment of the mice with streptomycin (Youmans and Williston).

SMALL FEMALE BREASTS

To the Editor:—A woman, aged 22, who has been previously married and has a child 3 years of age, complains of very small breasts. Physical examination presents no abnormalities other than the one of which she complains. The mammary glands are hardly larger than those of a male. The patient is so concerned about this condition that it is becoming an obsession with her and she is developing a neurotic condition. I have hesitated to use hormonal treatment because it was felt that no definite results could be promised. Will you please outline any possible hormonal treatment that may be of value in this case.

M.D., Alabama.

ANSWER.—It can be stated rather definitely that hormonal therapy, that is, estrogens, will induce growth of the breast only in those patients who have an estrogen deficiency—for example, those with infantile sexual organs or those in the climacteric. The administration of estrogens to a normally menstruating woman seldom gives rise to growth of the breast, although it is possible that massive doses may induce some engorgement of the breast similar to that seen in chronic cystic mastitis. Nevertheless, in those patients in whom the breasts respond to the administration of estrogens there is a recession in size following the cessation of therapy.

TREATMENT OF MERCURY POISONING

To the Editor:—A child 3 years of age ate 2 teaspoonfuls of ointment of ammoniated mercury. What is the treatment? M.D., Massachusetts.

ANSWER.—Two teaspoonfuls of either the 5 or 10 per cent ammoniated mercury ointment contains sufficient mercury to prove fatal to an adult. Ammoniated mercury is about equal in toxicity to bichloride of mercury and in fact, due to the method of manufacture, may contain appreciable quantities of the latter. As variously formulated, this ointment may have as its base only petrolatum, an indigestible but emulsifiable fat, or instead, petrolatum along with hydrous wool fat, a digestible fat. In either case an undetermined portion of the mercury may leave the alvine tract unabsorbed. Notwithstanding, prompt emesis and repeated gastric lavage are indicated. Promptly also

BAL (2,3-dimercaptopropanol) injections should be given. The dose most recommended is 1.2 cc. of the 10 per cent solution per 100 pounds (45.4 Kg.) of weight, introduced intramuscularly four times daily for two days and diminished thereafter. Thus the dose for a 30 pound (13.6 Kg.) child would approximate 0.4 cc. Best results are to be expected if treatment is begun within three or four hours. Delayed treatment with BAL still may be of some value. The total experience in the BAL therapy of mercury poisoning, particularly in children, is so limited that categorical statements may not be made. Any further treatment should be on a symptomatic basis.

STREPTOMYCIN AND RENAL TUBERCULOSIS

To the Editor:—Kindly advise me about the use of streptomycin in renal tuberculosis. What dosage is advisable and how long should treatment last? A. A. Skemp, M.D., LaCrosse, Wis.

ANSWER.—Streptomycin has been used to a limited extent in the treatment of renal tuberculosis. In the report of Feldman (*J. Roy. Inst. Pub. Health & Hygiene* 9:267, 297, and 343, 1946) from data supplied by Hinshaw up to May 1946, 14 patients had been treated with apparently favorable response in 8. The improvement consisted in a decrease in pyuria and in the number of bacilli excreted; in cases in which the bladder was involved the urinary frequency was decreased and the capacity of the bladder increased. In 6 of the improved patients the process was not arrested, whereas in 2 it was possibly arrested. The dosage of streptomycin for treatment in these cases is 1.5 to 2 Gm. a day for eight to twelve weeks.

TREATMENT OF CONDYLOMATA ACUMINATA WITH PODOPHYLLIN

To the Editor:—In some recent publication, which I have misplaced, there was an article relative to condyloma acuminatum and its treatment with podophyllin suspended in liquid paraffin. Please comment on the effectiveness of this treatment and inform me of the proportion and preparation of the proposed treatment.

C. P. McKenzie, M.D., Mexia, Texas.

ANSWER.—In a paper entitled "A Study of the Effects of Podophyllin on Normal Skin, Condylomata Acuminata and Verrucae Vulgaris" (*Arch. Dermat. & Syph.* 56:30 [July] 1947), Sullivan and King described the various methods of treatment with podophyllin. There is also discussion of modifications of treatment by various dermatologists at the end of this article. The use of podophyllin was probably first introduced by Kaplan in 1942 (Culp, O. S. and Kaplan, I. W.: *Condylomata Acuminata. Two Hundred Cases Treated with Podophyllin. Ann. Surg.* 120:251 [Aug.] 1944). In regard to the cytologic effects of podophyllin (Sullivan, B. J. and Wechsler, H. I.: *The Cytological Effects of Podophyllin. Science* 106:433 [April 25] 1947), reports by numerous authors on the use of this drug in various vehicles in the treatment of condyloma acuminatum have, on the whole, been most favorable. Careful attention must be given to the various technics of application in order to avoid untoward results.

TESTOSTERONE IN TREATMENT OF SCHIZOPHRENIA

To the Editor:—Has testosterone propionate been used in the treatment of schizophrenia? If so, I would like a bibliography.

Bryce P. Weldy, M.D., Hartford City, Ind.

ANSWER.—Testosterone propionate has been tried in the treatment of schizophrenia but not extensively. There has not been much indication to use it except in those cases in which there was hypogonadism. A single report by Sutherland and Hoskins was good, but the follow-up has been only for two months. Guiridham reported 4 cases, in 2 of which patients with schizoid elements showed pronounced improvement after treatment with testosterone; on another occasion he reported 3 cases, 1 that of a catatonic schizophrenic person, who responded well. It is probable that the cases in which such treatment is indicated are exceedingly few. The bibliography is as follows:

- Guiridham, A.: Function of Testosterone in Mental Disease. *Bristol Med. Chir. J.* no. 220, 59:1-6, 1942.
Guiridham, A.: Treatment of Mental Disorders with Male Sex Hormones. *Brit. M. J.* 1:10-12 (Jan. 6) 1940.

DYSpareunia: A PROBLEM FOR THE GENERAL PRACTITIONER

ROBERT T. FRANK, M.D.
New York

Dyspareunia, which signifies painful or difficult intercourse, is a not infrequent disturbance. It has wrought havoc in many marriages and, even if of minor degree, has caused unhappiness and discomfort. Eventually it may produce serious neuropsychiatric symptoms.

Most frequently the family physician is the first to be consulted, particularly by newlyweds whom he has known since childhood or adolescence. Too often the general practitioner, because he has not been instructed in medical school, proves ill qualified to be a useful counselor. Moreover, he will find little useful guidance in the textbooks.¹ To meet this gap, I have reviewed the histories of a considerable unselected series of cases of dyspareunia from my private records, in order to present and clarify the subject and offer guidance in this little discussed field.

The entire series comprised 349 patients representing 1.5 per cent of the patients encountered in office practice over a period of years.² Of the 349 patients, 105 (29.6 per cent) complained solely of dyspareunia, 165 (47.7 per cent) gave it as the main complaint and 79 (22.7 per cent) mentioned it incidentally, usually at a later visit, after their trust and confidence had developed to a greater degree.

In 113 patients, in addition to dyspareunia, other complaints were elicited (table 1).

Of the entire group of 349, 156 patients had become pregnant (44.6 per cent); 128 had borne one or more children, the remaining 28 having abortions only (1 had twelve). One hundred and ninety-three, or 55.3 per cent, had never conceived, but only 39 complained of sterility.

In 114 patients the trouble had existed since marriage (table 2). This included 37 in their honeymoon (arbitrarily limited to the first month or two of marriage).

1. The literature is widely scattered. Most informative, especially in regard to local lesions, is Dickinson, R. L., in Nelson's Loose Leaf Surgery, New York, Thos. Nelson & Sons, 1932, vol. 7, chap. 32, p. 681. Other references are: Bell, W. B.: Disorder of Function, in Eden, T. W., and Lockyer, C.: The New System of Gynaecology, London, Macmillan & Company, 1917, vol. 1, p. 397; Crossen, H. S., and Crossen, R. J.: Diseases of Women, ed. 9, St. Louis, C. V. Mosby Company, 1941, p. 806; Curtis, A. H.: A Textbook of Gynecology, ed. 4, Philadelphia, W. B. Saunders Company, 1942, p. 619; Novak, E.: Textbook of Gynecology, ed. 2, Baltimore, Williams & Wilkins Company, 1944, p. 509.

2. To arrive at a percentage, a sample of 7,124 consecutive histories were scrutinized; 103 cases of dyspareunia were found, or 1.4 per cent.

As a generalization it may be stated that other factors being alike, the gravity of dyspareunia is proportional to the length of its duration.

Patients localized their pain as introital, deep or both. In 5 patients the site was not obtained (table 3).

LOCAL CAUSES

Primary Dyspareunia.—Primary dyspareunia, of which honeymoon dyspareunia is the most striking example, begins with the first attempts at intercourse (113 cases, 32.7 per cent). Of these, 37 were honeymoon cases, the remainder having persisted from one to twenty years.

The dyspareunia, as mentioned, may be introital or deep. Honeymoon symptoms usually are introital, resulting from hymeneal tears, lacerations of the fourchette or bruises of the urethral meatus.³ A thick, rigid hymen may prove an insurmountable or painful obstacle.⁴ Subsequent to the injury superficial ulcerations develop which prove exquisitely painful to the touch.

The treatment of such lesions usually is simple. Twin beds, interdiction of intercourse, hot sitz baths and, if the vulva is painful and swollen, wet dressing of 0.5 per cent aluminum acetate. Occasionally codeine and sedation may be required. If pronounced spasm, vaginismus or anxiety has already appeared, after healing is complete, a matter of ten to fourteen days, the tube treatment (discussed later in this article) should be resorted to for two weeks before intercourse is resumed.

Forty-three patients showed introital lesions due to inflammatory causes—skeneitis (inflammation of periurethral glands), bartholinian abscess or cyst, inflammation of labial sweat glands, nonspecific leukorrheal irritation (including *Trichomonas* infestation). The treatment of these lesions was along orthodox lines. Bartholinian cysts or abscesses were excised; superficial labial inflammations kept clean and dry; leukorrhea relieved by cervical and vaginal applications of silver nitrate and merbromin ("mercurochrome"), 2 per cent, and douches. No case of gonorrhea was encountered.

3. More serious injuries may confront the physician for treatment. Over an interval of years I have been called late at night on three occasions to stop serious hemorrhages due to wedding night hymeneal lacerations. In 2, packing sufficed; 1 required hemostatic suture. Twice large perivaginal hematomas were encountered. These subsided spontaneously. In 1 patient coitus (which had been indulged in without difficulty with the same partner for months) caused profound shock due to perforation of the posterior fornix; cure was effected with short iodoform pack in Douglas cul-de-sac and morphine.

4. In the entire series, intact hymen was encountered twenty-five times. Eleven of these patients were honeymooners. In 5, tubes cured; in 3, hymenectomy was performed. The treatment of 3 was not in my care. The duration was thirteen years in case 2, and ten years in a 46 year woman (husband impotent—no therapy attempted!). The remainder were married from one to six years.

Seven cases of congenital septums required surgical excision. Absence of vagina is a bar to coitus and will not be considered here.⁵

Secondary Dyspareunia.—Introital: Secondary introital changes caused dyspareunia in 70 patients (20 per cent). This signifies that the trouble developed after the honeymoon, in some cases many years later.

TABLE 1.—Additional Complaints

Dysmenorrhea	32
Sterility	39
Menorrhagia and metrorrhagia.....	26 (fibroids 15)
Amenorrhea	8
Cystoectocoele	8*

* Of the 8, only 1 had uterine prolapse. She was cured by a Manchester operation. Two with rectocystocele evinced strong defense reactions. Five had rectocystocele (duration, one to thirty-two years), experiencing introital (4) or deep (1) dyspareunia.

TABLE 2.—Duration of Dyspareunia

Duration of less than 1 year.....	107
1-2 years	84
2-5 years	52
5-10 years	38
10 or over	20
Not accurately ascertainable.....	48

Menopausal involution, dryness and thinning of the mucosa were at fault in 23 cases. Acute onset may follow roentgen sterilization. In mild cases, lubrication proved sufficient to relieve. When pronounced senile changes were noted, occasional twelve day courses of estrogenic vaginal pessaries of 2,000 international units proved helpful. The condition is particularly disturbing when the women are young (artificial menopause) or in older women married to younger husbands.

Too tight perineorrhaphies following plastic repair produced dyspareunia in 33 women, in the majority at once after the operation; in a few, years later when the superadded menopausal shrinkage further diminished the lumen. In 13 women, overtightness of episiotomy repair caused the trouble post partum. In 1 patient, kraurosis was at fault.

TABLE 3.—Site of Dyspareunia

	No.	Percentage
Introital	207	60
Deep	100	29
Both	37	10
Not ascertained	5	1

TABLE 4.—Causation of Primary Introital Dyspareunia

Honeymoon lesion	37
Rigid hymen	33
Vulvovaginal inflammation	24
Leukorrheal irritation	19

In some instances, lubrication and more dorsal intro-mission relieved the pain. In a number, a reverse plastic operation was required (vertical incision through the fourchette and into the perineum with transverse repair of the resulting gap). In some, tube treatment brought relief. In kraurosis, vulvectomy was performed, primarily for the precancerous lesion, simultaneously curing the dyspareunia.

Deep Dyspareunia.—Deep dyspareunia is noted particularly in retroflexion with prolapsed ovaries, in the presence of pelvic inflammation and after postabortal infections.

I never have operated on retroflexion for dyspareunia per se (33 cases). Twice daily knee-chest position (for five minutes, with admission of air by separating the labia or introduction of disconnected douche tip) is prescribed; later, when the uterus is more movable, insertion of an appropriate Hodge or Smith pessary assures antelexion. Two patients operated on by others returned unrelieved, their trouble being largely psychogenic in origin.

Dyspareunia due to pelvic inflammation (47 cases) required treatment of the underlying lesion. Exudates are relieved by rest, heat, diathermia (2 cases due to gold intracervical contraceptive button); adequate penicillin therapy (1,000,000 units in three and one-half days). Rarely hydrosalpinges or pyosalpinges required operation. In a few chronic conditions of secondary contracture of the pelvic connective tissues, the vagina was stretched by mercury colpeuryesis.

In 7 patients deep dyspareunia was cured by forbidding the use of the contraceptive diaphragm. These women all submitted to intercourse at least once daily. The site of pain was in the tense, spastic sacrouterine ligaments, traumatized by the frequent prolonged pressure exerted by the diaphragm.⁶

TABLE 5.—Causation of Secondary Introital Dyspareunia

Menopausal involution	23
After perineorrhaphy	33
After episiotomy	13
Kraurosis vulvae	1

In 10 instances of endometriosis, the first complaint was that of deep dyspareunia. The treatment is that of the endometriosis which, if widespread or accompanied by chocolate cysts, required radical operation.

Combined Dyspareunia.—In 37 patients, both introital and deep dyspareunia was complained of. They fell into various categories, inflammation predominating. A number showed a hypersensitive pelvis (accompanied by general hyperesthesia) most often resulting from incomplete deturgescence due to coitus interruptus.

NORMAL PELVIC FINDINGS

In 63 patients (17.5 per cent), the pelvic findings were approximately normal. These patients were the most difficult to classify and cure. Of these patients who were found locally normal, neuroses and psychoneuroses were evident in 54.8 per cent, contrasting with those patients in whom recognizable pelvic lesions were found and who showed only half as many nervous symptoms (24.6 per cent).

Consequently in classification and in treatment there is a sharp distinction in patients with dyspareunia between those with local pelvic lesions calling for local treatment and those in whom neuroses, psychoneuroses and general psychosomatic symptoms predominate. These may require psychotherapy. That my material does not differ greatly from that of other gynecologists is shown by Dickinson's observations,¹ who, in 170 patients with dyspareunia, found that the psychic factor

6. One woman not included in this series experienced violent pain in the vulva and vagina with acute dermatitis. Careful investigation uncovered a suddenly developed allergy to rubber (a rubber condom was used).

predominated in 25 per cent. In mine, the percentage was 24.6 per cent of 349 patients, an almost identical figure.

PSYCHOGENIC DYSPAREUNIA

The recognition of dyspareunia resulting from neurogenic causes is nothing new. Huguier⁷ in 1834 wrote his thesis on vaginismus. Dupuytren⁸ in 1839 recognized dyspareunia. Faure,⁹ 1928, deplored the fact that prophylactic measures are rarely feasible and emphasized the effect of lack of love or actual distaste in "arranged marriages," which were the rule in France.

Whether increasing frequency of premarital consultation, enlightenment on the subject of sex or prenuptial self dilatation, as advised by Dickinson,¹ will eventually reduce dyspareunia to a rarity still remains to be seen.

My own education in the evaluation of dyspareunia and in its effective treatment began more than thirty years ago. The literature afforded me little aid. My training largely was autodidactic. It has progressed with the general development of psychology, both normal and abnormal, and psychiatry. A few of these early cases may prove as enlightening to the reader as they were to me.

CASE 1.—The patient, seen June 2, 1915, was 23 years old, had been married one year and experienced dyspareunia without real intromission. Her husband was young, timid and inexperienced. I inserted a large vaginal plug with the patient under anesthesia. She was unable or unwilling to insert the

plug subsequently because of pain and vaginismus. On July 13 I excised the hymen and enlarged the introitus by a vertical cut in the perineum, which was stretched and sutured transversely. The dyspareunia improved. The patient became pregnant nine months later. She has not experienced dyspareunia since term delivery.

This case shows that the highly recommended forcible dilatation and even enlargement of the entrance did not at once establish a complete cure. A further milestone in my education was supplied by the next case.

CASE 2.—The patient, a nullipara aged 36, married thirteen years, was referred to me in August 1915 by an internationally prominent internist with the "royal command" to perform an excision of the hymen. The patient was intelligent and nervous and did not want children. Dyspareunia had existed since marriage. The patient was underweight, fully feminine and normal. The hymen was found intact after thirteen years, admitting only the tip of the finger; there was vaginismic general spasm.

Reluctantly, because of the long duration and nervous background, with the patient under general anesthesia I excised the hymen. Three days after the operation, while still in the hospital, the patient tried to jump out of the fifth story window. Within two months she had to be committed to an institution for the now overt psychosis with suicidal tendencies.

I have never forgotten this lesson. It has led me to study the nervous makeup of every patient that I have since encountered as an integral part of every anam-

nesis and examination. These early cases laid the foundation for further study and interest in dyspareunia and (the then as yet not coined term of) psychosomatic symptoms.

When dyspareunia, with or without complicating vaginismus, is based on nonlocal causes or when local complaints are far overshadowed by nervous symp-

toms, it indicates a defense mechanism developed by the patient. The defense may be directed against sex and physical congress in general (faulty upbringing, excessive egotism, old maidishness, latent or overt homosexuality), fear of pregnancy, aversion to partner (previous love affair, broken engagement, some physical defect discovered after marriage). Even minor annoyances such as lack of consideration in preliminaries, unpleasant conditions like halitosis or bromhidrosis, may form the basis of aversion and subconsciously the beginning of resistance and defense.

According to the usual criteria, 63 patients showed pronounced neuroses existing, as well as I could determine, from one month to fourteen years, with an average of two years. Twenty-three patients suffered from more serious psychoneuroses. Of these, the further course in 3 ended in true psychoses. The duration was from four months to fourteen years, with an average of five years.

The causal factors were difficult to elicit, particularly in cases of long duration, then being overshadowed by the anxieties, fears, grievances and the often irrelevant and multiple psychomatic symptoms which dominated

the picture at the time of examination. Dissatisfaction or anger against the husband, in some cases fully justified, was elicited in a number of instances (vide infra).

A breakdown of the data relating to causation is instructive (tables 7 and 8).

In the patients with neuroses, 58.7 per cent, and in those with psychoneuroses, 78.3 per cent showed no local lesion to account for the fixation of their trouble. It became necessary to explore more deeply into the origin and cause. That this causation was not too easily recognizable is demonstrated by the fact that at least 4 had been subjected to multiple operations directed to

correct functional psychosomatic symptoms, with no relief but rather with increase of disability. Yet these same patients were ready and eager to submit to further operative intervention!

Considerable exploration was needed to arrive at even the scant data contained in the preceding tables (tables 7 and 8). These patients have this in common, that they focus their complaint on the pain, discomfort, aversion, fear, fatigue or humiliation which they experience before, during or after coitus. Some develop a physical defense reaction (vaginismus, 7 cases) which may extend to the abdominal and extremity muscles, and others use evasion or excuses of ill health to avoid coitus. A number of these patients had undergone or were undergoing formal psychoanalysis.

THE HUSBAND

Before discussing treatment of these patients, a consideration of the husband is indicated. My data are restricted by the fact that I had no direct contact with the male partner in many instances, and therefore was limited in my search for the truth by the often prejudiced statements of unhappy and disgruntled wives.

The data in table 9 on 36 husbands are available and appear well founded.

Less classifiable complaints such as brutality, inconsiderateness, drunkenness and unwillingness to take contraceptive precautions were not uncommon. In a number of instances, a genitourinary specialist to whom these husbands were referred was able to help them.

TREATMENT

During the course of years, I have developed a simple technic which has rarely failed in patients who wanted to be cured! The attitude of the patient, therefore, must be explored carefully and minutely at the outset. This inquiry can be accomplished in a surprisingly short time if one's manner and approach are genuine, unembarrassed, quite impersonal but kindly. The feeling toward the husband, the presence or absence of libido, the hopes and fears and anticipations—whether reality has fulfilled or fallen short—can be obtained rather readily from the average patient. The site, character and intensity of the pain, the time of its occurrence and whether trial has shown progressive decrease or increase of its intensity help to complete the picture. If because of timidity, prudery or fright—in contrast to deliberate noncooperation or purposeful concealment or lying, which signify deeper psychic disturbances demanding trained psychiatric approach—the situation remains unclear, then the first examination must be limited to painless maneuvers, if necessary, omitting vaginal examination completely. Coitus is forbidden, and hot sitz baths, sedation and twin beds are ordered.

At the next visit (five to seven days later) the improvement in "entente" will be great. A short separate interview with the husband, who has been invited

but too often fails to attend, will enlighten him and enlist his full cooperation unless he is stupid or purposely uncooperative, the latter usually signifying some defect such as impotence, which he desires to conceal.

Local examination (one finger vaginal, small speculum) shows entire absence of local lesions and local causes, but may arouse spasm (local or general), even though no pain is elicited by the deliberate and calculated gentleness of the examination.

Treatment with Tube.—With the patient still in the lithotomy position, I then produce with emphasis and almost ostentation, two pyrex test tubes, one $\frac{5}{8}$ inch (0.96 cm.), the other 1 inch (2.54 cm.) in diameter, instruct the patient for the first week to insert the smaller tube, well lubricated, twice daily for ten minutes by the clock. The patient's position should be dorsal, with thighs drawn up and separated, the introduction deep, and this maneuver should be repeated at least three times at each session. The patient then herself introduces the tube under my supervision, and if necessary, is repeatedly instructed and encouraged further. The larger-sized tube is used during the second, and in difficult patients, also during a third week. The patient is assured convincingly that at the end of this period coitus will not only cause no pain but may prove pleasurable.

The result has been almost 100 per cent cures in one or at most two office visits except in the few in whom a deep-seated psychic basis exists.

Several of the patients have informed me that they were undergoing or shortly before had completed a course of psychoanalysis. Under these conditions I have insisted on first obtaining the consent of the analyst, which has been accorded in every instance. The result in those patients particularly has been good as far as overcoming local pain and spasm is concerned, as well as some of their apprehension.

In spite of the multiple factors which form the background of dyspareunia—local lesions, the upbringing, personality, nervous constitution, health and compatibility of both partners—few conditions encountered by the physician respond more readily to adequate recognition and treatment. Certainly no more grateful patients than those cured of this source of pain and unhappiness can be found.

To recapitulate, the treatment of dyspareunia based on local lesions is direct and simple, as has already been shown. Not infrequently emotional, social and psychic factors will crop up as side issues. If the patient is open minded, cooperative and desires to be cured, enlightenment is not difficult. If possible, a free discussion between husband and wife, in the presence of and with the physician as guide and moderator, is most helpful. It may then become evident that the husband is partly or entirely at fault and that he is the one who needs local or psychiatric treatment.

A more cautious approach is necessary in those patients in whom the local findings are normal or minimal and the duration of the trouble of long standing, and who, in spite of the fact that they seek advice, evince a balky resistance to investigation. The predominantly defensive nature of their reaction, even if it is camouflaged by unrelated psychosomatic symptoms, anxieties, excuses and accusations against their husbands, is readily recognizable. In the worst cases of this type, unless the patients have been referred to me by a psychiatrist or psychoanalyst who requests that

I try to ameliorate the local symptoms, I try to determine whether the patient wants to be cured. Some have rationalized the situation, have arrived at a status quo which satisfies them, particularly if the husband is acquiescing, indifferent or has found solace elsewhere. Such patients should not be treated; otherwise you run the risk of catastrophe as in case 2. If the patient wants to be cured, then the tube treatment is successful in the vast majority of cases as far as relieving local pain, spasm and resistance is concerned. It will not cure phobias, it will not make a disliked husband attractive, but it will make coition physically painless and, when no deep-rooted prejudices exist, responsiveness may develop.

SUMMARY

Dyspareunia in a series of 349 patients represented an incidence of about 1.5 per cent of gynecologic private patients seen during the same period. In approximately 30 per cent, dyspareunia was the sole complaint; in 48 per cent it was the major complaint, and in 22 per cent it was an incidental complaint. In 30 per cent the dyspareunia has existed since marriage. In the entire series the duration varied from honeymoon (one to sixty days) to ten years or more. The site of pain was introital in 207 (60 per cent), deep in 100 (29 per cent); both superficial and deep in 37 (10 per cent), and not ascertained in 5.

Localizable symptoms required local treatment in addition to psychic suggestion. Nonlocalizable and "psychogenic" cases required different therapy.

Symptoms which developed with marriage were termed primary; they were termed secondary when onset occurred later.

Primary introital dyspareunia most commonly developed as a consequence of coital trauma, local infection and leukorrheal irritation (including *Trichomonas*). In 7 cases, congenital vaginal septums were at fault. Absence of the vagina is not discussed. Secondary introital dyspareunia (20 per cent) resulted from menopausal shrinkage, too tight plastic or episiotomy repair or kraurosis. Deep dyspareunia arose from retroflexion with prolapsed ovaries, deep pelvic inflammations, parametritis, exudates, adnexitis and endometriosis. Combined introital and deep dyspareunia occurred in 37 patients.

Normal pelves were noted in 63 patients. Fifty-five per cent of these women showed neuroses and psychoneuroses; this was in sharp contrast to the percentage of the total figure (349), which was only 25 per cent.

In psychogenic dyspareunia the initial local or general factors may disappear, leaving no trace of any initial local causation (64 per cent); in the remainder some inciting local cause was still determinable.

The husband problem predominated in 36 cases. Most probably it was an important factor in many more.

In primary and secondary dyspareunia, local therapy combined with enlightenment and orientation proved effective.

In psychogenic dyspareunia great caution must be exercised in attempting to treat dyspareunia of long duration. The attitude of the patient is decisive; only those who manifestly wish to be cured should be treated. Those in whom the defense and resistance complexes predominate should be left undisturbed and if possible referred to a competent psychiatrist for preliminary treatment.

ECTOPIC PREGNANCY

W. D. BEACHAM, M.D.
CONRAD G. COLLINS, M.D.
E. PERRY THOMAS, M.D.
and
DAN W. BEACHAM, M.D.
New Orleans

"The history of the recognition of pregnancy proceeding outside the cavity of the uterus, the gradual understanding of its gravity and the development of modern methods of its treatment, forms one of the most fascinating episodes in that epitome of human intellect, its brilliancies and its lamentable failures, the history of medicine." So wrote Schumann¹ in his excellent monograph published over a quarter century ago. He stated that the first recorded case appeared in Bauhin's "*Gynaecorum sive de Mulierum Affectibus Commentarii*" (1586), being credited to Albucasis, an Arabian physician who practiced in Spain about the middle of the eleventh century. In 1604 Riolan described the classic picture of ruptured eccyosis; however, over a century elapsed before Dionis (1718) presented his commendable discussion on etiology. In 1759 Bard of New York operated in a case of abdominal pregnancy, the first type of ectopic gestation to be treated surgically. By 1876 Parry had collected 500 cases of extrauterine cecyosis with a mortality of 67.2 per cent. Seven years later Tait performed what is considered the first deliberate operation for ruptured tubal pregnancy. In the same year (1883) Briddon so operated in the United States.

During the twentieth century the literature on this subject has become voluminous, but few articles present a series of more than 300 cases from a single institution. In the last twenty years papers on ectopic pregnancy have been presented in this section by Behney,² Echols,³ Brown and von Graff⁴ and Schaeffler.⁵

The number of proved cases of ectopic pregnancy managed at the Charity Hospital of Louisiana at New Orleans since Jan. 1, 1906 has exceeded the thousand mark; consequently, it was logical to conclude that some of the data derived from the perusal of these records would prove appropriate at this centennial meeting. Although our institution celebrated its hundredth anniversary in 1933,⁶ records prior to 1906 are not available. Previous reports on this subject from the New Orleans Charity Hospital include those of Graffagnino,⁷ whose study covered the years 1906 to 1919, Graffagnino Seyler, and Bannermann,⁸ who brought certain statistics up through 1936, and Tyrone, Romano and Collins,⁹

From the Departments of Gynecology and Obstetrics of Tulane University School of Medicine and the Charity Hospital of Louisiana at New Orleans.

who were chiefly interested in the mortality rate from 1924 to 1934. This dissertation includes data derived from investigation of the entire series of 1,059 cases with limitation of certain details to the cases of the last ten years, inasmuch as the records of that period are far superior to those of the preceding years. The figures do not include instances of abdominal pregnancy,

Fig. 1.—Racial comparison of the incidence of ectopic pregnancy at the Charity Hospital at New Orleans.

because that type of ectopic gestation is so important that it is worthy of individual consideration. Such a review may be found in the December 1946 issue of *Obstetrical and Gynecological Survey*.¹⁰

RACIAL INCIDENCE

As shown in the first composite graph (fig. 1) the incidence is compared racially and in relation to deliveries and gynecologic admissions at the New Orleans Charity Hospital in the last forty years.

In the first decade there were 51 white and 49 Negro women with ectopic gestation among 2,048 white and

Fig. 2.—Age incidence among Negro and white patients.

2,769 Negro women delivered. The incidence was 2.5 per cent for the white patients and 1.77 per cent for the Negro. In the same period there were 6,470 white and 5,995 Negro gynecologic admissions, resulting in an incidence of 0.79 per cent for the white and 0.82 per cent for the Negro.

During the second decade 100 instances of extrauterine pregnancy occurred among white and 125 among Negro women, with 3,583 white and 6,370 Negro births, giving the figures of 2.79 per cent and 1.96 per cent, respectively. There were 9,077 white and 11,188 Negro gynecologic admissions, with an incidence of 1.11 per cent for both races.

The third ten year period had 161 cases among white and 192 among Negro patients, 9,336 white and 18,063 Negro deliveries and 22,643 white and 24,147 Negro gynecologic admissions. The incidence among white and Negro patients was 1.78 per cent and 1.11 per cent for the former group and 0.73 per cent and 0.82 per cent for the latter.

Since 1936 there have been 134 cases among white and 247 among Negro patients, with the delivery figures reaching 13,985 and 40,023, giving an occurrence of 0.95 per cent and 0.59 per cent. The number of gynecologic admissions has increased to 23,874 white and 28,479 Negro, causing a percentage of 0.55 and 0.84.

Fig. 3.—Previous pregnancies.

It should be pointed out that during the first two decades the white obstetric patients consisted largely of those with complications, whereas during the second twenty years more and more patients with normal pregnancy have been admitted, so that the incidence of 0.95 per cent begins to approach the true incidence of ectopic cyesis to term intrauterine gestation. This is more evident among the Negro race, as is indicated by the incidence of 0.59 per cent in the last decade, when 40,023 Negro deliveries, representing over three fourths of those for New Orleans, occurred in our institution. In the future the actual relation to deliveries as recorded by hospital checks will be more accurate, inasmuch as more and more obstetric patients will be institutionalized.

In the last forty years there has been a sharp increase in the gynecologic admissions to Charity Hospital; however, the frequency of ectopic pregnancy has varied little. Even though the number of cases of extrauterine gestation is larger for the fourth decade, the percentage occurrence is the lowest during the entire period of this study. When one compares the gynecologic admissions, one notices that the incidence is higher in the Negro race, as one would expect in our locality, since the incidence of salpingitis is higher in this race.

AGE

Inspection of figure 2, which is computed on the basis of 100 per cent for each race, reveals that the majority of ectopic pregnancies in the Negro group in this series occurred between the years of 21 and 30, whereas for the white group the greatest incidence was found in the 26 through 35 age range. The youngest white patient was 16 years of age and the eldest 42. The age limits for the Negro patients were 15 and 48 years.

PREVIOUS PREGNANCIES

Only 66 of the 381 patients comprising the series from 1937 to 1946 had not been previously pregnant, as is shown by figure 3. Excluding the extrauterine gestation which caused them to come to the hospital, there were 62 primigravidas, 69 secundigravidas and 52 tertigravidas. Somewhat unexpectedly, we found 17 septigravidas.

Of those who had been gravid once or more, 34 had failed to carry a fetus to the stage of viability; 88 had carried one gestation near or to term, 62 were secundiparas and 37 were tertiparas.

Twenty-six gave a history of one abortion; 7 admitted two abortions, and the remaining 55 had undergone three or more abortions, one having a total of thirteen.

Thirteen (3.4 per cent) of the patients during the last decade had undergone proved previous ectopic pregnancy, the majority having been managed at Charity Hospital. This percentage is almost identical with that reported by Smith,¹¹ who found an incidence of 3.6 per cent among 1,608 patients operated on by members of the American Gynecological Society, and by Mason and Storrs¹² in their study of 400 cases of extrauterine pregnancy. Also, we found, as did Fitzgerald and Brewer¹³ in their study of 500 cases, 402 of which were managed in Cook County Hospital, that a long period of sterility preceding the extrauterine pregnancy was not the rule in this group.

In 750 cases the tube involved was found to be the right in 60.1 per cent and the left in 39.9 per cent. The tubal site most commonly found was the ampulla, next often the isthmus and least often the interstitial portion.

Of these tubal pregnancies 12.8 per cent were intact, 70.8 per cent were ruptured and 16.4 per cent were classified as abortion.

Fig. 4.—Chief complaint. A, pain, 67.8 per cent. B, bleeding, 8.9 per cent. C, weakness, 3 per cent. D, pain and bleeding, 20.3 per cent.

2 cases of bilateral tubal gravidity. Although the diagnosis of ovarian pregnancy has been made at the New

Orleans Charity Hospital several times, only 1 case record meeting all of the prerequisites for such a designation could be found by us.

Of the patients treated in the past decade 69 (18.1 per cent) had been subjected to previous surgical treatment of the lower part of the abdomen, the most frequent procedure being appendectomy.

As confirmed by the pathologists, 134 (36 per cent) patients had salpingitis. No instance of salpingian tuberculosis was found.

The infrequency of recorded tubal malformations and evidences of obstruction due to tumors in this series is conspicuous.

CHIEF COMPLAINT

In this study it was noted that 67.8 per cent of the patients presented a chief complaint of pain; 20.3 per cent complained chiefly of pain and bleeding, while 8.9 per cent complained of bleeding. Weakness was recorded as the major complaint in only 3 per cent of the cases. This confirms the widely accepted belief that pain or bleeding or a combination thereof is responsible for these patients' trips to the hospital. Nausea, vomiting, syncope and other secondary symptoms were often found in the histories, but these require no special discussion.

Only 8.8 per cent of the patients arrived at the hospital within twelve hours of the onset of the principal symptom; 12.3 per cent complained for one day and 4.4 per cent for two days; 17.2 per cent gave a duration of one to two weeks, 27 per cent two weeks to two months and 1.57 per cent had complained for four to five months.

The pain of ectopic pregnancy may vary considerably, depending on the status of the embryo, the intactness of the salpinx, the amount of hemorrhage and the threshold of the individual. Figure 5 reveals that 43.9 per cent of the patients experienced pain in the lower part of the abdomen, 30.3 per cent in the right lower quadrant, 17.5 per cent had it in the left lower quadrant and in 8.3 per cent it was recorded as abdominal. Of the records disclosing the location of the pain in one of the lower quadrants there was an accurate correlation with the ectopic in 79 per cent. Pain in the shoulder occurred in 15.3 per cent. The onset was sudden in 68.2 per cent and gradual in 31.8 per cent of the cases. In 69 per cent it came without exertion, but in 31 per cent it appeared during exertion. In 44.9 per cent of the latter group, the patient was in the bathroom. The severity was classified as mild, 4.8 per cent, moderate 11.8 per cent and marked 83.4 per cent. It was intermittent in 85.1 per cent and continuous in 14.9 per cent.

Fig. 5.—Pain. The onset is gradual in 31.8 per cent of the cases, sudden in 68.2 per cent; the onset is with exertion in 31 per cent of the cases, and without in 69 per cent; the pain is mild in 4.8 per cent of the cases, moderate in 11.8 per cent and severe in 83.4 per cent; it is continuous in 14.9 per cent of the cases and intermittent in 85.1 per cent.

LAST MENSTRUAL PERIOD

Data regarding the last menstrual period is of great importance in making the diagnosis of ectopic gestation. According to the records 1.71 per cent of the patients were having what they considered a "regular menstrual

11. Smith, R. R.: Repeated Ectopic Pregnancy, *Am. J. Obst.* 64: 401, 1911.

12. Mason, N. R., and Storrs, R. W.: An Analysis of Four Hundred Cases of Extra-Uterine Pregnancy, *Boston M. & S. J.* 189: 914, 1923.

13. Fitzgerald, J. E., and Brewer, J. I.: Extra-Uterine Pregnancy, *Am. J. Obst. & Gynec.* 50: 264, 1935.

period" at the time of hospital entry. Four and seven-tenths per cent stated that the last menses occurred two weeks prior to admission; 5.9 per cent, three weeks and five weeks. Six and eight-tenths per cent had amenorrhea for four weeks; 9.95 per cent six weeks and 9.11 per cent seven weeks. The greatest percentage

Fig. 6.—Last menses.

(18.5 per cent) gave a history of amenorrhea for two months. The figures then fell at the ninth and tenth weeks to 8.3 per cent and 4.27 per cent, respectively. After dropping of the percentage to 1.99 for an amenorrheic period of eleven weeks, a precipitous rise to 14.3 per cent was found for the three month group. Three and thirty-nine hundredths per cent observed their last menstrual period four months previously, and 0.57 per cent seven months, as is shown by figure 6.

Estimation of the duration of the pregnancy from the menstrual history and gross observations reveals that rupture tends to occur earlier in the isthmus of the salpinx than in the ampulla.

In the study of the records of the last ten years in 32 instances without rupture or tubal abortion, in only 4 was there no abnormality of uterine bleeding. The remainder exhibited amenorrhea and/or "spotting." Two cases of "flooding" were attributed to associated conditions. From the historical viewpoint one may confuse the "spotting" case with threatening uterine abortion, while the ones presenting "flooding" are apt to be misdiagnosed as incomplete abortions, myomas or ovarian cysts.

In this group tenderness was found to be the most important sign (table 1). In over 90 per cent it was of the abdominal type. In 80 per cent cervical manipulation resulted in pain. At the time of admittance bleeding via the vagina was present in 76.8 per cent. An adnexal mass was recorded as being palpable in 43.3 per cent. The location of the ectopic pregnancy was stated in 31 per cent with an accuracy of 87.6 per cent. The contents of the cul-de-sac were regarded as abnormal in 39.6 per cent.

In 13.6 per cent of the cases exhibited there were signs of shock at the time of admittance. In 6.8 per cent shock developed after entrance into the hospital.

In this connection it is well to point out that even though the history is of prime importance in the diagnosis of ectopic gestation the patients should be given the benefit of a careful pelvic examination. Such an investigation must be performed with an understanding degree of gentleness in order to prevent the rupture of a gravid tube or to aggravate bleeding. Undoubtedly many patients that have been discharged from hospitals with a diagnosis of threatened abortion and later returned with rupture of a tubal pregnancy would have received a correct diagnosis if they had been properly examined. Consequently, it is our belief that patients suspected of having threatening, threatened, incomplete or missed abortions should be carefully examined.

Two hundred and forty-six patients had temperature under 99 F.; 53 from 99 to 100; 14 from 100 to 101, and 15 over 101. In the cases in which the temperature was above 102 F., some cause other than the ectopic pregnancy per se was found.

DIAGNOSTIC PROCEDURES

In cases in which tubal pregnancy with intra-abdominal bleeding is suspected and in which the observations are not conclusive enough to justify laparotomy puncture of the cul-de-sac should be done. This procedure was employed in 74 cases during the past ten year period. In 69 cases the result of the test was considered positive and most of the patients promptly operated on. In 5 instances the puncture was interpreted as being negative in result, although blood was found in the abdomen shortly after the colpocentesis.

Considerable has been written about the value of sedimentation rates in the diagnosis of this condition. Such a test was performed in 234 cases with the expected results in most instances. Obviously, tests which allow for the correction of attending anemia are of much more value than the old ones. For 74 patients one or more hematocrit determinations were obtained. Such readings are an excellent means of determining the degree of activity of suspected internal bleeding.

In this study it was found that leukocyte counts were of little value in differentiating extrauterine gestation from inflammatory conditions.

The Friedman-Lapham test was employed in only 28 cases. In 22 of these the result was positive and in 6

negative. Suffice it to say that a positive report is of definite value, whereas a negative one calls for reconsideration of the history and physical findings; it should be remembered that hormonal tests for pregnancy are positive in result only if there are living chorionic villi.

Cervical dilatation and uterine curettage were performed in 10 cases, indicating an attempt on the part of the operator to rule out the possibility of incomplete uterine abortion. In all 10 cases laparotomy was done.

PREOPERATIVE DIAGNOSIS

Our perusal of the records shows a progressive increase in the degree of accuracy of the preoperative diagnosis of ectopic pregnancy at Charity Hospital. In the period 1906 through 1920 only 44 per cent had an accurate opinion. In the next group 62 per cent had a correct diagnosis and in the last group, 1937-1946, 82 per cent were properly diagnosed as indicated by figure 7.

Myomas were responsible for inaccuracy in 5.9 per cent of the cases; in the majority of these uterine fibroids were present in addition to ectopic pregnancy. In 4.2 per cent pelvic inflammatory disease was recorded, whereas the main diagnosis should have been extra-uterine cyesis. In 1.6 per cent the patients were scheduled for appendectomies. In a similar percentage the condition was diagnosed as being an abortion. Various and sundry diagnoses were recorded in 2.3 per cent. Litzenberg¹⁴ has pointed out the fallacy of depending on so-called cardinal symptoms in the diagnosis of ectopic pregnancy, inasmuch as so many of the cases are atypical.

In 133 of the last 373 operative cases, salpingectomy was done. A bilateral salpingectomy was performed twelve times. One hundred and seventy patients were

subjected to salpingo-oophorectomies. Hysterectomy was done in 63 cases; in 46 it was of the supracervical variety, in 13 abdominal total and in 4 vaginal in type. In most instances in which hysterectomy was done the adnexa were removed. Appendectomy was performed forty-one times and other abdominal operations including hysteropexies were performed in 14 cases (table 2).

The number of operators was one hundred and nine, a large majority being residents. In this connection it is well to point out that the extent of the surgical treatment should be governed by the condition of the patient and the observations. Obviously, if the patient is in shock or near the shock level, minimal surgery for cure of the ectopic gestation should be employed. On the other hand, if the patient is in good condition and there is little or no blood in the abdomen the operator will do well to perform any indicated operation. None of these patients subjected to surgical treatment for associated conditions died.

Sixty-nine of the last 373 patients operated on had spinal analgesia; 24 had ethylene anesthesia alone and 96 received cyclopropane; 184 were anesthetized with ether after induction with a gas. The type of analgesia and/or anesthesia should be determined by the condition of each patient.

POSTOPERATIVE CARE

The recovery of patients with ruptured tubal pregnancy is usually rather dramatic. Measures for the relief of pain are required. In this series most of the

patients were catheterized postoperatively. Fifty-one had suction for the relief of abdominal distention. Oxygen was administered to 31 patients. The maximum postoperative temperature was on the first postoperative day in 224 cases, on the second in 74 and the third in 25. The maximum temperature did not exceed

Fig. 7.—Preoperative diagnosis.

101 F. in 207 cases. It was from 101 to 102 F. in 94 cases, 102 to 103 F. in 30 cases, 103 to 104 F. in 14 cases and exceeded 104 F. in only 5 cases. Infusions and transfusions should be given postoperatively as indicated. Wound disruption occurred in 5 cases (1.4 per cent). There were 10 wound infections (2.7 per cent).

MORTALITY

Williams and Corbit¹⁵ analyzed 101 fatalities from ectopic pregnancy, finding that the ratio of ectopic deaths to puerperal deaths is twice as high in Negroes as in the white race.

Fig. 8.—Mortality of ectopic cyesis.

In figure 8 each bed and erect figure represents 20 cases. A cross indicates 2 cases. One bottle symbolizes 10,000 cc. of blood. In the ten years following the revision of the staff and the institution of the residency system at the New Orleans Charity Hospital only 2 deaths occurred among white and 9 among

14. Litzenberg, J. C.: Some Fallacies in Regard to Ectopic Pregnancy, South. Surgeon 6: 2, 1937.

15. Williams, P. F., and Corbit, J. D.: An Analysis of One Hundred and One Fatalities from Ectopic Pregnancy, Am. J. Obst. & Gynec. 48: 841, 1944.

Negro patients, resulting in an absolute mortality rate of 2.89 per cent. During this time 250 patients were given a total of 239,100 cc. of blood.

Of the deaths there were 5 which could not have been prevented by the hospital staff. Two patients died within five minutes of their arrival. One was brought into the admitting room in profound shock and died while receiving a blood transfusion and while preparation was being made in the operating room for immediate surgical treatment. Another was found to have generalized peritonitis, although she was operated on promptly. The fifth patient died because of massive cerebral apoplexy. At autopsy she was found to have a six month intrauterine pregnancy with an old unruptured noninfected tubal cystis.

There were 6 preventable deaths. One patient remained in the admitting room for one hour and forty-five minutes without receiving blood or being treated surgically. Another died of shock while enroute to the operating room five hours after admission, although the admitting diagnosis was correct. She received only infusions, as blood was not available. A third died during the night ten hours after hospital entry because of inaccurate diagnosis. Death of the fourth, also due to hemorrhage, occurred after two days of hospitalization with repeated transfusions. The fifth patient was operated on and died three days later of pneumonia, for which she was inadequately treated. Death of the last patient was attributable to obstruction of the sigmoid colon on the twentieth postoperative day.

With these data taken into consideration the corrected mortality would be 1.3 per cent. Of the emergency patients it is important to point out that very few had sought medical advice. Their dire state at the time of admission must be blamed on procrastination, as one would expect of patients who are eligible for admittance to a strictly charity hospital.

CONCLUSIONS

One thousand and fifty-nine cases of proved ectopic pregnancy, excluding the abdominal type, have been managed at the Charity Hospital of Louisiana at New Orleans since Jan. 1, 1906. Four hundred and forty-six white and 613 Negro patients constitute the series, the incidence being higher in the Negro race.

The majority of cases in the Negro group occurred between the ages of 21 and 30 years, whereas for the white group the greatest incidence was in the 26 to 35 age range. The white age limits were 16 and 42, while for the Negroes they were 15 and 48.

Only 17.3 per cent of the patients during the last decade had not been previously pregnant. Three and four-tenths per cent of the patients had undergone proved previous ectopic pregnancies.

Of 750 instances with recorded tubal location 60.1 per cent were on the right and 39.9 per cent were on the left.

The chief complaint was pain, pain and bleeding or bleeding in 97 per cent of the cases. Even unruptured and unaborting tubal pregnancies in this series presented abnormal uterine bleeding in the majority of instances.

Although ectopic cystis can lead to rapid death, in the majority of cases abnormalities are observed for many days.

The clinical picture of tubal pregnancy is so typical in many cases that diagnosis is easily made. In others a carefully obtained history and thorough examination of the patient are necessary to prevent diagnostic errors. Puncture of the cul-de-sac, hematocrit determinations,

hormonal tests for pregnancy, blood studies and other procedures must be regarded in the role of aids in diagnosis subject to intelligent interpretation. In certain cases colpocentesis is of great value.

In our institution the residency system, a revision of the visiting staff and the adequate administration of blood have greatly reduced the mortality of this condition.

Working with strictly charity patients at the South's largest hospital causes us to appreciate that education of the patient and early and adequate prenatal care will reduce the mortality and morbidity figures of ectopic gestation.

ABSTRACT OF DISCUSSION

DR. T. J. WILLIAMS, University, Va.: Dr. Beacham's figures confirm the importance of the triad of symptoms of tubal pregnancy: abnormal menstruation, abdominal pain and slight vaginal bleeding. The diagnostic accuracy of 82 per cent is an excellent record. These figures on diagnostic accuracy, however, present only one side of the picture and do not show those instances in which extrauterine pregnancy was diagnosed and not found. Obviously on this basis a 100 per cent accuracy could be obtained by diagnosing extrauterine pregnancy in every gynecologic patient before operation. It is surprising that myomas accounted for the highest number of incorrect preoperative diagnoses. In our experience salpingo-oophoritis and abortions have been most frequently confused with ectopic pregnancy. We agree with the essayist that patients under observation or treatment for abortions should have careful pelvic examinations done under aseptic precautions to rule out ectopic pregnancy. The possibility of extrauterine pregnancy must be constantly borne in mind. We consider every early abortion as a possible ectopic pregnancy until a pelvic examination has been done or the product of conception has been passed. A decidual cast which may be passed must not be confused with placental tissue. The presence of decidua and an absence of chorionic villi on microscopic examination of the tissue which has been passed would establish the diagnosis of ectopic pregnancy. Cul-de-sac aspiration or posterior colpotomy are helpful procedures in distinguishing between blood and inflammatory exudates in the cul-de-sac. This, however, is not necessary in the majority of cases of extrauterine pregnancy. It is perhaps unusual that it was found necessary to remove the uterus in about 16 per cent of the last 373 cases of operation for tubal pregnancy, but, as the essayist has mentioned, the extent of the operative procedures must be governed by the condition of the patient and the amount of blood loss. Dr. Beacham's analysis points out the importance of the replacement of blood loss as a significant factor in the reduction of mortality in obstetric and surgical conditions associated with hemorrhage. The mortality of 2.89 per cent in the 381 cases during the last nine years, in comparison with the mortality of 12.8 per cent in 490 cases during the previous fifteen years, is a dramatic improvement. While other factors such as early diagnosis, early operation, improved anesthesia, chemotherapy and antibiotics have played their part in the improved mortality figures, I dare say that the most significant factor has been the adequate replacement of blood loss.

DR. CHARLES A. BEHNEY, Philadelphia: In our series the percentage of accurate diagnoses was only 61.3 per cent as compared to 82 per cent accurate preoperative diagnoses in Dr. Beacham's series. In our series from the University Hospital, disease of the opposite adnexa, such as salpingitis, perisalpingitis, pyosalpinx, hydrosalpinx or hematosalpinx, occurred in only 22 per cent. Assuredly there must be some other factor in the causation of this disease. Since tubal pregnancy is normal in lower animals, it occurred to us that perhaps a reversal to the lower forms, manifested by infantile uteri or acute anteversion of the uterus, might explain some of these cases. With this in mind, we investigated the frequency of anteversion of the uterus and delayed onset of menstruation. Anteversion of the uterus was reported present in 76 per cent of our series, and menstruation was established later than the fourteenth year in 32 per

cent of the patients. So far as the ages of the patients and previous pregnancies are concerned, Dr. Beacham's statistics coincide with ours. In this report, 60 per cent of the lesions occurred in the right tube. In the University series, 53 per cent occurred in the right tube and 46 per cent in the left. The patients with combined intrauterine and extrauterine pregnancy are of great interest, as are those in whom both tubes were involved coincidentally. I subscribe heartily to Dr. Beacham's diagnostic procedures. A careful history and accurate pelvic examination are of utmost importance. When doubt as to the findings exists, puncture of the cul-de-sac with the needle and colpotomy are the diagnostic procedures of the greatest value. If blood is not discovered in the cul-de-sac, the adnexa can be inspected through the colpotomy wound, and sometimes hemorrhage may be arrested through this approach without resort to laparotomy. Extrauterine pregnancy can be divided into three categories: urgent, nonurgent and obscure. In the urgent cases the condition is easily recognized. The nonurgent cases are those in which the symptoms may simulate other acute pelvic diseases. It is better in these instances to delay operation until every pertinent test can be made. In the obscure group are the patients who have missed three or more periods, in whom the primary condition of extrauterine pregnancy has been followed by secondary abdominopelvic pathologic changes, frequently resulting in extragenital symptoms which lead to hospitalization. The signs and symptoms of the original lesion are never recognized at the onset, and they are subsequently masked by the secondary pathologic changes. May I refer to Polak's warning against multiple operations, especially in the presence of intraperitoneal hemorrhage. When operating for extrauterine pregnancy close the abdomen as soon as the bleeding has been arrested.

DR. CHESTER M. ECHOLS, Milwaukee: Being older than most of you, I can recall vividly an episode which occurred in this section forty years ago this month—that is, in June 1907. At that time the late Dr. Hunter Robb startled the members of our section by advising us never to operate for ruptured ectopic pregnancy while the patient is in the acute hemorrhagic stage of shock. His advice was based on extensive experimentation with animals. He had done a laparotomy on 30 bitches, and deliberately severed the ovarian arteries, then sewed up the abdominal incision and waited to see what would happen. Not one of the animals died of hemorrhage. Hence his advice to wait for the shock stage to pass before operating for ruptured tubal pregnancy. Not since the days of Lawson Tate had there been any advice or proposal so revolutionary in the management of ectopic pregnancy. Within the next few years doctors throughout the land began to learn that women with ruptured tubes not only can but sometimes do bleed to death. In a paper which I read before this section in 1934 on ectopic pregnancy, I ventured the prediction that the time would probably never come when more than 70 to 80 per cent of correct diagnoses would be made before operation. In New Orleans, as you have just heard from Dr. Beacham, they have somewhat exceeded that figure, and I want to compliment them on doing so; but for obvious reasons there is not likely to be much improvement over the figures just heard, because the pathologic changes involved are so varied that the symptoms must likewise be varied, and it is difficult to lay down any hard and fast rules for diagnosis. To date I have had in my private practice one hundred and twenty-three operations for ectopic pregnancy, without a death. But with all that experience I missed the diagnosis in my last 2 cases. Maybe it was because the patients were unmarried women. But that is a poor alibi.

DR. IRVING F. STEIN, Chicago: I wish to emphasize the point made by the essayist that the early diagnosis of unruptured ectopic pregnancy is extremely important. Any method which will facilitate the early diagnosis of this condition should be utilized. For a number of years, I have used gynecography in gynecologic diagnosis and in selected cases of ectopic pregnancy have successfully employed this method. In differentiating intrauterine pregnancy with the symptoms of threatened abortion, corpus luteum cyst and unruptured tubal pregnancy, gynecography serves as a valuable diagnostic aid. It is a simple and safe diagnostic procedure.

DR. B. BERNARD WEINSTEIN, New Orleans: I should like to commend Dr. Beacham on his fine presentation and underscore his plea for conservatism in the salvage of the ovaries. I should like to enter a plea for the possible salvage of an occasional tube. Some of these are tubal abortions. We see much blood; we are all in too much of a hurry, sometimes, to remove the tube on the involved side. With good anesthesia, good preoperative preparation, with blood banks available and blood in use, there is no need for the great hurry which once characterized this procedure, and we can take an extra few minutes to inspect these tubes carefully. Every now and then there is one that can be salvaged. We have had two in the past three years. We were able to secure the bleeding points and reach to the tubes. This was done because the patient had the other tube out in 1 case for a previous inflammatory disease, and in the other for a previous ectopotomy for tubal pregnancy. These patients have been followed. Tubal insufflation was done a month later. These women have good tubes, and in 1 case a pregnancy. I do not mean to say that this should be a routine thing. I heartily subscribe to the fact that the tube in the vast majority of instances must be removed. But every now and then, if we are not in too much of a hurry, we can salvage not only the ovaries but an occasional tube.

SURGICAL TREATMENT OF CANCER OF THE RECTUM AND RECTOSIGMOID

FRED W. RANKIN, M.D.

and

COLEMAN C. JOHNSTON, M.D.
Lexington, Ky.

Cancer of the rectum is an easily diagnosed lesion which when extirpated radically by surgical methods has a most favorable prognosis. While there is small difference of opinion that radical surgery is the method of choice in its treatment, the rediscovery of the "pull through operation" has in recent years created a certain amount of controversy as to the type of procedure most acceptable in the majority of cases. A cursory survey of the literature of a quarter of a century ago would have revealed to the most ardent enthusiast for the sphincter-saving type of operation a paucity of data on favorable end results of such attacks.

In this day and generation of intense haste and progress in the many fields of scientific endeavor, one is often prone to rationalize more than is justified, in order to keep pace with rapidly moving trends. New methods are devised from old ideas which have lain dormant for years, while others which have been discarded because of inadequacy or outmoded by more practical developments are now being revived.

Certainly the milestones of progress in the treatment of cancer of the rectum and sigmoid colon, beginning as long ago as 1826 and labeled with the name of the Frenchman Lisfranc, have created an interesting vista of experience on which to look back. As one reaches the horizon of present day surgery of the lower bowel, one finally views the work of Miles as the greatest contribution in this field of surgery which has yet been made. The combined abdominoperineal resection of the rectum as developed by him has yet to be improved on by any surgeon of this day.¹

¹Read before the Section on Surgery, General and Abdominal, at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

1. Miles, W. E.: A Method of Performing Abdominal-Perineal Excision for Carcinoma of the Rectum and of the Terminal Portion of the Pelvic Colon, *Lancet* 2:1812, 1908.

Since Miles's epic publication there have been innumerable surgeons both great and small who have tried to develop many procedures for the preservation of the anal sphincter in the treatment of cancer of the rectum. In the light of the recent anatomic studies of the lymphatics of the perirectal and pelvic tissues carried on by David and Gilchrist² and again by Collier and Ransom,³ there seems little justification for this effort. Furthermore, there has been to date no reported series of five to ten year cures of cancer of the rectum with preservation of the anal sphincter which can compare with the results achieved by the Miles operation.

In the light of the extensive and painstaking work of David and Gilchrist, who have studied an average of fifty-five glands per specimen in 200 resections, our routine pathologic studies in most instances seem rather inadequate. They do, however, lend additional evidence to the thesis that the presence or absence of glandular involvement exerts a profound influence on prognosis. It is the best yardstick in determining prognosis. It shows that longevity is in direct proportion to glandular involvement. This, in turn, is entirely dependent on the grade of the growth. In short, the lower the grade of the lesion, the later metastasis will occur. In contrast to this, the higher the grade, the earlier extension will take place. These observations emphasize the fundamental importance of as radical an operation as possible with as widespread a removal of gland-bearing tissue—a basic surgical principle.

The bitter cry against the abdominal anus as pointed out by Pfeiffer⁴ is raised by "those who do not have them and do not need them to remain alive." Again, he observed that "of course, the uncontrollable perineal colostomy is infinitely inferior to the abdominal anus in all respects except sentimental nonsense." With this thesis the great majority of surgeons who have had wide experience in this field are in hearty accord. By contrast one finds a few men in this country and abroad who persist in trying to stem the tide of current thought by expending great effort to maintain the anal sphincter or condone the tragic incapacity of an incompetent perineal colostomy.

The secret of proper adjustment to an abdominal colostomy is the realization that this is the safest and best method of insuring longevity. The surgeon who is a staunch advocate of the combined operation as the best possible means for saving the life of his patient will not belie the confidence of his patient in a faltering dissertation on the pros and cons of an abdominal anus versus perineal colostomy or the doubtful possibility of retaining the use of the anal sphincter. It is this uncertainty that a colostomy is essential which leads to hesitation, dissatisfaction and maladjustment.

We have with persistent interest followed the course of our patients who now wear a colostomy. To each one the necessity of the procedure is carefully explained prior to operation, and thereafter the routine colostomy care is quickly made a part of the patient's responsibility. Firm but patient gentle instruction and kindly encouragement do much to hasten the psychic readjustment of even the highly emotional and unstable patient. We have had no psychoses or suicides which have resulted from the inability to adjust to wearing a colostomy.

CHOICE OF OPERATION

- I. Combined abdominoperineal, one stage, Miles.
- II. Colostomy and perineal resection, Mummery.
- III. Local resection without colostomy, Harrison-Cripps, Quénu, Tuttle, etc.
- IV. Operation preserving the sphincteric mechanism.

I. Combined Abdominoperineal Operation, One Stage.—The operation of choice, we believe, for cancer of the rectum is the Miles combined abdominoperineal resection in one stage. This operation has many advantages:

1. It permits ligation of the blood supply to the rectum before the pelvic dissection is carried out.

2. It permits a widespread removal of gland-bearing tissues in all zones of spread, particularly the upward zone of spread into the mesentery of the sigmoid. It is futile to argue that because there are few recurrences in the downward and lateral zones of spread one may practically ignore them in selecting an operation for cancer of the rectum. Only this year I have seen 2 cases of recurrence in the posterior vaginal wall following the radical combined operation; 1 which was handled by me and the other by a colleague of mine, three and four years ago, respectively. This downward spread is corroborated in a recent article by David and Gilchrist, who reported in their series 7 cases in which the metastatic glands were found below the primary growth, the involved glands being found as much as 5 cm. distal to the margin of the tumor.

It is essential that any operation for cancer which lies in juxtaposition to the levator ani be radical enough to remove the levator ani and the fat and glands in the ischiorectal fossa.

3. Statistical studies up to now have indicated without exception that the Miles operation gives a higher percentage of three and five year cures and of freedom of recurrence than any other type of procedure available.

4. While the operation bears the inconvenience of a colostomy, it should be emphasized that a colostomy is not a stigma but an inconvenience. A colostomy definitely does not entail social ostracism or professional incapacity. It may limit activities, true, but only that.

With the steady improvement in preoperative preparation, in anesthesia and postoperative care, more and more patients, including the elderly, the feeble and the depleted, are being submitted to the radical resection in one stage with a lower mortality and higher curability rate.

II. Colostomy and Posterior Resection (Mummery).—This operation is a useful procedure in certain desiccated, devitalized and depleted patients on whom one hesitates to do the Miles operation. It is a more conservative procedure which does not allow the radical removal of the large portion of mesentery and, in addition, is divided into two stages. Its utility is steadily decreasing and in the past few years only an occasional patient has been submitted to this type of procedure in our service.

III. Local Resection Without Colostomy (Harrison-Cripps, Quénu, Tuttle, etc.). Local resection without colostomy in the form of such procedure as devised by Harrison-Cripps, Quénu, Tuttle and others is useful in a limited group of cases. These operations, however, have a definite place, small though it may be, in the surgeon's armamentarium.

2. David and Gilchrist: Personal communication to the authors.

3. Collier, F. A., and Ransom, H. K.: The One Stage Procedure of the Treatment of Carcinoma of the Rectum, *Tr. Am. S. A.* 54: 163, 1936.

4. Pfeiffer, D. B., in discussion on Hordley, J. S.: Resection of Recto-sigmoid and Upper Rectum for Cancer with End-to-End Union, *Surg., Gynec. & Obst.* 64: 313, 1937.

IV. *Sphincter-Saving Procedures.*—Without personal experience with the "pull through operation" but with a knowledge of the meager literature on long time cures following its employment, I find small opportunity for its consideration at all if the growth is below the peritoneal fold. The difficulty in standardizing a nomenclature for the rectosigmoid juncture leads to confusion, but any sphincter-saving operation for a cancer below the peritoneum certainly is excessively vulnerable. When the cancer is entirely intraperitoneal but low down—say within 2 inches (5.1 cm.) of the peritoneal fold, an anastomosis, open or closed or by David's obstructive method, can be employed in favorable cases with satisfaction. But it is an entirely different consideration when one attempts to anastomose the bowel for a carcinoma within 3 inches (7.6 cm.) of the sphincter muscle.

The technical procedure of sewing together two pieces of bowel low in the pelvis is not a difficult thing for a skilled operator, but it is certainly not a triumph to make an anastomosis and save mesentery which contains involved glands. Sentiment for the sphincter muscle is hardly a logical reason for selecting an operation. The true measure of a procedure is the longevity curve. The recognition that vital organs and mechanisms must be sacrificed in an operation to eradicate cancer is not new. Operations on the breast, jaw, tongue and in many other locations are frequently mutilating procedures, but the necessity of their employment has long since been established. Why should a different principle be applied to cancer of the rectum?

PREOPERATIVE AND POSTOPERATIVE CARE

Among the important strides which have been made in the past two or three decades is the development of a more profound insight into the physiologic reserve of the patient about to be operated on. This feature alone has done more to prevent postoperative complications and to reduce the operative mortality than any other single development including advances in technics. One cannot overemphasize the importance of a careful and thorough preoperative study and preparation of patients with cancer of the large bowel. Too often such a lesion, though subtle and insidious in its development, will cause a slowly progressive but pronounced anemia and protein deficiency. Continuous though small serum loss from the ulcerative lesion not infrequently leads to subclinical hypoproteinemia not always manifested by the serum protein evaluation. Mild to moderate vitamin deficiency is the rule rather than the exception, while dehydration of varying degree is not uncommon.

In order to determine individual requirements and correct existing deficiencies these patients are admitted to the hospital five to six days prior to operation. The routine examinations of blood and urine are made, in addition to which values for blood protein and non-protein nitrogen are determined. Blood protein levels are raised to 6.5 Gm. per hundred cubic centimeters. Nitrogen, caloric and electrolytic balance is established. Transfusions are used to combat the existing anemia. A fluid intake up to between 3,000 and 4,000 cc. is encouraged for each twenty-four hour period, and a high value polyvitamin preparation is given with each meal. Twice daily the bowel is irrigated with copious washings of isotonic solution of sodium chloride until

the returns are clear. The day prior to operation the irrigation is carried out in the morning only and the bowel is put at rest with three doses of camphorated opium tincture, 2 drachms (8 cc.) given at four hour intervals. In the group of patients reported in this series the sulfonamide drugs were not administered preoperatively. They are being used now, as we believe them to be a valuable addition to the preoperative preparation. Immediately after operation a transfusion of 500 cc. of whole blood is given routinely. Thereafter, fluid, nitrogen, electrolytic and vitamin balance is maintained by parenteral administration of fluids, which include dextrose, plasma, isotonic solution of sodium chloride and vitamin concentrates. Penicillin was not available during the time that the reported series was accumulated, but now it is being used routinely for the first five days postoperatively. The colostomy clamp is removed on the second postoperative day, and as soon as healing is sufficient routine colostomy care is begun.

STATISTICAL STUDY OF A SERIES OF CASES

During a period of seven years, from 1934 to 1941, 336 patients suffering with cancer of the rectum and rectosigmoid were studied. Of this group 310 were

TABLE 1.—Operations for Cancer of the Rectum and Rectosigmoid

	Cases	Deaths	Mortality, %
One stage combined abdominoperineal resection	167	9	5.3
Colostomy and posterior resection.....	56	9	16.0
Posterior resection without colostomy	1	0	0
Two stage resection (Rankin).....	9	2	22.2
Exploration alone	19	3	26.3
Exploration with colostomy.....	54	17	31.5
Cecostomy (acute obstruction due to cancer)	4	4	1.0
310 cases, 233 resections.....			Resectability, 75.1%
233 resections, 167 one stage combined abdominoperineal resections			Applicability, 71.7%

subjected to operation, while for 26 it was felt that an operation was contraindicated. Of this entire group, in 167 patients the abdominoperineal resection of the rectum in one stage was performed with a mortality of 5.3 per cent. The two stage combined operation was utilized in 9 cases, while in 56 the colostomy and posterior resection were done. In 19 patients exploration revealed that no further procedure was indicated, whereas exploration and colostomy were done on 54 patients. In 1 patient a local excision was done, and in 4 cecostomy for obstruction.

Of this series of patients 212 were males and 124 females. Fourteen of the men were found to have inoperable cancer in contrast to 16 of the women, while one hundred and ninety-eight and one hundred and eight operations, respectively, were done in the two groups.

Of the entire group of patients 233 were amenable to resection of the lesion, giving a resectability rate of 75.1 per cent. The one stage combined abdominoperineal resection of the rectum was applicable to 167 patients, or 71.7 per cent of the group.

It should be noted that in 73 patients glandular metastasis was found to have already developed, whereas in 89 patients no glandular involvement was found. Of the 73 patients with glandular metastasis

27.3 per cent lived five years or longer while 10.9 per cent were alive and well under five years. In the group of 89 patients who were found to have no glandular involvement, 43.8 per cent survived the five year period while 24.7 per cent were living under five years. Over 61.6 per cent of those patients with glandular involvement died within the first five years following operation, while only 30.3 per cent of those without metastasis to the regional nodes succumbed during this period. The five year survival rate is 52.4 per cent.

MORTALITY

Of the 167 patients subjected to the Miles operation, only 9 patients succumbed, and the operative mortality was 5.3 per cent. There were also 9 deaths following the fifty-six operations of colostomy and posterior resection, a mortality of 31.5 per cent. The higher mortality is, of course, in keeping with what one would expect in making every effort to see what could be done for the depleted patient harboring the far advanced lesion.

patients died of peritonitis and in another the immediate cause of death was not determined at autopsy. The remaining 4 deaths were the result of intestinal obstruction which was a complication of peritonitis in 2 cases and due to adhesion to the pelvic floor in 2. In 1, an omental band adherent to a seam in the pelvic diaphragm constricted the terminal ileum, while in another the terminal ileum was obstructed by a second loop of small bowel which had become adherent at the same place.

Obstruction low in the small bowel in the patient who is receiving only small quantities of fluids by mouth for the first three days postoperatively can be an insidious process, subtle and slow to manifest itself in a form sufficiently clearcut to warrant reoperation. With progress the picture becomes further clouded and increasingly difficult to interpret. Needless to say, it requires intense fortitude to reoperate in the early post-operative days, but certainly this complication must be emphasized because of the frequency with which it has occurred in this series.

TABLE 2.—Pathologic Studies Made on One Hundred and Sixty-Two Patients with Cancer of the Rectum

Grade	Patients	With Glandular Involvement						Without Glandular Involvement						Living 1946

lated over shorter periods. Of the 167 patients, in only 5 have we been unable to complete the follow-up to date. At this time 85 patients are alive and without evidence of recurrence. This represents a survival rate of 52.4 per cent.

In this group of 167 combined resections, 2 patients succumbed to vascular accident, 1 to a cerebral thrombosis and another to pulmonary embolism. Two

SUMMARY

Down through the years the procedures devised for the surgical removal of cancer of the rectum and rectosigmoid have been many and varied. Repeated efforts have been made to preserve the sphincter mechanism, and repeatedly they have been discarded because of inadequacy. In recent years there has been an energetic revival of this effort.

To strive for the ultimate in postoperative longevity, an extensive surgical removal of the lesion and all gland-bearing tissues in the three zones of lymphatic spread must be accomplished. With proved retrograde metastasis and extension along the levator and muscle sheaths one cannot condone less adequate efforts.

A review of 336 patients with cancer of the rectum and rectosigmoid had been presented. A resectability rate of 75 per cent is recorded, and in 71.7 per cent of those growths resected the Miles operation was found to be applicable. In 167 patients the one stage combined abdominoperineal resection of the rectum was performed with 9 postoperative deaths, a mortality of 5.3 per cent.

In correlating the pathologic changes noted in the resected specimens with the survival of patients operated on, it is demonstrated that prognosis is in direct ratio to the presence and extent of glandular involvement and that glandular involvement is in direct ratio to the grade of malignancy of the lesion. The best yardstick of prognosis is, then, a careful pathologic study of the grade of the lesion and the extent of glandular involvement by metastatic disease.

The mortality rate of 5.3 per cent following the Miles operation is satisfactory so long as the range of resectability is high—emphasizing again that efforts must be directed more forcefully than ever to earlier diagnosis of this readily diagnosed condition.

ABSTRACT OF DISCUSSION

DR. THOMAS E. JONES, Cleveland: Early in the twenties smaller operations were the vogue because of high mortality in major procedures and the struggle to save the sphincter. More recently there has been a tendency to determine the type of operation according to the grade of lesion and its distance within the anus. An earlier study of 103 consecutive cases at Cleveland Clinic pointed to invasion of mesenteric fat as important. Later venous involvement was found in 72 per cent and glandular involvement in 65 per cent, a significant observation when considering anastomosis. Any section, therefore, through veins in the neighborhood will favor early recurrence. In a recent study 80 per cent of the patients had lesions within 12 cm. of the anus, and in this location I perform the abdominoperineal operation. The smallest lesion was 5.2 cm. in diameter and the largest 71.2 cm. in diameter. Of all the cases glands were involved in 59 per cent and the lymph nodes and mesentery fat in 65 per cent. An abdominal colostomy is an inconvenience, but a patient can be happy and content with one. The surgeon must be forceful but sympathetic, encouraging and understanding in instructing the patient. The patient will then become proud and boastful of his special management. The objection to the one stage abdominoperineal resection has been the mortality. This objection has been removed since the mortality has dropped from 25 to 5 per cent. In spite of the shortage of hospital beds and the necessity of substituting typewritten instruction for preoperative hospital care, I have been gratified to note no effect on the mortality. Lowered mortality has been due to improvements in preoperative treatment and rehabilitation and in anesthesia and to advances in chemotherapy, although I have never used intestinal chemotherapy in preparation for operation on the colon or rectum. Close observation is necessary in early recognition of complications. Elimination of infection has contributed much to the good results. Of 137 consecutive cases without a mortality, in only 3 was there any infection of the abdominal wound. Intestinal obstruction, either mechanical or due to chemical, traumatic or bacterial peritonitis, caused over half the deaths, and requires painstaking postoperative care to lower mortality. In 13 cases of mild obstruction only one enterostomy was performed. Without the early use of the Miller-Abbott tube many of these cases would have gone on to obstruction, which used to cause over half the mortalities.

DR. LELAND S. MCKITTRICK, Boston: There are persons who have little or no incentive to live. To them, life with a colostomy may not be worth while. But most persons have a family; they love life, and they do have a real incentive to live. A colostomy is not too big a price for them to pay for those privileges. Your objective is to do the best cancer operation of which you know. If you do your best in any cancer which is below, at or just above the peritoneal floor you will do, if you can, the combined abdominoperineal operation which has been favored by Dr. Rankin and Dr. Jones. We, too, have patients in the hospital five to seven days before operation. I am sure that our patients would miss something if their preparation were done at home. They come to us as strangers. Those five to seven days give us an opportunity to come to know each patient and his problems, and the patient comes to know us. We never discuss the colostomy until the night before the operation. Then we sit down and have a careful and thorough talk of the whole problem. They know that we are doing what we can to help them. Patients understand their problem better, and the acceptance of a colostomy under these circumstances is not too difficult for the patients. When you or I have done a colostomy on a patient, it is our obligation to see the patient through the period of rehabilitation, not only

in the immediate postoperative period but from time to time during the years to come. This has two objectives: It is our obligation to that patient, and also it is our obligation to future patients, because only by seeing these patients, understanding them, talking with them, knowing them, can we have the conviction that we must have if we are to be able to sit down and honestly tell patients that the best chance of cure of their disease means the loss of their rectum; that means a permanent colostomy, and a colostomy is completely compatible with a useful and happy life.

DR. FRANK H. LAHEY, Boston: I do not want to join forces with every effort to overcome all compromises to a radical approach to cancer of the rectum. I feel that we have one chance to cure a cancer of the rectum, and that is the first one, and that there will be no opportunity to change one's mind. It is unfortunate that our estimate of colostomy is based largely—and particularly the public's estimate—on knowledge of and experience with the palliative colostomy, about which patients are inevitably vocal, because they suffer so. It is psychologically unfortunate that the persons who have a good working colostomy are secretive about it, generally, and do not boast about it, as would be a good thing if it could be accomplished. I wish to leave this, because the speaker, Dr. Rankin, and the discussers have so ably defended what I believe in, and that is that a trade for the preservation of the sphincter will in ten years be offset by a decrease in the five year nonrecurrence rates. Dr. Swinton in the Clinic has followed 1,800 autopsies with respect to polyps, and in that connection I want to point out two things: One is the avoidable abdominal resections in some of the polyps in which the microscopic diagnosis is carcinoma. We must bear in mind that in 4 per cent of these cases in which autopsies were done there were polyps and in 42 per cent the polyps were multiple. Also, remember that 25 per cent of the patients who have carcinoma have associated polyps, and it is so easy, when we make a diagnosis of carcinoma of the rectum, not to go further and determine at that time whether or not the patients have an additional polyp which could be taken care of at that time or at least recognized and watched. The important thing I want to bring to you is this—and this is dangerous to say—that there is a type of polyp in which the malignancy as reported by the pathologist is entirely within the polyp, does not involve the base, does not spread onto the mucosa, and I know of some of these that are being resected that in our experience probably do not need to be. We have removed twenty-two polyps in which this pathologic report has been given (and I want to be careful to add this) in which there was no spread over the base, no ulceration and the malignancy was limited to the body of the polyp. These have been followed over a series of years, and there have been no recurrences. The polyps with the malignancy within the body of the polyp and not involving the base we believe can be folgerized and watched, and most of these will not require abdominal sequel. I believe that Dr. Rankin and the discussers have really done us a service by imposing limitation of the operation by preservation of the sphincter, which has been so widely publicized. It is unfortunate that it is easy to persuade patients to choose this operation, but they do not know the price that they may pay.

His Father Was a Minister.—Oliver Wendell Holmes was born in Cambridge, Mass., in 1809. He received his medical degree from Harvard in 1836 and began to practice in Boston. Although Holmes never acquired a large practice he was elected one of the physicians to the Massachusetts General Hospital, and in 1847 was appointed professor of anatomy and physiology at Harvard. His most lasting contribution to medicine is his essay on "The Contagiousness of Puerperal Fever," published in 1843, which in the words of William Osler, "probably saved many more lives than any individual gynecologist." Other works contributing to his literary fame are the "Autocrat of the Breakfast Table," and his novels, notable for their psychological insight, of which "Elsie Venner" is probably the best known. As the son of a New England minister, it is not surprising to find Holmes occupied with problems of theology.—Rosen, George, and Caspari-Rosen, Beate: 400 Years of a Doctor's Life, New York, Schuman's, 1947.

ASPIRATION BIOPSY IN DIAGNOSIS OF LESIONS OF VERTEBRAL BODIES

JOSE VALLS, M.D.
CARLOS E. OTTOLENGHI, M.D.
and
FRITZ SCHAJOWICZ, M.D.
Buenos Aires, Argentina

It is the purpose of this paper to point out the technic, indications and end results obtained with aspiration biopsy of the vertebral bodies.

We think that the application of aspiration biopsy in the lesions of the spine is of great interest, because the vertebral bodies cannot be surgically approached in order to diagnose.

Reviewing the literature, we found only one mention of this method of diagnosis, in Robertson and Ball's paper.¹ These authors stated that since 1932 they had applied this method in 15 patients with various diseases of the spine; in 6 of these cases the diagnosis of malign-

Fig. 1.—Apparatus used in aspiration biopsy. (1) A, sharp point employed to fix the instrument. B, exploring needle. C, aspiration needle. (2) Showing device for disconnecting the guide from the needle.

nant tumor could be made. They summarized the clinical reports for 6 patients: a myeloma of the twelfth dorsal vertebra; Pott's disease primarily localized in the eighth dorsal vertebra, with invasion of the neighboring vertebrae; osteomyelitis of the sixth dorsal vertebra; a case of typhoid spondylitis of the third and fourth lumbar vertebrae; metastases in the sixth cervical vertebra and a process of infectious nature of the fourth and fifth lumbar vertebrae. The authors stated that the procedure is blind and that therefore it is difficult to control exactly the location of the needle. In their paper they did not describe their technic.

To introduce a needle into a vertebral body is a procedure of some risk when the technic is not exact to the detail.

We wish to convey some considerations to justify our opinion that not all the vertebral segments are suitable for puncture.

PARTS OF SPINE SUITABLE FOR PUNCTURE

Cervical Part of Spine.—The anterior arch of the atlas, the body of the axis and the third cervical vertebra are hardly accessible to palpation. Since they are deeply placed in connection with the organs of the neck, it is advisable to find them by the pharyngeal route. The fourth, fifth, sixth and seventh cervical vertebrae are accessible laterally. We will explain the technic later. This portion of the spine is highly accessible to palpation.

Dorsal Part of the Spine.—The bodies of the dorsal vertebrae are in intimate contact with the parietal pleuras, with the descending aorta and accompanying vein, the esophagus, the thoracic duct, etc. It is easy to understand that in an attempt to reach a dorsal vertebral body with a needle, in the superior part, the large arterial and venous trunks could be injured. Our experiences in cadavers causes us to advise against vertebral puncture above the ninth dorsal vertebra.

Lumbar Part of Spine.—The three last dorsal vertebrae and the lumbar vertebrae are highly accessible to aspiration puncture. The pillars of the diaphragm and the insertions of the ileopsoas contribute to form a muscular layer that isolates the lateral part of the vertebral bodies from the neighboring organs. The aorta is placed over the anterior part and slightly left of the vertebral bodies, the inferior vena cava over the anterior right part of the same bodies, advancing a little more laterally than the aorta. The distance from the skin to the mentioned vessels varies between 9 and 10 cm.

The kidneys, placed in the lateral regions, are connected with the spine from the eleventh dorsal to the third lumbar vertebra. It should be pointed out that in accordance with our measurements the distance from the surface of the skin to the renal pedicle varies between 8 and 9 cm.

TECHNIC

We shall describe the instruments and the technic of aspiration biopsy. We must distinguish the puncture of the bodies of the three last dorsal vertebrae and of the lumbar vertebrae from the puncture of the four last cervical vertebrae.

Tenth, Eleventh and Twelfth Dorsal Vertebrae and Lumbar Spine.—Instruments: We employ two needles: one thin and long, the exploring needle, which is used as a stilet, and the other thicker and shorter with which the aspiration is performed, and a guide of direction (fig. 1). The exploring needle must be 18 cm. in length and with a diameter of 1 mm., with the characteristics of the needles commonly used in lumbar punctures, though longer (fig. 1). The second needle is the one which we usually employ for aspiration biopsy, but this needle is marked on its external face. These marks begin at 6 cm. from the sharp point and show the penetration in divisions of 1 cm. up to the tenth centimeter. To give the needle an exact direction we employ a guide that is formed by a metallic ruler divided in centimeters; over this ruler slide a sharp point which is employed to fix the instrument on the middle line. At one of the ends the guide ruler has a channel 2.5 cm. in length, placed at an angle of 125 degrees. The needle will go through this channel when aspirating. A simple device allows us to disconnect the guide from the needle when this is placed in a correct position. Figure 1 shows the device and the needles placed in the guide.

Technic: The patient is placed on an x-ray table, lying on his face. The roentgenographic examination is absolutely necessary to determine the position of the needle accurately. An anesthetic wheal on the middle line over the spinous process is made with a solution of 0.5 per cent procaine hydrochloride.

Address of the invited foreign guest read before the Section on Orthopedic Surgery at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

1. Robertson, R. C., and Ball, R. P.: Destructive Spine Lesions: Diagnosis by Needle Biopsy, *J. Bone & Joint Surg.* 17:749-758 (July) 1935.

The puncture must take place 6.5 cm. from the midline, preferably to the right side to avoid the inferior vena cava. According to our studies in several sections made at different levels of the spine, the distance of 6.5 cm. from the midline can be considered constant, since in all the cases it has been demonstrated that it is the most suitable spot for the introduction of the needle. When the spot where the needle is going to be introduced is chosen, a superficial and deep infiltration of the

Fig. 2.—Showing guide in place.

same anesthetic solution is made, and then with the sharp end of a tenotome a preliminary puncture of the skin is made in order to avoid introduction of the skin into the needle.

The guide is placed (fig. 2); the channel which is on the other end will give the exact angle, that is 35 degrees. It is important to insist on this point. Figure 3 shows the guide in place with the needle touching the vertebral body. According to our investigations, insertion of the needle at this angle 6 or 7 cm. deep, circumventing the transverse process, brings it to the vertebral body. With an inclination of 45 degrees to 50 degrees, the needle might enter the intervertebral foramen; as the course of the needle is oblique, it must go in diagonally and reach the lateral part of the dura without any risk of damaging the cord. Only the roots can be punctured, and in this case the patient complains of radicular pain, which indicates that the direction must be correct. If the angle of penetration is decreased when the needle is about 7 cm. beneath the skin, it does not strike bone. If it went deeper, the renal pedicle could be touched; it is 8 or 9 cm. from the skin at the level of the second lumbar vertebra.

The aorta is almost impossible to reach because it is very anterior, approximately 9 to 10 cm. from the skin; since the inferior vena cava extends somewhat to the right of the vertebral body, its puncture, though remote, may be possible if the needle goes in more than 9 cm. and in a direction closely perpendicular to the skin; this is a gross error of technic.

The thin needle is placed inside the other, and the exploring puncture is performed with the thin needle, which, being longer, extends beyond the thicker needle (fig. 1). The latter at the beginning only penetrates into the posterior soft parts. The puncture is performed without mandrel. The needle is attached to a syringe to allow the aspiration as the needle is going in. Whether it has reached some vessel or the rachidian channel must be determined. When the guide needle reaches the vertebral body, the mandrel is introduced to make sure that nothing has clogged the needle. It is at this moment that antero-posterior and lateral roentgenograms are taken. When it has been determined by the roentgenograms that the needle is placed in the suitable spot, the thick needle is pushed in; when it touches the vertebral body, the thinner needle and the guide are withdrawn. If the vertebral body is soft, one sees how the needle penetrates it, and the aspiration is performed and the vacuum maintained while the point of the needle is moved backward and forward. If on reaching the body there is some

difficulty in penetrating it, one may, without losing contact with the body, slide the needle 1 or 2 cm. and may find a softer zone. If one acts like this and maintains contact with the bone obstacle, there is no danger of injuring any important organ. Before performing the aspiration it is convenient to pass the mandrel through the thick needle to avoid the clogging of this needle.

We think that the insertion of the thin guide needle is the best precautionary measure. Any organ reached by the thin needle would not suffer any important damage. In case the rachidian channel or a vessel is reached, the issuing of blood or cephalorachidian fluid would show this and would permit change of direction of the puncture. This did not happen in any of our cases.

Alberto Gutierrez² in describing in detail the technic of the anesthesia of the lumbar sympathetic according to Kappis, pointed out the possibility of puncturing the aorta or the inferior vena cava; this fact has not brought any inconvenience. His opinion was shared by other authors.

Once the aspiration is performed, the needle is attached to the syringe and is withdrawn. The material obtained is emptied into a test tube with saline solution to be examined afterward.

The puncture may also be performed without the guide and the aforementioned technic, but in this case experience is required to give the needle the exact direction. Since the technic which we have described is not difficult, we think it an advisable course to follow.

Cervical Part of Spine.—As we have said, the biopsy is performed in the last four cervical vertebrae

Fig. 3.—Showing guide in place with the needle touching the vertebral body in lumbar part of spine.

for diagnosis. The bodies of the first three vertebrae are easily found by the pharyngeal path. Moreover, it has been observed that the last four cervical vertebrae are the vertebrae of this region most frequently hurt.

Since the vertebral bodies are smaller than in the dorsal and lumbar regions, we do not think it suitable

2. Gutierrez, A.: Anestesia esplénica; algunas consideraciones sobre ella: contribución personal, *Semana méd.* 2: 1-17, 1922.

to reach them posteriorly. We therefore recommend the puncture laterally.

The outjutting course must be followed as a guide. As the arteries and nerves of the neck are covered by this muscle in its superior part, one never must go through it, but remain on the posterior border.

When the muscle goes downward and forward toward its inferior insertion, the artery and nerve that go down vertically extend past the posterior border of the muscle in the base of the neck; for this reason we advise that the puncture not be made in front of the vertical descending from the posterior border of the mastoid.

The cervical and brachial plexus may be reached by the needle without any inconvenience other than the pain which the patient feels.

The esophagus may only be reached if the needle goes in very deeply.

The vessel that may be reached more easily during the puncture is the vertebral artery, which, after coming out from the subclavian artery, goes upward toward the hole in the base of the transverse apophysis of

Fig. 4.—Showing positions of needles in aspiration in cervical portion of spine. Needle 1 is inserted in the right position.

the sixth cervical vertebra; as the artery goes along the channel that is in the remaining apophyses of the cervical vertebrae and these apophyses have a disproportionate size in relation to the bodies—the needle when directed toward the body may easily reach the vertebral artery; nevertheless, we cannot verify this accident in any of our cases.

Lambret, Razemon and Decoulx, who in 1939 published a monograph on surgery of the sympathetic and its infiltrations,³ made an analytic study, very precise, of the different technics to reach the neurovegetative system. On describing the different ways in which the stellar ganglion can be infiltrated, they mentioned the organs that may be reached by the needle in its course, and they added that the injury of the vessels that “a priori” may appear of great importance is not so in practice, and in general the vessels remain free of danger. According to these authors, this is shown in their numerous personal cases and the great number of infiltrations of the stellar ganglion that have been performed without complications.

3. Lambret, O.; Razemon, P., and Decoulx, P.: *Technique de la chirurgie du sympathique et de ses infiltrations*, Paris, Gaston Doin & Cie, 1939.

The penetration of the needle into the rachidian channel is impossible because the intervertebral foramina have an oblique direction from the inside to the outside and from the back to the front, and as the needle goes in a direction from outside to inside and from back to front, it is easy to understand that to go into the channel is nearly impossible, as can be seen in roentgenograms of the section going through the fifth cervical vertebra. To enter into the channel the needle must go from the front to the back, going through the sternomastoid muscle; the muscle, as has been said, must always be in front of the needle when the puncture is correct.

Technic: Once the lesion is located, the patient is placed in lateral decubitus. The posterior border of the sternomastoid is palpated and the vertical is drawn from the posterior border of the mastoid; a dermic welt is made with procaine hydrochloride. A superficial incision is made with a tenotome and the puncture is performed with the same needle. The first needle must be attached to a syringe to aspirate (puncture of a vessel). The direction of the needle must be from outside to inside and slightly from the back to the front, about 3.5 cm. It must reach the bone. If blood is aspirated, the needle must be carried a little more to the front to escape the obstacle offered by the transverse processes (fig. 4).

When the vertebral bodies are reached, anteroposterior and lateral roentgenograms are taken; if the place of the needle is accurate, the thick needle is pushed forward, the thin needle is withdrawn and aspiration is performed in the usual manner.

We applied the puncture to diagnosis in 86 cases of lesions of the spinal column. The localizations were as follows:

	Cases
Cervical part of spine.....	9
Dorsal part of spine.....	18
Lumbar part of spine.....	46
Not known.....	13
	86

The types of lesion in 68 of these 86 cases are as follows:

	Cases
Metastatic carcinoma.....	32
Myeloma.....	9
Angioma.....	1
Tuberculosis.....	12
Unspecific inflammatory processes.....	8
Echinococcosis.....	2
Osteoporosis and others.....	4
	68

In order to appreciate the results, we made the following classifications:

Positive: Cases in which it was possible to determine accurately the nature of the lesion (59 cases).

Satisfactory: Cases in which the study of aspirated material permitted establishment of adequate therapy but not of the classification of the lesion (10 cases).

Negative: Cases in which, on account of the lack of material, the diagnosis could not be done (6 cases).

Doubtful: Cases in which the diagnosis could not be made because of lack of information (11 cases).

In several cases the puncture was repeated once or twice without serious accident.

With material aspirated, smears were made and sections performed. The microscopic study of the slides obtained with both methods gave us satisfactory results.

The following cases are reported to demonstrate the value of this method of diagnosis.

REPORT OF CASES

CASE 1.—The disease was metastasis of Malpighi's epithelioma to the third lumbar vertebra. The patient, A. A., aged 48, was admitted to the hospital Aug. 3, 1939.

History.—When he was 19 years old the patient got a syphilitic primary lesion; he had local treatment and was cured after fifteen days. There were no secondary phenomena. Gonorrhea at the age of 20 was cured after a month. When he was 47 years old he had pulmonary congestion followed by a sero-fibrinous pleurisy; a month afterward it turned purulent. He was operated on and a fistula remained that discharged periodically. The illness in question began three months later with pain in the sacrolumbar part of the spine, extending to the right lower limb. The patient was unable to walk and had to remain in bed. He was given intravenous injections of iodine and salicylate, local heat and three injections of mercury and vitamin B. The right lower limb improved; the pain was located in the lumbar vertebrae. There remained a certain degree of paralysis and muscular atrophy of the right lower limb. At the same time the pleural sinus began to discharge.

Dorsal Decubitus.—The patient moved with difficulty. Hypotrophy and hypotonia of the muscles were noted, mainly of the lower limbs. There was scoliosis to the left. Pain was elicited between the third and fourth lumbar vertebrae. Active and passive movements were possible.

Thorax: An operative scar was observed over the last rib on the left. There was a spot from which reddish pus exuded.

The right lung seemed normal except for rude respiration. In the left lung there was solidity in the lower third; vocal

infiltration. After the examination of the gross specimen the surgeon thought it a neoplastic degeneration of the ulcer.

The present illness started with pain in the sacral region extending to the sacroiliac joint and right hip. The pain

Fig. 5.—Roentgenograms showing destructive process involving three-fourths of the body of the third lumbar vertebra.

vibrations were diminished. There was little entrance of air in the base. In the upper two thirds there was some rhonchus and rude respiration, almost blowing. There was aphonic pectoriloquy in the lower third. In the lower limbs there were pronounced hypotonia, paresis and abolition of reflexes. In the sacrum region a cutaneous sore was observed. Roentgenograms (fig. 5) showed a destructive process involving three-fourths of the body of the third lumbar vertebra. Aspiration puncture was performed.

Pathologic Examination (fig. 6): The tissue obtained in the puncture showed abundant neoplastic tissue of the type of Malpighi's epithelioma. The patient died Oct. 22, 1939.

We think that the presentation of this case is highly interesting because the antecedents of the patient were not sufficiently clear to indicate clinically the existence of a process of a neoplastic nature in the spine.

CASE 2.—The disease was metastasis of a gastric carcinoma into the fourth lumbar vertebra. The patient had undergone a gastrotomy four years previously with the diagnosis of ulcer, a diagnosis that was corrected after the vertebral aspiration biopsy. The patient, aged 40, was admitted May 22, 1939.

History.—When he was 36 years old the patient was operated on for gastric ulcer. The pathologic diagnosis of that lesion was chronic ulcer, pronounced chronic gastritis and extensive

Fig. 6.—Photomicrograph of metastasis of Malpighi's epithelioma.

increased in severity and was still worse on walking. He stopped work twenty days before admission and remained in bed four days. There was no fever. At the time of examination he felt pain in the lumbar spine, sacral region and right

Fig. 7.—Showing lateral destructive lesion of the body of the fourth lumbar vertebra, with flattening of the body and preservation of the intervertebral disk.

hip. He walked with slow steps. After the illness began he noticed that the movements of the spine were limited. Examination revealed rigidity of the lumbar portion of the spine, with pain on percussion of the fourth lumbar vertebra.

Roentgenograms (fig. 7) revealed a lateral destructive lesion of the body of the fourth lumbar vertebra with flattening of the body and preservation of the intervertebral disk. On June 30 aspiration biopsy of the fourth lumbar vertebra was done.

Pathologic Report.—In the specimens examined it was clearly seen that the tumor mass was formed by epitheliomatous cells, cubic and polygonal ones, with evident tendency to mucoid secretion and formation of *Ringszellen* (fig. 8).

Fig. 8.—Photomicrograph of tumor mass showing cubic and polygonal epitheliomatous cells, with tendency toward formation of *Ringszellen*.

Diagnosis.—The diagnosis was metastasis of epithelioma with mucoid secretion of gastrointestinal origin (stomach). According to this report the histologic slides were checked again and our diagnosis was confirmed.

Treatment and Course.—July 18, 1939 a plaster jacket was applied, with traction on both legs. Roentgenograms of the left hip taken July 9 revealed further metastasis. On September 5, at the family's request, the patient was sent back home, where he died on arrival.

Not only is this case highly demonstrative of the certainty of the aspiration biopsy, but also as a result of the aspiration biopsy a diagnosis suspected by the surgeon when the gastrectomy was performed was confirmed.

CASE 3.—The disease was metastasis of Malpighi's epithelioma in a patient with pulmonary tuberculosis. The patient, C. C., aged 58, was admitted to the hospital on Feb. 14, 1940.

History.—In 1893 he had some hemoptysis. Treatment was rendered and he recovered.

Present Illness.—At the beginning of July 1939, he noted hemoptysis. Twenty days later, while lying in bed, he felt a sudden pain in the right scapula that became severer on palpation; then pain gradually extended to the arm and forearm.

The patient referred the pain to the bones of these parts. Pain grew with time and became severer during the night. At admission pain was continuous. He also felt pain in the right side up to the anterior region of the neck. At the same time he began to feel anorexia. He had lost 10 pounds (4.5 Kg.) since the beginning of the illness.

The analyses of sputum performed were positive for the Koch bacillus. At the beginning in the roentgenograms there were atelectatic shadows in the base of the left lung and in both

lungs there were calcified nodules. The pain in the arm persisted; therefore roentgenograms of the dorsolumbar portion of the spine were taken.

At the level of the sixth cervical vertebra a large area of destruction of the body and the transverse processes was found. It was immediately thought that it was a neoplastic metastasis. The possibility of a primary carcinoma of the stomach was investigated to allow confirmation. As the patient presented dysuria for two months a urologist was consulted who found a hypertrophic prostate. He did not find signs of neoplasm of the prostate. According to the process, one thought of a neoplasm of the lung. The patient had vomited without effort. The liquid vomit preceded by nausea had disappeared.

Physical Examination.—The patient was in fair condition. In bed he lay with his head motionless, bending it to the right side. Contracture of the right sternomastoid muscle, bending of the head to the right side, antalgic rigidity, pain and contracture of the cervical spine and pain stretching to the left shoulder and arm were noted. Presternal and parasternal swelling was observed on the level of the fifth, sixth and seventh cervical vertebrae.

A roentgenogram of the lungs on Feb. 17, 1940 revealed diffuse infiltration of irregular borders, veiled, that occupied all the base of the left lung. There were some cavities in the vertex of the same side. A roentgenogram of the cervical part of the spine revealed a destructive process of the body of the sixth cervical vertebra, flattening of this body and reduction of the height of the disks. Aspiration biopsy of the sixth cervical vertebra was done.

Pathologic Report (Frotis).—Small cellular groups were observed, formed by two or more polyhedral cells of epithelial aspects with large and clear nuclei, showing atypia, abnormalities and great nucleoli.

Conclusion: Carcinomatous cords and alveoli of Malpighi cell type were observed with definitely atypical cells and numerous abnormalities.

Fig. 9.—Showing destructive lesion of the twelfth dorsal vertebra and first lumbar vertebra with preservation of the intervertebral disk.

Diagnosis: The diagnosis was metastasis of Malpighi's epithelioma.

Guinea Pig Inoculation.—A guinea pig inoculation was negative.

Treatment and Course.—The cervical portion of the spine was immobilized and roentgen therapy was given. The patient died in September.

CASE 4.—The disease was myeloma of the fourth cervical vertebra. V. M., aged 61, was admitted to the hospital Aug. 17, 1940.

History.—One year previously limitation of motion of the cervical portion of the spine, especially in the movement of flexoextension, was noted. After twenty days the limitation was greater, and as he was leaving the physician's house he fainted and fell, knocking his left shoulder against the floor.

Fig. 10.—Showing chronic inflammatory tissue with zones of necrosis and tubercles formed by epithelial cells, lymphocytes and giant cells of Langhans type.

Immediately the pain increased at the level of the nape and ability to move the cervical part of the spine disappeared completely. He remained in bed some days but he could not sleep. After three months, the pain diminished and the ability to move the cervical portion of the spine reappeared. Four months before admission pain recurred suddenly, showing the same signs. For two months before admission the cervical part of the spine had been bending, and when he entered the hospital his chin touched the sternum in permanent posture.

Condition at Time of Admission.—The cervical portion of the spine was in hyperflexion, the jaw being in contact with the sternum. There was slight cervical scoliosis to the right with contracture of the posterior muscles of the neck. Pain was felt on percussion on the spinous process. Movements were absent. There was a destructive process of the fourth cervical vertebra; subluxation in flexion was almost total.

On August 30 aspiration biopsy of the fourth cervical vertebra was done.

Pathologic Report.—Smear: Numerous round cells with the aspect of plasma cells were observed.

Conclusion: It was concluded that there was a tumor mass uniformly constituted of round cells of the plasma cell type, many of them atypical or with two nuclei.

Diagnosis: The diagnosis was plasmocytic myeloma.

CASE 5.—The disease was tuberculous spondylitis of multiple foci, seeming a metastatic tumor. The patient, H. R. C., aged 32, stated that when he was 20 years old he had a suppurative process of the sternum. There were large scars. This process was of an acute beginning, with fever and the forma-

tion of an abscess. It was cured in two months; at the same time he presented pain and rigidity of the nape. In November 1939 pain of little intensity appeared in the lumbar region; pain increased when he coughed and sneezed. A month later pain increased. A physician diagnosed appendicitis, and he was operated on. On leaving the bed he was well for a week, but the pain appeared after that time. The pain radiated to the right hip, thigh and knee. Rest mitigated the symptoms. Roentgen therapy and heat were employed without results.

A new physician took a roentgenogram of the lumbar part of the spine, and according to it a plaster jacket was made. Pain was immediately relieved. The temperature went as high as 38 C. (100.4 F.). The general aspect was good. When he was examined for the first time he had the plaster jacket on, so that satisfactory examination of his spine could not be made.

A roentgenogram (fig. 9) showed a destructive lesion of the sixth and twelfth dorsal vertebrae and of the first lumbar vertebra. The vertebral bodies were uniformly flattened; the intervertebral disks were normal. These lesions led one to think that they were of a malignant nature. The Wassermann reaction was positive. The sedimentation rate was 60 in the first hour and 120 in the second hour.

Aspiration biopsy of the first lumbar vertebra showed chronic inflammatory tissue, with zones of necrosis and tubercles that were formed by epithelial cells, lymphocytes and some giant cells of the Langhans type (fig. 10).

Guinea pig inoculation was negative. It must be pointed out that the material injected was very scarce.

The diagnosis was tuberculosis.

The patient was seen several times later. He goes on resting in bed and in the plaster jacket. The general status is excellent and there is no pain.

We think that this case is of great interest because it was difficult to confirm a clinical diagnosis. At the beginning we thought more of a lesion of spondylitis, remembering the process that appeared when the patient was 20 years old, and we also thought of the possibility of a tumor.

Fig. 11.—Destructive lesion of inferior third of body of second lumbar vertebra.

The aspiration biopsy allowed us to discard this diagnosis, because the tissue obtained was of purely inflammatory nature and with the characteristics of the lesions of tuberculosis. At any rate, it was an atypical case in which the biopsy was highly useful. The slides of that case were observed by Professor Ewing, who confirmed our diagnosis.

CASE 6.—J. C., aged 18, was admitted to the hospital on July 16, 1941.

Illness at Time of Admission.—The onset of his illness was three months previously, with pain in the left side of the lumbar region. In erect position or in bed he did not feel any pain. His general condition on admission was good. It was possible to observe, on examination, a slight protrusion of the second lumbar vertebra and mild dorsal scoliosis. He complained of pain at the second and third lumbar vertebrae. There was full range of motion of the spine.

Roentgenograms.—Roentgenograms (fig. 11) revealed at the level of the second lumbar vertebra a destructive lesion with formation of osteophytes in its upper part. There was slight sclerosis of the second vertebral body; the intervertebral disk was slightly narrowed. A lateral view (fig. 11) showed a destructive lesion of the inferior third of the vertebral body with neoformation at the anterior margin.

Aspiration Biopsy.—Microscopic examination revealed striated muscular fibers and necrotic tissue with lymphocytes and cells of the fibroblastic or epithelioid type.

The diagnosis was tuberculosis.

Bacteriologic examinations were negative. The guinea pig inoculation was positive for tuberculosis.

HUMAN BRUCELLOSIS

Its Specific Treatment with a Combination of Streptomycin and Sulfadiazine

WESLEY W. SPINK, M.D.

WENDELL H. HALL, M.D.

JAMES M. SHAFFER, M.D.

and

ABRAHAM I. BRAUDE, M.D.

Although brucellosis was one of the first infectious diseases for which Koch's postulates were established, specific therapy for this disease has remained in an unsatisfactory state. In 1936, Carpenter and Boak¹ reviewed the therapeutic methods which had been used up to that time for human brucellosis and concluded that "a successful method for the treatment of brucellosis still awaits development." Fortunately, this timely survey of therapy by these authors appeared just before sulfanilamide was introduced for the treatment of bacterial infections. In the decade that has elapsed since sulfanilamide became available, other sulfonamide compounds and the antibiotics have appeared. This report embraces a series of experimental and clinical investigations on the specific therapy of brucellosis that have been carried out during the past ten years in the laboratories and clinics of the University of Minnesota Hospitals, and the results indicate that there is a more satisfactory approach to the treatment of human brucellosis.

EXPERIMENTAL EVALUATION OF THE SULFONAMIDE DRUGS AND ANTIBIOTICS AS ANTI-BRUCELLA AGENTS

The fundamental requisite of successful therapy for human brucellosis is that treatment should not only control the infection but that *Brucella* should be eradicated from the tissues.

This therapeutic principle has been the basis for seeking out a more satisfactory form of specific therapy in this clinic. It became apparent during the course of the present investigations that an experimental method was needed which would permit the rapid screening of the sulfonamide compounds and the antibiotics as potential therapeutic agents for human brucellosis. Furthermore, the evaluation of any given drug should be based not only on the degree of protection against infection afforded by the agent, but also on the ability of the drug to eliminate *Brucella* from the tissues and body fluids. While it was known that small animals such as mice and guinea pigs could be successfully infected with *Brucella* and the protective action of drugs could be evaluated by treating these animals, such procedures are time consuming and relatively expensive. Since Goodpasture and Anderson² had shown that the tissues of chick embryos could be infected with *Brucella*, it appeared that a similar technic could be applied to testing the antibrucella properties of the sulfonamide compounds and the antibiotics. After many attempts and the utilization of several thousand fertilized chicken eggs, a simple and rapid method for obtaining reproducible data has been worked out. While this work was in progress, Jones, Metzger, Schatz and Waksman³ reported that chick embryos infected with *Brucella* could be protected with streptomycin. Because the results with infected chick embryos parallel the results obtained in human patients, the experimental method will be summarized briefly. A more detailed description will be given elsewhere.⁴

Fertilized eggs from the same source were used. Seven day chick embryos were inoculated via the yolk sac with a twenty-four hour broth culture of *Brucella abortus* recently isolated from a human patient. Uniformly lethal infections were established in the infected embryos, so that 50 per cent were dead within six days after infection and 100 per cent within nine days. Viable *Brucella* organisms were consistently cultured from the livers of these infected embryos. Twenty-four to seventy-two hours after *Brucella* cells had been inoculated into the yolk sac, the therapeutic agent to be evaluated was injected into the sac. In this manner, sulfanilamide, sulfapyridine, sulfathiazole, sulfadiazine and sulfamerazine were evaluated. Particular attention was given to sulfadiazine, since this drug was being used in the treatment of human patients. Although all the sulfonamide compounds tested prolonged the survival rate of infected embryos as compared with non-treated infected controls, the treatment failed to eradicate viable *Brucella* organisms from the tissues of the majority of the embryos. Since penicillin afforded little or no protection, more extensive observations were made with streptomycin. The latter yielded results similar to those obtained with sulfadiazine; that is, treatment of the embryos prolonged life, but the majority of sacrificed embryos harbored viable *Brucella* organisms. Of considerable significance was the fact that when sulfadiazine and streptomycin were introduced simultaneously into the yolk sacs of infected

cated from the tissues. This therapeutic principle has been the basis for seeking out a more satisfactory form of specific therapy in this clinic. It became apparent during the course of the present investigations that an experimental method was needed which would permit the rapid screening of the sulfonamide compounds and the antibiotics as potential therapeutic agents for human brucellosis. Furthermore, the evaluation of any given drug should be based not only on the degree of protection against infection afforded by the agent, but also on the ability of the drug to eliminate *Brucella* from the tissues and body fluids. While it was known that small animals such as mice and guinea pigs could be successfully infected with *Brucella* and the protective action of drugs could be evaluated by treating these animals, such procedures are time consuming and relatively expensive. embryos, not only was the survival rate greater but *Brucella* organisms were absent from the cultures of tissues in the majority of the embryos. It has been demonstrated repeatedly that the combination of sulfadiazine and streptomycin has a much more effective antibruella action than either drug alone. The results of a typical experiment are illustrated in chart 1. The important feature in this particular experiment is that the livers of only 13 per cent of the embryos contained viable *Brucella* organisms when the combination was employed in treatment, whereas *Brucella* organisms were recovered from 77 per cent treated with streptomycin and 92 per cent treated with sodium sulfadiazine. While the foregoing results have dealt with infections due to *Br. abortus*, the combination of sulfadiazine and streptomycin has been just as effective for infections due to *Brucella suis* and *Brucella melitensis*.

SULFONAMIDE COMPOUNDS AND STREPTOMYCIN

Thirty-five patients with active brucellosis have been studied and observed by us, and we have directed therapy. Twenty of the patients received one of the sulfonamide compounds, particularly sulfadiazine; 7 were treated with streptomycin, while 9 had a combination of sulfadiazine and streptomycin administered to them. It is to be emphasized that these cases of sporadic brucellosis were proved bacteriologically by isolation of *Brucella* organisms from the tissues or body fluids. Agglutinins for *Brucella* were demonstrated in the serums of all the patients in titers ranging from 1 to 80 up to 1 to 5,120. A larger number of patients have been treated in this clinic with these agents, but in order to provide for a critical clinical evaluation only the bacteriologically proved cases were selected for analysis in this report. *Br. abortus* was isolated from 33 of the patients and *Br. melitensis* from 2. As is pointed out in tables 1, 2 and 3, many of the patients had been ill for several months and severe complications were present such as subacute bacterial endocarditis, spondylitis and encephalitis.

Sulfonamide Therapy.—Clinical reports which have appeared would indicate that patients having acute brucellosis with bacteremia have made satisfactory response coincident with the administration of one of the sulfonamide compounds.⁵ On the other hand, less encouraging results have also been presented.⁶ In view of the lack of agreement concerning the value of the sulfonamide compounds in human brucellosis, the results of therapy in a significant group of patients have been evaluated in this clinic.

The pertinent clinical data and a summary of the therapy are presented in table 1. In the treatment of these patients varying dosage schedules were used, but the aim of treatment was to administer a total of 6 Gm. of a sulfonamide compound a day for approximately three weeks. Four of the patients received sulfanilamide, one sulfamerazine and 15 sulfadiazine. Six of the patients appeared to have recovered completely after the administration of a sulfonamide drug (cases 1, 3,

5, 6, 10 and 15). It is of interest that 2 of these patients had severe spondylitis demonstrable roentgenologically. Recovery of these patients was undoubtedly in part due to rest in bed and immobilization of the spine. Two of the patients (cases 4 and 17) were improved after therapy, but complete recovery occurred only after a considerable length of time. Sulfanilamide did not alter the course of 1 patient (case 2) who had subacute bacterial endocarditis.

Seven of the patients (cases 7, 8, 12, 13, 16, 18 and 19) had positive cultures for *Brucella* after the cessation of therapy. In several instances, there was temporary improvement in the condition of the patients but clinical and bacteriologic relapses occurred after treatment. There is every indication that sulfonamide therapy did not eradicate *Brucella* from the tissues in well over one third of the patients. Furthermore, recovery in some of the remaining patients might well have been independent of sulfonamide therapy and more directly associated with bed rest. Following the observations of others,⁷ we carried out splenectomy in 1 patient (case 13) in an attempt to eliminate a possible persistent focus of infection. In this particular case

Chart 1.—Illustrating comparative results of sulfadiazine and streptomycin, and a combination of the two, in protecting chick embryos against infection with smooth culture of *Br. abortus* (infecting dose: 364 organisms.) Note eradication of *Brucella* from tissues by combination of sulfadiazine and streptomycin as judged by cultures of livers of infected and treated embryos.

such a procedure was without benefit. Multiple cultures of the spleen remained sterile for *Brucella*. This and other studies on the pathogenesis of brucellosis have convinced us that splenectomy in brucellosis, except in extremely rare cases, is just as illogical as removing the spleen from patients with chronic relapsing malaria.

Streptomycin Therapy.—One of the remarkable properties of streptomycin is that the *in vitro* growth of all three species of *Brucella* is inhibited by concentrations of the antibiotic which can be readily attained in the blood of human subjects.⁸ Live, Sperling and Stubbs⁹ concluded that streptomycin protected experimentally infected guinea pigs, but in a later report Kelly and Henley¹⁰ found that streptomycin possessed

little value as a therapeutic agent for mice and guinea pigs infected with *Br. suis*. Several investigators have reported disappointing results following the treatment of human beings with streptomycin.¹¹ However, Finch¹² was encouraged over the results obtained in 6 patients, although 3 of the 6 patients had demonstrable *Brucella* bacteremia after therapy had been concluded. It is of interest that Hewlett and Ernstene¹³ reported a case in which *Br. abortus* was cultured from bile

Seven patients, all with infections due to *Br. abortus*, were treated with streptomycin.¹⁴ Data pertaining to these patients are presented in table 2. The streptomycin was administered intramuscularly in divided doses totaling 2 to 5 Gm. daily. In three instances (cases 2, 5 and 7), therapy with streptomycin had to be discontinued because of toxic reactions to the drug such as fever and dermatitis. In no instance did complete recovery follow the administration of strepto-

TABLE 1.—Summary of Sulfonamide Therapy in Twenty Patients with Active Brucellosis

Case No.	Age	Sex	Duration of Disease	Complications	Bacteriology	Treatment	Results
1	64	M	5 mo.	Cervical spondylitis	<i>Br. abortus</i> from blood once	Sulfanilamide—69 Gm. in 13 days; Thomas collar	Complete recovery; no relapse in 6 yr.
2	36	M	5 mo.	Subacute bacterial endocarditis	<i>Br. abortus</i> from blood 8 times	Sulfanilamide for 40 days prior to hospitalization	No improvement; died after 8 mo. of illness; <i>Br. abortus</i> from vegetations on mitral valve
3	25	M	8 mo.	Lumbar spondylitis	<i>Br. abortus</i> from blood once	Sulfanilamide—84 Gm. in 16 days; body cast and brace	Complete recovery; no relapse in 6 yr.
4	36	M	4 mo.	None	<i>Br. abortus</i> from blood once	Sulfadiazine—109 Gm. in 25 days	Marked improvement; residual weakness; no relapse in 2½ yr.
5	12	M	3 mo.	None	<i>Br. abortus</i> from blood twice	Sulfadiazine—13.5 Gm. in 7 days	Complete recovery; no relapse in 2½ yr.
6	42	F	3 mo.	Thyrototoxicosis	<i>Br. abortus</i> from blood once	Sulfanilamide—46 Gm. in 10 days; iodine; thyroidectomy	Complete recovery; no relapse in 7 yr.
7	36	M	4 mo.	Purulent sinusitis	<i>Br. abortus</i> from blood once	Sulfadiazine—109 Gm. in 19 days; drainage of sinus	Temporary improvement; clinical and bacteriologic relapse
8	40	M	4 mo.	None	<i>Br. abortus</i> from blood 3 times	Sulfadiazine—134 Gm. in 21 days; 81 Gm. in 14 days	Temporary improvement; clinical relapse; recovery after second course of therapy; no relapse in 3 yr.
9	6	M	5 mo.	Conjunctivitis from chickenpox at time brucellosis recognized	<i>Br. abortus</i> from blood once	Sulfadiazine—14 Gm. in 17 days	Improvement; dermatitis from sulfadiazine; given artificial fever therapy
10	65	F	7 mo.	None	<i>Br. abortus</i> from blood once	Sulfadiazine—72 Gm. in 15 days	Complete recovery; no relapse in 2 yr.
11	67	F	8 mo.	None	<i>Br. abortus</i> from blood once	Sulfadiazine—41 Gm. in 10 days	Slight improvement; abacteremic
12	44	M	3½ mo.	None	<i>Br. abortus</i> from blood twice	Sulfadiazine—94.5 Gm. in 17 days	Improvement; bacteriologic relapse
13	28	F	4½ mo.	None	<i>Br. abortus</i> from blood 3 times	Sulfadiazine—134 Gm. in 23 days	Marked improvement; bacteriologic relapse; splenectomy without benefit
14	35	F	14 mo.	Blurring of vision	<i>Br. abortus</i> from blood once	Sulfadiazine—127 Gm. in 21 days	No improvement; abacteremic
15	23	M	1 wk.	None	<i>Br. abortus</i> from blood once	Sulfadiazine—57 Gm. in 11 days	Complete recovery; into Army
16	66	F	6 mo.	None	<i>Br. abortus</i> from blood twice	Sulfadiazine—35.5 Gm. in 18 days; 67 Gm. in 15 days	Improvement; bacteriologic relapse after first course; <i>Br. abortus</i> from cerebrospinal fluid after second course
17	28	M	4 yr.	None	<i>Br. abortus</i> from blood twice	Sulfamerazine—42 Gm. in 11 days	Improvement; drug fever and dermatitis from sulfamerazine; residual weakness
18	41	M	3 mo.	None	<i>Br. abortus</i> from blood 3 times	Sulfadiazine—126 Gm. in 21 days; 69 Gm. in 12 days	Temporary improvement after each course; clinical and bacteriologic relapse after each course
19	32	M	5 days	None	<i>Br. melitensis</i> from blood twice	Sulfadiazine—109 Gm. in 21 days; 45 Gm. in 7 days	Clinical and bacteriologic relapse after first course; clinical relapse after second course
20	41	F	2 wk.	None	<i>Br. melitensis</i> from blood once	Sulfadiazine—125 Gm. in 21 days; 42 Gm. in 7 days	? Clinical relapse after first course; complete recovery after second course

obtained by duodenal drainage. After treatment with streptomycin, cultures of bile remained sterile and the condition of the patient was considerably improved.

mycin. In case 21, *Brucella* organisms were isolated from the blood during therapy, although the in vitro growth of this strain was inhibited by 2 micrograms per cubic centimeter of streptomycin. The clinical course of this patient is depicted in chart 2. It is of interest that in this case dermal sensitivity was induced by streptomycin and by phenobarbital. Patient 23 had had chronic brucellosis for twenty-seven months. When he was admitted to the hospital he had signs and symptoms consistent with the diagnosis of subacute

14. In several instances, streptomycin was supplied by Dr. Chester S. Keefer, Chairman of the Committee on Chemotherapeutic and Other Agents of the National Research Council.

bacterial endocarditis due to *Br. abortus* with evidence of involvement of the aortic valve. He was given a total of 118 Gm. of streptomycin over a period of thirty-one days. Coincident with this there was a decline in temperature and clinical improve-

by 50,000 micrograms per cubic centimeter of streptomycin. This resistant culture produced two types of colonies on agar plates, a large and a small colony. The growth of both colonies, especially the small colonies, was stimulated in several types of mediums

TABLE 2.—Summary of Results with Streptomycin in Seven Patients Having Brucellosis

Case No.	Age	Sex	Duration of Disease	Complications	Bacteriology	Treatment	Results
18*	41	M	3 mo.	None	<i>Br. abortus</i> from blood 3 times	21 Gm. in 4 days	Clinical and bacteriologic relapse
21	11	F	6 mo.	None	<i>Br. abortus</i> from blood 5 times	18.25 Gm. in 9 days	Drug fever from streptomycin; bacteremia during and after treatment; gradual improvement
22	24	M	1 mo.	None	<i>Br. abortus</i> from blood 4 times	32 Gm. in 8 days	No improvement; abacteremic after treatment
23	33	M	2½ yr.	Subacute bacterial endocarditis	<i>Br. abortus</i> from blood 7 times, bone marrow once, urine once	118 Gm. in 31 days	Improvement; <i>Br. abortus</i> from blood highly resistant to streptomycin after treatment; abacteremic after large doses of sulfadiazine; died congestive heart failure, vegetations aortic valve sterile at autopsy
24	46	M	20 mo.	None	<i>Br. abortus</i> from blood	22 Gm. in 6 days	Improvement; drug fever and dermatitis from streptomycin; abacteremic
25	35	M	2 yr.	Encephalitis	<i>Br. abortus</i> from cerebrospinal twice	32.7 Gm. in 10 days (0.1 Gm. intrathecally twice)	Improvement; cerebrospinal fluid sterile after streptomycin
26	47	M	1 mo.	None	<i>Br. abortus</i> from blood twice	26.8 Gm. in 10 days	Improvement; drug fever and dermatitis from streptomycin; also given sulfadiazine; clinical and bacteriologic relapse

TABLE 3.—Summary of Nine Patients Having Brucellosis and Treated Simultaneously with Streptomycin and Sulfadiazine

Case No.	Age	Sex	Duration of Disease	Complications	Bacteriology	Treatment	Results
27	45	M	9 mo.	Subacute bacterial endocarditis	<i>Br. abortus</i> from blood 4 times	Streptomycin—52 Gm. in 14 days; sulfadiazine—129 Gm. in 22 days	Vertigo; complete recovery; abacteremic and working 9 mo. after treatment
28	28	F	9 mo.	Radiculoneuritis left arm	<i>Br. abortus</i> from blood once; bone marrow once	Streptomycin—57 Gm. in 15 days; sulfadiazine—120 Gm. in 22 days	Complete recovery; no relapse 9 mo. after treatment
29	28	M	2 mo.	Mesenteric adenitis with disabling right lower quadrant pain	<i>Br. abortus</i> from blood once	Streptomycin—22 Gm. in 8 days; sulfadiazine—115 Gm. in 20 days	Complete recovery; no relapse 4 mo. after treatment
30	32	M	9 mo.	Spondylitis	<i>Br. abortus</i> from blood once	Streptomycin—14.5 Gm. in 8 days; sulfadiazine—142 Gm. in 24 days	Complete recovery; coincident with treatment marked abatement of back pain
31	57	M	3 wk.	None	<i>Br. abortus</i> from blood once	Streptomycin—14 Gm. in 8 days; sulfadiazine—124 Gm. in 21 days	Complete recovery
32	25	M	2 mo.	None	<i>Br. abortus</i> from blood twice	Streptomycin—14 Gm. in 7 days; sulfadiazine—76 Gm. in 12 days	Apparent complete recovery; spleen remained palpable
33	31	F	2 mo.	Rheumatic heart—mitral stenosis	<i>Br. abortus</i> from blood once	Streptomycin—14 Gm. in 7 days; sulfadiazine—102 Gm. in 21 days	Apparent complete recovery; chill, fever on 20th day of therapy
34	21	M	1 mo.	None	<i>Br. abortus</i> from blood 7 times	Course 1: streptomycin—18 Gm. in 9 days; sulfadiazine—68 Gm. in 9 days; course 2: Streptomycin—24 Gm. in 12 days; sulfadiazine—94 Gm. in 18 days	Recurrent bacteremia 3 days after 1st course; apparent complete recovery after 2d course
35	33	M	1 mo.	Femoral vein phlebotrombosis; pulmonary emboli; pleural effusion; pulmonary edema; amebiasis	<i>Br. abortus</i> from blood twice	Course 1: streptomycin—71 Gm. in 25 days; sulfadiazine—204 Gm. in 27 days; penicillin—10,100,000 units in 25 days; course 2: streptomycin—13.8 Gm. in 5 days; sulfadiazine—28 Gm. in 5 days; penicillin—6,650,000 units in 19 days	No clinical response following emetine; blood sterile after 6 Gm. streptomycin but clinical condition much worse; fever, tender liver and spleen, repeated pulmonary infarction; slow recovery on combined chemotherapy plus oxygen, feeding by gastric tube, parenteral fluids, anticoagulants, thoracenteses; residual pleural fibrosis and pneumonitis

ment. However, toward the end of treatment with streptomycin, and after therapy had been discontinued, *Brucella* organisms were isolated from the blood. As reported elsewhere,⁸ the original culture isolated from this patient's blood was sensitive in vitro to 1 microgram per cubic centimeter of streptomycin, whereas the growth of the culture obtained from his blood after the discontinuance of therapy was not completely inhibited

by the addition of sublethal concentrations of streptomycin. The streptomycin-resistant cultures isolated from this patient proved to be rather sensitive to sulfadiazine, and for this reason he was treated with large oral doses of sulfadiazine. Coincidentally with therapy he became afebrile and blood cultures remained sterile. But clinical and electrocardiographic evidence was presented which indicated the development of severe myo-

carditis, and he died suddenly from myocardial failure. Postmortem examination revealed a bicuspid aortic valve with a superimposed vegetation. Cultures of this vegetation, heart's blood, liver, spleen, lymph nodes and other tissues did not yield *Brucella*. The myocardium showed evidence of a diffuse and severe

Chart 2.—Demonstrating failure of therapy with streptomycin in L., a girl aged 11 years, with brucellosis due to *Br. abortus* (duration of illness, six months). Treatment discontinued because of drug fever and dermatitis.

inflammatory reaction. It appeared that *Brucella* had been eradicated from the tissues and blood of this patient after intensive treatment with streptomycin and sulfadiazine. As a result of the observations made in this patient in February 1947 and the investigations already under way with the chick embryo technic, it was decided to abandon the use of streptomycin alone in the treatment of human brucellosis in favor of combined treatment with streptomycin and sulfadiazine. The predominating feature in case 25 was encephalitis with isolation of *Br. abortus* from the cerebrospinal fluid, but not from the blood. Coincidentally with the injection of streptomycin into the subarachnoid space the spinal fluid became sterile.

Combined Sulfadiazine and Streptomycin Therapy.—Nine patients with active brucellosis proved bacteriologically have been treated simultaneously with sulfadiazine and streptomycin. Six of the patients had acute brucellosis, while 3 had the chronic form of the disease. The illness was considered to be chronic in those persons who had had manifestations of the infection for three months or more. The essential clinical information pertaining to these patients is shown in table 3.

It is to be noted that the total doses of the two drugs used varied from patient to patient. While streptomycin was administered intramuscularly every six hours, the total daily dose was from 2 to 4 Gm. given over a period of seven to twenty-five days. With a few exceptions, the doses of sulfadiazine given orally were 4 Gm. initially and then 1 Gm. every four hours for three weeks. As a precaution against renal complications from sulfadiazine, the daily fluid balance was observed, and alkalization of the urine was induced by administering a total of 16 Gm. of sodium bicarbonate every twenty-four hours in divided doses. There were no complications due to the sulfonamide therapy. Streptomycin in a dose of 4 Gm. daily for fourteen days

caused a disturbing and persistent vertigo in 1 patient (case 27), but aside from this 1 case no toxic effects were observed.

The results of treatment in this group of cases are highly encouraging. One patient (case 27) had been disabled for nine months. Initial studies revealed evidence of subacute bacterial endocarditis with involvement of the aortic valve. The clinical course of this patient is presented in chart 3. *Br. abortus* was recovered from the blood four times prior to treatment. Although the titer of agglutinins in his serum for *Brucella* was 1 to 2,560, intradermal tests remained negative with those *Brucella* antigens, which usually produce a delayed type of reaction. The failure of patients with *Brucella* endocarditis to respond locally to *Brucella* antigen is a feature of this disease that has been commented on elsewhere.¹⁵ The patient was given streptomycin with a total daily dose of 4 Gm., and he received 52 Gm. in fourteen days. A total of 129 Gm. of sulfadiazine was administered in twenty-two days. It is significant that after treatment and recovery, intradermal tests with *Brucella* antigens gave a delayed type of reaction. Except for a residual vertigo, this patient has remained well for nine months following treatment. Numerous cultures of venous blood have been sterile. Three months after the completion of treatment a biopsy of his liver was carried out and histologic examination did not reveal the presence of granulomatous lesions. In other investigations carried out in this clinic, these lesions have been observed in every case of proved brucellosis studied in this manner.¹⁶ The aortic murmur decreased considerably in intensity. There is every indication that this patient has recovered from a heretofore fatal complication of brucellosis.

Another instance of chronic and disabling brucellosis was exhibited in case 28. This farm wife was confined to bed with fever, chills and radiculoneuritis of the left

Chart 3.—Illustrating the clinical course of A. M., a man aged 45, having subacute bacterial endocarditis due to *Br. abortus* (duration of illness, nine months), and successfully treated with a combination of sulfadiazine and streptomycin.

arm. Prompt recovery followed the combined type of treatment with no relapse of her illness during the nine months after therapy. Case 29 was of particular

clinical interest in that this patient had had recurrent attacks of fever, swelling of the peripheral lymph nodes and disabling pain in the right lower quadrant of the abdomen. The latter manifestation was interpreted as being due to mesenteric adenitis. He recovered promptly and completely after treatment, with no evidence of active disease four months later. Patient 30 had been in a state of ill health for several months. He had chills, fever, weakness and severe pain over the lumbar region for one month. The pain in the back was so great that repeated doses of morphine were necessary. Although roentgenologic studies failed to establish the diagnosis it was the general opinion that he had spondylitis due to *Br. abortus*. After the completion of combined therapy the pain abated entirely, and he has had no recurrence of his illness after a lapse of four months. Case 33 demonstrated an instance of bacteremia due to *Br. abortus* in a patient who had mitral stenosis following an attack of rheumatic fever several years previously. The danger of a superimposed *Brucella* infection on the mitral valve was averted by combined therapy. The treatment of patient 33 has been of some aid in determining how long sulfonamide therapy should be continued after the cessation of treatment with streptomycin. He received 2 Gm. of streptomycin daily for nine days and a total of 58 Gm. of sulfadiazine over the same length of time. He appeared to respond to this short course of combined treatment, but he relapsed clinically and bacteriologically three days after treatment had been discontinued. A more prolonged course of treatment, especially with sulfadiazine, resulted in prompt recovery without a subsequent relapse.

Case 35 represents an unusually severe series of complications occurring in a patient with acute brucellosis and demonstrable bacteremia. On entrance to the hospital he had chills and fever without definite localizing signs. He had had amebic dysentery in the past, and when studied on the present occasion both the cysts and vegetative forms of *Endamoeba histolytica* were found in his stools. The diagnosis of amebic hepatitis was entertained but adequate therapy with emetine was without effect. After the establishment of the diagnosis of brucellosis he was given combined therapy, but his course was interrupted by the occurrence of multiple pulmonary emboli. The source of these emboli was believed to be a phlebothrombosis in his leg. Pulmonary edema developed after one episode, and then pleural effusion and pulmonary suppuration. For these reasons, an intensive program of chemotherapy was instituted, which included the use of penicillin, heparin and "dicumarol." He improved slowly and there has been no recurrence of brucellosis.

In summary, the combined use of streptomycin and sulfadiazine in the therapy of patients with either acute or chronic brucellosis has yielded more satisfactory results than has been previously obtained in the University of Minnesota Hospitals. The results are particularly encouraging since the treatment was effective in complications of brucellosis such as subacute bacterial endocarditis and spondylitis.

COMMENT

While the combination of streptomycin and sulfadiazine is an effective form of therapy for human brucellosis, the optimum dosage schedule has not been

determined with certainty. Furthermore, it is possible that another sulfonamide compound or a combination of sulfonamide compounds might be more satisfactory. As a result of the foregoing investigations, a total daily dose of 2 Gm. of streptomycin given for seven days has been suggested, because such an amount appears to give the desired results and toxic reactions are less likely to occur than if larger doses are used or if streptomycin is administered over a longer period of time. It is apparent that it is necessary to administer sulfadiazine for at least two and preferably three weeks. In order to obtain significant and reliable data in a relatively short period of time, an attempt was made to give arbitrary doses of streptomycin and sulfadiazine without too much variation. Pulaski and Amspacher^{11c} gave streptomycin to 17 patients having either acute or chronic brucellosis without benefit, but when streptomycin was combined with sulfadiazine in 2 patients having acute brucellosis there was a prompt response. As a result of this observation they recommended a dose of 0.5 Gm. of streptomycin intramuscularly every six hours and 1 Gm. of sulfadiazine every four hours for at least two weeks.

It is to be emphasized again that the results of combined therapy described in this report are based on the treatment of patients having brucellosis proved bacteriologically. This criterion of diagnosis was essential in dealing with such a variable disease as brucellosis. However, in this clinic other patients having a febrile illness compatible with the clinical features of brucellosis and a high titer of agglutinins for *Brucella* have been successfully treated. It remains to be seen whether the combined therapy will be satisfactory in so-called chronic brucellosis, that is, in patients having a vague type of illness, sterile blood cultures, absent or a low titer of agglutinins and a positive intradermal test with *Brucella* antigen. Thus far, we have been reluctant to give streptomycin and sulfadiazine to this group of patients, primarily because one is too frequently in doubt as to whether active disease is present.

Although combined therapy with streptomycin and sulfadiazine has yielded the most satisfactory results to date in this clinic, the intensive investigations on other antibiotics going on at the present time may bring forth other agents more effective against *Brucella* than streptomycin.

SUMMARY

During the past ten years, specific antibrucella therapy has been investigated at the University of Minnesota Hospitals experimentally and in 35 sporadic cases of human brucellosis proved bacteriologically.

A chick embryo technic being utilized, screening of therapeutic agents has been carried out. The combined administration of sulfadiazine and streptomycin proved to be more effective than either agent alone. A remarkable correlation of therapeutic results in infected chick embryos and human patients has been observed.

Nine patients have been treated with a combination of sulfadiazine and streptomycin, which has yielded more satisfactory results than any other therapy used to date. It is recommended for the present that streptomycin be administered intramuscularly in doses of 0.5 Gm. every six hours for seven days. Therapy with sulfadiazine should be initiated simultaneously with an oral dose of 4 Gm. and then 1 Gm. every four hours for at least two and preferably three weeks.

MARGARINE AND THE GROWTH OF CHILDREN

HARRY LEICHENGER, M.D.

GEORGE EISENBERG, M.D.

and

ANTON J. CARLSON, Ph.D., M.D.

Chicago

This study was undertaken to determine whether there is any nutritional difference, as shown by increases in height and weight in significantly large groups of children, when the source of supplementary table fat in their diets is vegetable (margarine) rather than animal (butter).

For a number of years there has been some controversy among nutritionists and other workers in the field of fat nutrition regarding the relative merits of animal and vegetable fats in the human diet. A great deal of experimentation has been carried out, the laboratory rat being used, in the main, as the experimental animal.

Little experimental work has been done in fat nutrition, however, among human subjects. For that reason, the present study was decided on. To insure valid results, examinations of the 267 children (white) included in this study were made for a period of two years.

As early as 1925 Holmes,¹ in studies carried out on human subjects, found that margarine was from 93 to 97 per cent digestible. Bunker,² in 1927, stated:

Beef fat excreted in the milk of the cow is no different in its origin from beef fat which is retained within the animal, although the chemistry of butter fat and oil differ somewhat. Each is a suitable food. The vegetable oils, also, such as olive oil, palm oil, coconut oil, peanut oil, cottonseed oil, and others are all suitable foodstuffs. The digestibility of the various animal and vegetable fats is high.

Some years later Carlson³ stated:

All the scientific data on the digestibility, flavor and color of the dietary fats show clearly that there is no significant difference in digestibility between animal and vegetable fats and that the acceptability of those fats in regard to color and flavor is a matter of past conditioning of the individual and of no other significance in nutrition.

Boutwell⁴ and others, after experimental studies on rats, concluded:

1. With lactose as the sole carbohydrate . . . rats showed superior growth when fed butter or lard as compared to corn oil, coconut oil, cottonseed oil, soybean oil, peanut oil, olive oil and hydrogenated cottonseed oil. 2. With a mixture of carbohydrates composed of sucrose, starch, dextrose, dextrin and lactose in the diet, the average growth response of the animals fed vegetable oils was equal to that of the animals fed butter and lard. The growth rate on this ration was more rapid than when all the carbohydrate was present as lactose. 3. Properly fortified oleomargarine fats gave growth equal to butter fat over a period of six weeks when the above mixture of carbohydrates was incorporated in the rations.

From the Department of Pediatrics, University of Illinois College of Medicine.

Aided by a grant from the National Association of Margarine Manufacturers. Terms of the grant provided that findings from the study could be published, regardless of results.

Deuel,⁵ on the other hand, found no difference in the growth of weanling rats at any time over a twelve week period whether they were fed mineralized skimmed milk powder, vitamin supplements and butter, or corn, cottonseed, peanut or soybean oils, or margarine. The extent of growth was confirmed at three and six weeks by roentgen determinations of length of the tibia. Also, the efficiencies of conversion of these various fats to body tissue were identical. These experiments refute the idea that butter fat possesses certain fatty acids not present in other fats, which are essential to growth.

The Council on Foods and Nutrition of the American Medical Association⁶ stated:

It is therefore possible to conclude that at present there is no scientific evidence to show that the use of fortified margarine in an average adult diet would lead to nutritional difficulties. A similar statement is probably justified in the case of growing children, but preliminary reports from animal experiments indicate that more work is necessary before any specific conclusions can be made.

Graves⁷ stated:

When pure, all fats are equally available for the energy needs of the body . . . the shortening powers and keeping qualities of [both butter and margarine] are about the same and they are equally assimilable.

Again, Bloor⁸ pointed out:

Very little need be said about the relative nutritional value of fats and hence of availability and distribution for the reason that most of the ordinary food fats of both plant and animal origin consist mainly of the same few fatty acids—oleic, palmitic and stearic—in varying proportions, and it is to be expected that they would not differ much in digestibility or in metabolic usefulness.

Recently Deuel⁹ reaffirmed the fact that vitamin-fortified margarine has a nutritional value substantially equivalent to that of butter. This belief is supported by the conclusions of an entirely unprejudiced group, the Committee on Public Health Relations of the New York Academy of Medicine, which recommended in its report of Feb. 1, 1943, that wide publicity, both lay and professional, be given to the fact that margarine fortified with vitamin A is nutritionally equal to butter. A similar conclusion was reached by the Food and Nutrition Board of the National Research Council in its Reprint and Circular Series No. 118, released in August 1943.

Cowgill¹⁰ concluded:

Edible fats, the melting points of which are not too high to prevent liquefaction in the alimentary tract, are digested and absorbed to about the same degree. Such differences as have been found are of no practical nutritional significance. . . . Natural fats differ with respect to their content of the essential unsaturated fatty acids but the amounts needed by the organism are so small that these are probably of no practical nutritional significance. Natural fats have not been found to differ appreciably in their effect on the body's needs for other dietary essentials. . . . In a diet otherwise nutritionally satisfactory, a vegetable fat such as that contained in

a margarine can serve adequately in place of butter fat for growth and reproduction, as shown by experiments with eight and more successive generations of rats.

Boer and colleagues¹¹ recently reported on the presence of vaccenic acid in summer butter. They stated that vaccenic acid has growth-promoting properties in rats. Euler and associates,¹² however, reported inability to demonstrate any growth-promoting factor peculiar to butter. Moreover, the same authors¹³ in later studies "to characterize the physiological influence on the rat's organism of different fats . . . compared the growth, the fertility and the longevity of rats, which were reared on a fat nutrition, consisting either of butter or of margarine (fat mixture MW)." They concluded "that the nutritional and physiological value of the slightly varying fat mixtures, which we employed under the designation of MW and which correspond to the margarines manufactured in Sweden during the period from October 1943 to November 1946, is in no way inferior to the value of butter."

Deuel and associates,¹⁴ meanwhile, found vegetable fats and margarine equal to or better than butter in supporting augmented growth in two series of tests with rats, based on administration of growth hormone from the anterior lobe of the pituitary body.

PLAN OF STUDY

Two groups of children were included in the study, which covered a period of two years. One group received only margarine as the table fat in the diet. It was used on bread and vegetables, as well as in the making of pastry and in frying. Fortified margarine was supplied by a number of the various companies now manufacturing the product and was the same as that sold to the public. The margarine used was all derived from vegetable fats, and contained no fat from animal sources. The second group of children used only butter for the same purposes.

The margarine group lived in an institution housing 130 children ranging in age from 3 to 16 years. The children were half-orphans, for the most part from broken homes. They attended the neighborhood schools and returned to the institution for lunch. Samplings also indicated that the children were served margarine on their occasional visits to families outside the institution.

The butter group was in another institution some 10 miles (16 kilometers) away. It included 125 children ranging in age from 6 to 17 years, who were mostly orphans.

The diet in each institution was carefully supervised by trained dietitians and so regulated that 25 to 30 per cent of the total calories were supplied by fat. The margarine constituted approximately 65 to 70 per cent of the total fat calories.

All of the children in both groups were weighed and measured each month under medical supervision. A careful check was made from time to time to be sure that weights and measurements were accurately deter-

mined. Routine red blood cell counts and hemoglobin determinations were made on each child after the study was started and again one year later. Specialists in pediatrics supervised the medical care of all the children. A record was kept of the character and duration of all illnesses contracted by the children.

RESULTS

At the close of the study more than 200 records were available for analysis in the margarine group. Because of the turnover in the institution, the period of study was not uniform and ranged from about a month to a maximum of twenty-four months. In the butter group there were about 150 records available, ranging up to twenty-four months' observation time on weight, height, red blood count, hemoglobin and illnesses.

It was found that those children who stayed a very short time had extreme irregularities in weight gains. Since it would serve no useful purpose and only increase the margin of error in the computations, all those records of children who were studied less than six months were discarded. About 40 in each group were so eliminated, leaving 160 records in the margarine group and 107 in the butter group.

Blood Studies.—There were 65 children in the margarine group and 85 in the butter group from whose records differences in erythrocyte count and hemoglobin could be computed. At the beginning of the study there was an average red cell count of 4,284,000 in the margarine group, the lowest being 3,710,000 and the highest 4,870,000. One year later the average was 4,198,000, the low 3,440,000 and the high 5,560,000. Comparable figures for the butter group were as follows: At the beginning, the average red blood cell count was 4,629,000; low, 3,940,000; high, 5,640,000; one year later, the average was 4,640,000; low, 3,920,000, and high, 5,560,000.

In the margarine group the average hemoglobin was 13.7 Gm. per hundred cubic centimeters, with a low of 11.3 and a high of 16.6. One year later the figures were 13.4, 10.5 and 18.6, respectively. For the butter group, at the beginning of the study the hemoglobin figures were: average, 15.4 Gm.; low, 13.8, and high, 17.9. One year later the findings were: average, 15.3; low, 12.4, and high, 17.5.

All these figures are within normal limits in our clinical experience. Moreover, according to Osgood and Baker,¹⁵ there is an average of 12 Gm. of hemoglobin, ranging from 10 to 14 Gm., in the blood of normal children from 4 to 13 years of age. Griffith and Mitchell¹⁶ stated that the red blood cell count remains at about 4,500,000 to 5,000,000 throughout childhood. Hence it would appear that the blood cell counts in both institutions were in line with counts found in similar groups of children. Furthermore, any variations which occurred were well within the usual errors in making hemoglobin and red blood cell determinations.

Height and Weight.—All the records contained data on weight in pounds and ounces and height in inches. Gains in weight and height are partly a function of time, so a further adjustment had to be made to facilitate valid comparison. The basis of exactly one year was used for standardization. The period of the greatest majority of the cases was over a year. Since this means that the majority had to be reduced in value to be

standardized, chance errors tend to be reduced as well.

An analysis of the total cases in each group is shown in tables 1 and 2. Average annual weight and height gains for boys and girls are shown. For additional comparison, the average gains from standard height-weight tables are included under the column headed "Standard."

Since changes in weight and height are also a function of age, only groups of like age are compared.

The standard error is appended to each value in the margarine group, and comparable value in the butter group. For a test of statistical significance at the 5 per cent level, the difference between two comparable entries in the margarine and standard columns must be greater than twice the standard error. For instance, on the first line in table 1, under "Boys," in the column headed "Margarine," the average yearly gain in weight was 6.7 pounds (3,039 Gm.) with a standard error of 0.6 pound (272.2 Gm.). Twice 0.6 is 1.2, which added to 6.7 gives 7.9 pounds (3,583.4 Gm.). The average gain in the standard column is 7.2 pounds (3,265.9 Gm.), well within the range of the standard error, and the difference is, therefore, not statistically significant.

TABLE 1.—Average Yearly Gain in Weight (in Pounds) for Children Observed at Least Six Months

Age, Years	Boys			Girls		
	Margarine	Butter	Standard	Margarine	Butter	Standard
All (2-15)	6.7 ± 0.6		7.2	7.1 ± 0.6		6.9
All (6-17)		7.0	7.9		5.9	7.1
6-13.....	7.2 ± 0.7	8.8 ± 0.9	7.5	8.0 ± 0.7	7.2 ± 1.0	8.0

6-9.....	5.3 ± 0.5	7.1 ± 2.2	6.5	7.5 ± 0.5	8.3 ± 1.7	6.2
10-13.....	12.3 ± 1.7	9.4 ± 1.0	9.5	10.6 ± 1.3	7.1 ± 1.1	9.7
14-17.....		6.6	8.7		5.4	5.2

TABLE 2.—Average Yearly Gain in Height (in Inches) for Children Observed at Least Six Months

Age, Years	Boys			Girls		
	Margarine	Butter	Standard	Margarine	Butter	Standard
All (2-15)	2.2 ± 0.1		2.3	2.1 ± 0.1		2.2
All (6-17)		1.5	1.8		1.0	1.7
6-13.....	2.0 ± 0.1	2.1 ± 0.1	2.1	2.0 ± 0.1	1.2 ± 0.1	2.1
2-5.....	2.5 ± 0.1		3.0	2.3 ± 0.1		2.7
6-9.....	1.9 ± 0.1	1.9 ± 0.2	2.0	2.1 ± 0.1	1.5 ± 0.3	2.2
10-13.....	2.2 ± 0.2	2.2 ± 0.2	2.2	2.0 ± 0.1	1.2 ± 0.1	2.0
14-17.....		0.7	1.2		0.4	1.0

For a test of significance between a margarine and butter value the formula

$$\sigma_{\bar{x}_1 - \bar{x}_2} = \sqrt{\sigma_{\bar{x}_1}^2 + \sigma_{\bar{x}_2}^2}$$

is used. In only 3 cases does it seem necessary to perform this test. This is in table 1, under Boys, ages 6-13 and ages 6-9, and table 3, under Boys, 6-9 years of age. In none of these cases was the difference found significant.

In both table 1 and table 2 all average gains in the margarine group were at least as great (including the standard error) as the gain in either the butter group or a standard group, with two exceptions. These exceptions were in the 2 to 5 year age groups. This is due to the fact that the average age in this particular group in the margarine study was greater than the midvalue of the group. In fact, there were only 1 boy and 1 girl 2 years old included in the study.

It is believed that the adjustment of all the values to an annual basis is accurate. However, to eliminate doubt as to the validity of the method, comparisons were made using only those subjects who were observed for the maximum time. There were 51 children in the

margarine group who were studied the maximum time of twenty-four months. In the butter group there were 53 under observation for the maximum twenty-four months.

Again the values were reduced to an annual average gain, going far to reduce chance errors, since all values were practically halved. Tables 3 and 4 exhibit the data.

TABLE 3.—Average Yearly Gain in Weight (in Pounds) in Children Observed Twenty-Four Months

Age, Years	Boys			Girls		
	Margarine	Butter	Standard	Margarine	Butter	Standard
All (2-15)	6.7 ± 0.9		7.2	8.2 ± 1.0		6.9
All (6-17)		8.1	7.9		6.3	7.1
6-13.....	7.4 ± 1.2	8.7 ± 1.2	7.5	9.5 ± 1.1	8.3 ± 1.2	6.0
2-5.....	4.0 ± 0.5		5.2	4.0 ± 0.4		4.6
6-9.....	5.1 ± 0.6	6.7 ± 2.3	5.5	6.3 ± 1.1		6.2
10-13.....	12.2 ± 2.4	9.4 ± 1.3	9.5	11.0 ± 1.7	8.3 ± 1.2	9.7
14-17.....		7.0	8.7		6.7	5.2

In only one case, the 2-5 year age group in the boys, in table 4, is the comparison unfavorable. In all other combinations margarine shows up as at least as efficient a source of fat for growth as butter in the normal diet.

COMMENT

It is evident from the tables that growth of the group fed margarine, as determined by increases in height and weight, was comparable to that of the children fed butter and to standard height and weight values for the same age group.

Furthermore, it was noted that in the margarine group there was no increase in the amount of illness. Illnesses in general had been on the decline in the margarine group for the last four or five years, and this decrease in the incidence of illness continued during the period of the study. This compares with conditions present in the community for the last five years.

It was interesting to observe how the children accepted margarine. When it first made its appearance on the table—in its white form—and the study was explained to the children, the younger children promptly accepted it. The childrer in the older age group did not take to it too kindly. Very shortly thereafter, however, a shipment of colored margarine came in. This was cut up into the usual pats and all the children then ate it readily and liberally. Thereafter it was always served cut in pats and colored.

At no time during the period of the study was it considered that vitamin A played any definite role in the results of the study. The reason, of course, is that

TABLE 4.—Average Yearly Gain in Height (in Inches) in Children Observed Twenty-Four Months

Age, Years	Boys			Girls		
	Margarine	Butter	Standard	Margarine	Butter	Standard
All (2-15)	2.2 ± 0.2		2.3	2.2 ± 0.2		2.2
All (6-17)		1.6	1.8		0.9	1.7

2-5.....	2.5 ± 0.1		3.0	2.5 ± 0.1		2.7
6-9.....	2.0 ± 0.4	2.0 ± 0.1	2.0	2.4 ± 0.2		2.2
10-13.....	2.3 ± 0.3	2.2 ± 0.2	2.2	2.0 ± 0.2	1.2 ± 0.2	2.0
14-17.....		0.7	1.2		0.1	1.0

all the margarine used contained 15,000 units of vitamin A per pound—which is equal to or greater than the amount present in average butter.

Blood studies showed that there were no significant differences between the margarine or butter groups.

The children in the margarine group experienced a high degree of good health during the study, and in comparing their health to that of the butter group it appears to have been much better.

When infirmary records are compared it is readily seen that the margarine group fared much better than the butter group. We are not making any claims that the margarine group were healthier simply because their diet contained margarine. Other variables are more likely to account for their better health.

At no time during the course of the study did either institution experience any type of epidemic, and no doubt this may in part be due to the fact that both institutions practiced accepted preventive measures on all their children.

CONCLUSIONS

Growing children experience normal growth in height and weight when their diets contain only fortified margarine as table fat, as shown by comparison with children fed on similar diets with butter as the source of table fat and by comparison with standard height and weight tables.

Whether the greater part of the fat of the diet is derived from vegetable or animal sources has no effect on growth and health as shown by changes in height and weight and health records of children observed over a two year period.

During a two year period the health of 267 children was uniformly good so far as serious illness is concerned, regardless of whether margarine or butter was the source of the greater part of the fat in the diet.

If there is a growth factor present in butter which is not present in margarine, there is no evidence in the present study that such a factor plays any important part in the growth of children as determined by increases in height and weight.

Margarine is a good source of table fat in growing children, as determined by a two year study. Children readily accept margarine as a table spread when it is colored and served in pats.

Special Article

PALLIATIVE TREATMENT OF THE PATIENT WITH ADVANCED CANCER

ERNEST M. DALAND, M.D.
Boston

This article is the eighth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

Many thousands of patients with cancer are being cured each year with the resources already at the command of physicians, but there are just as many who are not cured. The very existence of each of these uncured patients drives home the fact that possibly some physician did too little or saw the patient too late or possibly the patient had a type of cancer in which there was only a remote chance of cure, whatever or whenever it was done. Every death from cancer is indicative of failure somewhere along the line; failure to teach patients to come early for advice, failure of the physician to act quickly and thoroughly or failure of the members of the medical profession to find the cause of and a sure cure for all cancers. Since this is true the attitude of the physician who is dealing with a patient with advanced cancer must be one of humility. It behooves him to do all he can to help the patient through his final days.

RELATION OF PHYSICIAN AND PATIENT

This article deals with the palliative treatment of the patient with advanced cancer. It is assumed that the cancer is considered incurable by present day methods and that any treatment administered is given to make the remaining days more tolerable. Not infrequently treatment intended to be palliative may be curative. The condition of no patient is positively hopeless as long as he is alive.

What does this patient know about his condition? Does he know that he has cancer or has had cancer? What policy should be adopted in general in dealing with the cancer patient? Which physician is right, the one who never tells or the one who usually tells the patient that he has cancer?

Dr. Richard Cabot¹ in his day created a sensation about the advisability of telling patients the truth. Dr. Cabot visited the Pondville Hospital, one of Massachusetts' two cancer hospitals. He was particularly interested in the attitudes shown by the patients and the physicians. He heard 2 patients ask if they had cancer and noted the replies made. Later in the day he was asked whether the physicians were upholding his teachings in regard to telling patients the truth, and his answer was, "Certainly, I never said that you had to tell them the whole truth."

My associates and I are accustomed to seeing hundreds of cancer patients in the Pondville Hospital and

¹From the Pondville Hospital (Massachusetts Department of Public Health), Walpole, Mass., and the Tumor Clinic of the Massachusetts General Hospital, Boston.
1. Cabot, R.: The Meaning of Right and Wrong, New York, The Macmillan Company, 1933, p. 313.

clinics each month. Every patient knows that it is a cancer hospital and that he would not be there unless there was a suggestion of cancer. If the patient asks the nature of his ailment he is told, but the seriousness of the lesion and the prognosis is not revealed necessarily. Still, in face of these conditions, Dr. Richard Cabot in a public meeting stated that the morale of the patients in the Pondville Hospital surpassed that of any he had ever seen in his wards in a general hospital.

I recall the patient who stated that she knew she had cancer but asked me not to tell her husband; an hour later the husband told me that I must do everything possible to keep his wife from learning that she had the disease. I believe the time has come to call a spade a spade and not to follow the course of the physician who recently referred a cancer patient with the statement that, "I told her she had something bad, but I did not use 'the word.'" Sometimes the patients are amused at the physician's clumsy attempts to avoid the issue.

It has been my experience that the patient with treatable cancer is more willing to have treatment, is a better patient during treatment and is more apt to be faithful in his follow-up visits if he knows something about the diagnosis of his case and the program to be followed.

The patient with advanced cancer who has been let in on the secret early, possibly before he had radiation or surgical therapy, is doubtless wise enough to know that his persistent or recurrent ailment is the same disease not responding to treatment. He will not ask many questions, for he knows he is failing and will not have to be told.

I do not advocate going out of one's way to deliberately tell a man that death is around the corner. I did that once with a Catholic clergyman who had failed to do well after several operations, as I thought he might wish to prepare for death. He was amazed at the statement and was unwilling to believe it. The patient with cancer never gives up hope and will fight as long as his physician stands by.

HOSPITALIZATION

The problem may arise as to whether a given patient should be treated at home or in a hospital. There are many factors to be considered, such as the degree of pain, the need for dressings, the number of persons in the home and the facilities for home nursing care, and an individual decision must be made. The patient would like to be at home or near home so that he might see his friends and relatives.

Ideally, there should be beds for a limited number of patients with advanced cancer in every community general hospital. If all hospitals cooperated in this program, the burden would not be great on any one institution. The intern and the resident as part of their training should be taught to care for these patients. Many hospitals refuse to admit patients with advanced cancer or to let them stay once they have been declared incurable. As a result the intern and the resident never see the late course of the disease and do not profit by autopsy observations. How can these physicians care for cancer patients in their homes if they have not been taught? How can they be expected to show interest in patients with incurable cancer when the attitude of their teachers has been to get rid of them

as soon as possible? Where are private duty nurses in the home or visiting nurses going to learn the care of the cancer patient?

The patient who is suffering from an incurable cancer is one of the physicians' greatest trials; he knows that the disease is incurable but he must show no less interest in the patient because of that. He must listen to his symptoms and try to relieve them. He must not avoid making calls or be hasty in his attentions. At the Pondville Hospital patients with advanced disease are treated in rooms on the same wards as those with less advanced radiation or operative cases. They receive the same number of visits and the same degree of attention as their more fortunate neighbors. It is less difficult for the visiting physician or resident to see the good and the bad in turn than it would be if those with advanced cancers were isolated in one group. Rogers² has stated, "There is no case of advanced cancer in which 'there is nothing to be done.' Its successful care demands from the doctor a high degree of skill, cheerfulness, understanding and attention to detail."

MEDICAMENTS

If all methods of treatment have failed, the physician knows that death is inevitable, but it may be a long time coming. He may be forced to prescribe drugs that are addicting, and they should be used with care so that therapy may remain effective. The use of mild drugs and hypnotics for the relief of pain can postpone the use of narcotics.

It is erroneous to think that the cancer patient is entitled to all the opiates he wants. He should receive as much as he needs and no more. Any excess will not only cause addiction but increase the patient's discomfort from nausea, vomiting, constipation, itching and euphoria. If the physician is cautious it will not be necessary to increase the strength of the medicament faster than the disease progresses.³ On the other hand, it should be emphasized that if neurosurgical relief measures are used the dosage of the drugs should be reduced quickly to avoid addiction.

A distinction should be drawn between drugs which aid sleep and those that relieve pain. Sometimes a mild pain remover will allow the patient to gain the required sleep. Again, a mild hypnotic may allow sleep without a pain-relieving drug. The ill patient is more conscious of his pain at night and will require more drugs at night. The patient who goes without drugs by day will not need morphine at night but will get along on acetylsalicylic acid. If he receives this medicament by day he may need codeine at night; if codeine relieves the pain during the day he may require morphine at night.

As far as possible the patient should not be allowed to decide when he shall take medicaments or which drug he is to use. When pain is mild or intermittent, he may be the best judge. He should never be given a box of narcotic tablets to take as he pleases, but he should have a nurse or a member of the family supply the drug as he needs it.

Oral administration, whenever possible, should precede the use of drugs by hypodermic injection. Sometimes the needle habit is as bad as the drug habit.

2. Rogers, H.: *The Care of the Patient with Advanced Cancer, in Cancer: A Manual for Practitioners*, Boston, Rumford Press, 1940, pp. 244-252.

3. Daland, E. M.: *The Relief of Pain in Cancer Patients*, Pub. Health Rep., 1937, supp. 121, pp. 1-5.

Hypodermics require the services of a trained person. If they are used unnecessarily this may be the reason for keeping the victim in the hospital rather than at home, or it may necessitate the employment of a nurse before she is actually needed. Oral administration of the same amount of drug is slower to show results and gives approximately two thirds of the benefit produced by hypodermic injection. Sterile hypodermic injections of water should be given only as a test of the need for opiates and should never be used for treatment.

Acetylsalicylic acid is an exceedingly valuable drug in the relief of pain from many types of cancer. It can be given in doses of 0.3 or 0.6 Gm. (5 or 10 grains) every three or four hours. It is less irritating to the stomach than the other salicylates. Contrary to the opinion of many laymen it is apparently not harmful to the heart in reasonable quantities. It is sometimes more effective in combination with acetophenetidin and caffeine.

Acetophenetidin and acetanilid are not good drugs for the relief of the pain from cancer. They are not as effective for long use, and both may produce toxic symptoms if large doses are given over a twenty-four hour period.

Cobra venom is a nonnarcotic drug that has been widely advocated for relief of severe pain. Intramuscular injections of 1 or 2 cc. are given once a day for seven days, then single injections are given every three or four days. The results as reported from different clinics are variable. In my hands it has proved of little benefit.

Codeine is perhaps the most useful of the narcotics. It may be habit forming⁴ but is less likely to be so than is morphine. For the relief of distressing cough it may be used in as small doses as 0.015 Gm. ($\frac{1}{4}$ grain), but for pain 0.03 Gm. ($\frac{1}{2}$ grain) is the smallest effective dose. It may be given every three or four hours. Many physicians consider that acetylsalicylic acid administered with codeine makes the latter more effective and longer lasting. I have found this true in some cases but not consistently. The administration of acetylsalicylic acid can be alternated with that of codeine to effectively lengthen the time between the doses of codeine. Doses of 0.06 Gm. (1 grain) may be given as necessary. However, 0.06 Gm. (1 grain) of codeine is not twice as effective as 0.03 Gm. ($\frac{1}{2}$ grain), and it is probably better to give the smaller amount more frequently.

If the drugs which have been mentioned are used judiciously it may never be necessary to call on the more powerful narcotics. Morphine is the cheapest and by far the most useful of this group. The oral administration of 0.008 Gm. ($\frac{1}{8}$ grain) is of little more value than codeine 0.03 Gm. ($\frac{1}{2}$ grain). It is usually necessary to give 0.010 Gm. ($\frac{1}{6}$ grain) or often 0.016 Gm. ($\frac{1}{4}$ grain) every three or four hours to relieve severe pain. Lesser amounts are required if hypodermic injections are used, as has been stated previously.

Morphine is habit forming and must be administered with care. Habituation is not easily cured. It tends to cause constipation and may result in nausea and vomiting; sometimes patients who take the drug complain of itching.

Morphine not only relieves pain but is a hypnotic and produces sleep. It should not be given for the latter effect if other drugs can be used.

"Pantopon hydrochloride" (the total alkaloids of opium as soluble hydrochloride) has nearly the same effect as morphine but fewer side effects. It is useful in those patients who are susceptible to morphine and is given in doses of 0.01 Gm. ($\frac{1}{10}$ grain) to 0.02 Gm. ($\frac{1}{5}$ grain).

Dihydromorphinone hydrochloride ("dilaudid hydrochloride" N. N. R.⁵) has certain advantages over morphine. The dosages are approximately one fifth those of morphine—0.0025 Gm. ($\frac{1}{24}$ grain) by mouth or 0.002 Gm. ($\frac{1}{32}$ grain) subcutaneously. The drug produces less hypnosis than does morphine, and a barbiturate may be required to produce sleep. There is less gastrointestinal distress, but the drug is a depressant to the respiratory system and causes more itching. It is not a good substitute for morphine once the latter has been used.

Meperidine hydrochloride ("demerol hydrochloride" N. N. R.) is a recently introduced narcotic which has a definite place with some patients. It has few side effects but is as habit forming as the others. It is used in 0.05 to 0.1 Gm. doses hypodermically.

Methyldihydromorphinone hydrochloride ("metopon hydrochloride") has recently been announced as a new narcotic for dealing with pain in cancer patients. Its use is still in the experimental stage, and I have had but little experience with it.

Heroin (diacetylmorphine) should be mentioned only to say that it has no place in the treatment of this type of case.

There are many drugs that are beneficial in the production of sleep and relaxation. Acetylsalicylic acid will help many patients. Phenobarbital, sodium pentobarbital, chloral hydrate, paraldehyde and bromides all have their place.

TREATMENT OF ULCERATED LESIONS

Certain cancers of the skin or near the surface of an organ may become ulcerated as a result of inadequate blood supply to the new cells. Necrosis and sloughing occur with a resulting bad odor. There is nothing contagious as far as the cancer is concerned in these ulcerations, but there is nearly always secondary infection. Surgical principles hold here as elsewhere. Discharge from an infected cancerous ulcer calls for the same care as that from an infected finger. Members of a family often ask whether it is necessary to boil the dishes and the clothing used by the cancer patient. They are told that the same care should be used as for any infection and that it is not necessary to boil dishes.

It is this secondary infection that causes so much pain in ulcerated cancers. It is amazing to note how much the patient is benefited by careful attention to clearing up these infections. Wet dressings of saline solution, chlorinated soda, Dakin's solution (sodium hypochlorite) or one of the protein solvents help to remove the necrotic tissue and reduce the infection. Dressings should be changed several times a day or as often as they become soiled. Gross necrotic tissue should be excised or picked off the lesion. If the infection is bad and not easily controlled the sulfonamide drugs or penicillin may be used.

RADIATION THERAPY

Radiation therapy offers palliation chiefly in cancer of the skin, mouth, breast and uterus. Sometimes far advanced cancers of the skin can be cured or retarded

4. Himmelsbach, C. K.; Andrews, H. L.; Felix, R. H.; Oberst, F. W., and Davenport, L. F.: Studies in Codeine Addiction, Pub. Health Rep., 1940, supp. 158, pp. 1-67.

5. Nathanson, I. T., and Daland, E. M.: The Use of Dilaudid in Treating Patients with Cancer, New England J. Med. 213: 741-746, 1935.

for years by properly administered irradiation, preferably roentgen therapy. Treatment thought to be palliative may turn out to be curative. Here, as in other types of cancer, the first assault is the most important, and once it fails there is little likelihood of much benefit. Ulcerated, bleeding cancer of the breast, considered too extensive for operative therapy, may be reduced in size and sometimes destroyed by irradiation. The benefit is usually temporary, but it may be many months before recurrence appears.

Bleeding from advanced cancers of the cervix and endometrium may be controlled for many months by roentgen therapy. In some instances the extent of roentgenologic destruction of the primary lesion is so great that further treatment directed toward cure can be given.

Many patients with inoperable metastases to the lymph nodes from the skin, mouth, breast and other organs are given radiation treatment with an attempt at palliation. Unfortunately, these metastatic nodes are not nearly as sensitive to radiation as the primary lesions, and little benefit may result. Since one cannot predict in which case benefit will occur, this method of treatment is advocated for all such patients. Somebody has made the remark that "the only incurable case is the one that has not been cured," thus suggesting that a trial of all appropriate forms of treatment is in order.

Radiation therapy may result in relief from pain in other than ulcerated lesions. Pain from osseous metastases may be relieved for long periods by a minimum of treatment. I have repeatedly observed relief from this type of pain after one or two treatments or within forty-eight hours. Pain from osseous metastases from cancer of the breast and prostate is more apt to be relieved than other types, although radiation therapy is worth trying in pain from other types of metastases to bone, as in cancer of the ovary, kidney and rectum.

Irradiation has little selective action on cancer of the stomach, intestine, rectum or pancreas. The amount of therapy required to show any effect on such lesions is so great that the patient cannot tolerate it.

RELIEF OF OBSTRUCTION

Indications for Operative Therapy.—Even though the cancer is incurable one must not lose sight of the fact that relief of obstruction may afford the patient great relief. However, it must be made certain that the attempt to give palliation does not increase the discomfort of the patient. Prolongation of life if pain cannot be relieved or if new troubles are produced does not answer the definition of the word palliation.

In operative treatment for abdominal cancer the presence of metastases in lymph nodes or in the liver should not deter the surgeon from resecting the primary lesion if it is technically removable. This applies to cancers of the stomach, of the bowel, and in particular of the rectum.

Tracheotomy.—There is no more gruesome thing in medical practice than to see a patient strangle to death from an obstructing lesion of the larynx. Tracheotomy should be performed as soon as the patient manifests early signs of stridor, cyanosis or distress. The operation can be performed with the patient under local anesthesia with ease, provided that the surgeon has not waited until the patient is moribund.

Gastrostomy.—Gastrostomy should be performed only after careful study. This operative procedure should be

reserved for obstruction of the pharynx, esophagus or cardia. It is never worth while in cancer of other parts of the stomach. If a man cannot swallow the same amount of concentrated liquid food that would be instilled into a gastrostomy tube, operative treatment should be considered. However, there should be a life expectancy of a few months or the operation will not be worth while. One should also decide how the patient will accept this new regimen and whether he will actually be happier with it. A gastrostomy will not give relief to the troublesome salivation and discharge from the primary lesion. There may be leakage from the opening which will cause discomfort. Frequent feedings are a great deal of trouble.

Colostomy.—Miles⁶ once wrote about the "kindly colostomy." Some colostomies may answer that description but others do not. Colostomy will give relief from an obstructing lesion of the rectum or sigmoid. It will not relieve symptoms of tenesmus, especially if the lesion is close to the sphincter, and it may have but little effect on bleeding. There will be little if any actual prolongation of life from this operation.

The best type of colostomy is performed by delivering a loop of sigmoid through the abdomen at the outer border of the left rectus muscle and by suturing the peritoneum, fascia and skin beneath the loop. Later the loop should be completely divided to prevent spilling over into the distal loop.

The patient can be taught to control the action of the colostomy by diet and by daily enemas. There is no necessity for wearing a colostomy bag if careful attention is given to a daily movement; nearly all my patients wear a small gauze pad and report that they have no difficulty with leakage during the day.

Gastric Operations.—It is not always possible to determine without operative study whether or not a cancer of the stomach is resectable. When the cancer is demonstrated roentgenologically and because a particularly large mass is palpable, some physicians will decide that an exploratory operation is inadvisable. However, it has been my experience that lesions of this type are as often resectable as not, for the low position and mobility of the mass makes it possible to palpate it. Any resectable mass should be removed even in the presence of irremovable nodes or metastases in the liver, as this will give many months of comfort.

It is a well established fact that neither anterior nor posterior gastroenterostomy is a satisfactory operation for obstructing cancer of the stomach. In many instances the stomach does not function, and when it does it is for a short time only, as the cancer quickly encroaches on the anastomosis.

Occasionally it is possible to transect the stomach above the growth. A Polya or Hofmeister anastomosis is performed, and the distal end of the stomach is closed with a double row of sutures. This is a satisfactory operation, for the anastomosis functions well and growth of the cancer may be retarded. The patient may be entirely relieved of his symptoms and may live many months. It should be pointed out here that a biopsy should be made wherever possible to establish absolute proof of the diagnosis. I recall 2 patients examined recently, in whom this operation was performed five years previously and in whom the nodes removed were reported as inflammatory. Obviously, the diagnosis was ulcer and not cancer, and the patients are well.

6. Miles, W. E.: Some Phases of Rectal Cancer: Cancer Symposium, Philadelphia, Clinical Congress of American College of Surgeons, Oct. 12, 1930.

Cystostomy.—Permanent cystostomy for relief of obstruction from cancer of the prostate is not required as often as it was a few years ago, because transurethral resection may accomplish as much. However, there is a definite place for this operation especially as an emergency measure.

Intestinal Short Circuits.—Whenever a malignant neoplasm encountered in the small or large intestine cannot be resected, any possible short circuit should be performed. This may be an enteroenterostomy, an ileocolostomy, an ileosigmoidostomy or more rarely a colocolostomy.

It should be emphasized that in advanced cancer of the rectum or a lesion which has already metastasized to the liver an abdominoperineal resection should be performed if the primary lesion can be resected. This will give excellent palliation; I recall 1 patient who survived four years.

Relief from Cancer of the Pancreas and Duodenum.—Much relief can be given a patient with jaundice due to cancer of the head of the pancreas or duodenum by performing an anastomosis between the distended gall-bladder and either the stomach or the duodenum, preferably the latter. The jaundice may clear up entirely, digestion may be improved and the itching may be relieved.

CASTRATION THERAPY

In the latter part of the nineteenth century Beatson⁷ noted that if the ovaries were removed from patients with an advanced stage of cancer of the breast there sometimes was regression of the disease. The operation was tried by many surgeons with variable success and was abandoned by many. In 1931 I reported the case⁸ of a patient at the Pondville Hospital with extensive osseous metastases from cancer of the breast. There was decided regeneration of all her bones following a small series of roentgen treatments to her pelvis for relief of pain. It was noted also that this patient stopped menstruating after the treatments, and it was believed that ovarian activity had been destroyed by the radiation. In a second patient being treated with colloidal lead at the Massachusetts General Hospital there was observed regeneration of the bones of the pelvis, spine and skull. At first the lead was given the credit, but later it was discovered that she had also received radiation therapy to the pelvis for pain and that she too had ceased to menstruate. Thus the one factor in common in the 2 cases was irradiation of the ovaries, and this appeared significant. A large number of patients were then given radiation therapy to the ovaries, and it was reported by Dresser and Pelletier⁹ that about 30 per cent of those who had not had their menopause exhibited regeneration of bones and disappearance of metastatic deposits in the bones and lungs. Many writers have reported the same results. It is apparent that effective irradiation may accomplish the same results as the surgical castration of Beatson.

Huggins¹⁰ has given evidence that definite regression of cancer of the prostate may occur if the testes are

removed. This operation has come to be a standard procedure in inoperable and recurrent cancer of this organ. Not only does the primary cancer regress, but frequently osseous metastases disappear temporarily and pain is promptly relieved. The general condition of the patient improves greatly.

HORMONAL THERAPY

Huggins¹¹ has demonstrated that estrogens given to the patient with cancer of the prostate will in many instances produce the same relief from symptoms and retardation of growth as does castration. Many urologists carry out both procedures as soon as a diagnosis of irremovable cancer of the prostate is made. Others perform castration and later give estrogens, usually diethylstilbestrol. All this treatment gives only temporary relief, and after a few months or a very few years control is lost and the patient dies of cancer.

The use of hormonal therapy in cases of advanced cancer of the breast has aroused a great deal of interest and curiosity. It has been observed that some patients are benefited by estrogens (female sex hormones) while others receive relief from androgens (male sex hormones). In some instances one type of therapy has produced results after the other has failed.

Nathanson¹² has stated that cancer of the breast untreated by other means and recurrent nodules of cancer of the breast manifest a tendency to shrink up and disappear on diethylstilbestrol therapy in many instances. Microscopic analyses prove that the cancer nodules are actually destroyed. Ulcerated lesions exhibit epithelial repair and healing of the ulcer. Lesions of the soft tissue are affected to a greater degree than are lesions in bone. In some cases the osseous metastases have progressed while those of soft parts have disappeared. These results all seem to be temporary, and there have been no cures. Nathanson's most satisfactory results were in patients over 60 years of age.

Loeser¹³ and Ulrich¹⁴ in 1939 called attention to the effect of testosterone propionate in the treatment of advanced carcinoma of the breast. Adair and Hermann¹⁵ reported that benefit was received by 4 of 11 patients treated with this drug. Three of the 4 were patients with osseous metastases, and 1 had involvement of soft parts only. Roentgen examinations revealed an increase in calcification in the bones coincident with relief from pain.

Adair¹⁶ has stated that "testosterone may be employed on female patients with breast cancer at any age, while the estrogen therapy must be strictly confined to patients of 60 years and older." Nathanson¹⁷ has suggested that "testosterone therapy may be akin to premenopausal ovariectomy, in that the androgens may inhibit the estrogens directly or ovarian function via the anterior pituitary."

These results from hormonal therapy are exceedingly interesting and important. For the first time medica-

ments given by the oral route (diethylstilbestrol) and by intramuscular injection (testosterone propionate) have actually exhibited microscopic evidence of their effect on cancer. This form of therapy thus far is only palliative, but it opens the way for important research directed toward permanent benefit.

NEUROSURGICAL MEASURES

The neurosurgeon has much to offer the cancer patient. When the pain is severe and unendurable it is sometimes possible to interrupt the neural paths of pain by various procedures. Since pain may be referred to adjacent areas, a careful study is necessary to determine which nerve or nerves are actually involved.

Injections of the second and third branches of the fifth nerve with alcohol have been performed for many years. Seldom do they produce complete or permanent relief, for, as stated by Hodgson,¹⁸ the disease may involve adjacent areas which are innervated by other nerves as well as the fifth.

Subarachnoid injections of alcohol are often of benefit for pain in the rectum, pelvis, sacrum and coccyx. The injection of 0.5 to 0.7 cc. of 95 per cent alcohol is given into the third or fourth lumbar space with the patient's hips elevated and the painful side uppermost. If the injection is successful relief occurs quickly but is frequently only transient.

Chordotomy is an operative measure in which the spinothalamic tract, the pain fiber tract, is divided in the anterolateral portion of the spinal cord. This operation is technically difficult and requires a well trained surgeon to perform it. In carefully selected patients relief from pain below the navel can usually be given. Complications from the operation are not uncommon and consist of urinary retention, decubitus ulcers and motor weakness of the extremities.

Rhizotomy or posterior root section may be performed for pain in the neck, lower part of the scalp and face with fairly good results.

Other procedures for relief of pain in patients with advanced cancer are intramedullary section of the fifth nerve tract, myelotomy, presacral nerve section and prefrontal lobotomy.

The operation known as "prefrontal lobectomy," which consists of the severance of the neuronal connections between the thalamus and the anterior part of the frontal lobes on both sides of the brain, was first devised by Egas Moniz¹⁹ and reported at the Second International Neurological Congress in London in 1935. Moniz found it useful in the treatment of certain chronic psychotic states which had been refractory to other forms of treatment. Freeman and Watts²⁰ introduced the operation in this country and established its usefulness in chronic depressions, especially agitated depressions; in severe chronic anxiety states, and particularly in severe chronic obsessive-compulsive states. Mixter and his co-workers,²¹ using a modified lateral approach,

confirmed Freeman's and Watts's results in agitated depressions.

Poppen,²² who greatly improved the precision of the operation by introducing an open approach which allowed guidance by the anatomic landmarks of the brain rather than merely by those of the skull, which had been used heretofore, recommended use of the operation for the treatment of intractable pain and reported a successfully treated case. Freeman and Watts²³ likewise reported successful control of unbearable pain by this operation. While prefrontal lobotomy does not reduce sensory and pain thresholds for external stimuli applied to the skin, it does divert deep internal pain of its harrowing and threatening quality. The patient still has pain, but it is meaningless.

I have had no experience with patients subjected to this operation, but I believe that the operation has a definite place in certain cases of intractable pain that cannot be relieved by other means.

SUMMARY

1. There is much that can be done for the patient with advanced cancer. He should be given the benefit of as radical an operation as can be performed safely, always with the hope that cure can be accomplished or, failing this, that palliation may be given.
2. Radiation treatment may be curative in many types of superficial cancer and palliative in advanced cancer of certain organs.
3. Medicaments should be prescribed in such a way that an adequate amount is given, but never more than the amount of pain warrants. Avoidance of an excess of narcotic drugs is the prevention of drug addiction.
4. Surgical relief of obstruction, neurosurgical measures for combating pain, castration therapy and the administration of male and female sex hormones all have a place in the treatment of this group of patients.

The Jubilee of the Electron.—Professor J. J. Thomson, in 1897 working in the Cavendish Laboratory at Cambridge, discovered that cathode rays consist of negatively charged particles (electrons, as they came to be known) many times smaller in size than the smallest atoms known. During the fifty years that have elapsed since that discovery, it has been established that electrons form an essential part of all matter. To mark the jubilee of the discovery of the electron, celebrations were held recently in London by the Institute of Physics and the Physical Society Engineers in collaboration with the Institution of Electrical Engineers. On the afternoon of Sept. 25, 1947, at the Royal Institution, Professor J. A. Crowther gave a lecture on the history and early development of the discovery. He was followed by Professor R. E. Peierls, who spoke on electrons in modern theoretical physics. In the evening a public lecture was delivered to a very large nontechnical audience at the Central Hall, Westminster, by Sir Clifford Paterson, director of the Research Laboratories of the General Electric Co., Ltd., on "The Electron Liberated." On the following day the Electron Jubilee Exhibition at the Science Museum, South Kensington, was formally opened. At the Institution of Electrical Engineers, a posthumous portrait of Sir J. J. Thomson painted by Mr. Francis Hodge, was unveiled by "J. J.'s" son, Sir George Thomson, who then addressed the assembly on the electron in research.—Jubilee of the Discovery of the Electron, *Nature*, December 1947.

Clinical Notes, Suggestions and New Instruments

FATAL REACTIONS TO INTRAVENOUS ADMINISTRATION OF AMINOPHYLLINE

Report of Three Cases

ELLIOTT BRESNICK, M.D.
WILLIAM K. WOODARD, M.D.
and
CLIFFORD B. SAGEMAN, M.D.
Brookline, Mass.

Aminophylline (theophylline ethylenediamine) has received widespread acceptance as a bronchodilator in the treatment of both bronchial and cardiac asthma,¹ as a diuretic in cardiac congestive failure² and as a coronary vasodilator in the treatment of coronary occlusion³ and angina pectoris.⁴ Because of its irritating action on the gastrointestinal tract, its therapeutic effectiveness by mouth, even in enteric-coated capsules, is limited.⁵ In bronchial asthma, in fact, it cannot be tolerated by mouth in doses large enough to relieve bronchospasm, whereas, when it is administered intravenously, the effect is usually prompt and satisfactory.¹ The intravenous route has therefore come to be the method of choice whenever the urgency of the situation demanded prompt and effective action. Particularly has this been true in the treatment of acute myocardial infarction.

There have been only a few reports of toxic effects from aminophylline administered intravenously. A review of the literature discloses but 3 fatal cases, all cited by Merrill.⁶ One of these was of a man of 52, who was under treatment for acute myocardial infarction. He died suddenly during the injection, when only 0.1 Gm. of aminophylline had been introduced into the vein. The second case was of a man of 70, who had acute cardiac decompensation. (The dose is not mentioned.) The third case was of a man of 73 with hypertension, bronchiectasis and status asthmaticus, who died thirty seconds after the intravenous injection of 10 cc. (0.24 Gm.) of aminophylline.

We present 3 more fatal reactions following the use of aminophylline intravenously.

REPORT OF CASES

CASE 1.—E. G., a 74 year old white man, was admitted to the third medical service Oct. 7, 1946 because of pain in the chest of nine hours' duration. He had experienced typical episodes of coronary occlusion six years and again three weeks

From the First and Third (Tufts) Medical Services, Boston City Hospital, and the Department of Medicine, Tufts College Medical School. Charlton Research Fellow, Tufts College Medical School, and Volunteer Assistant in Medicine, Boston City Hospital, (Dr. Bresnick) and interns, First and Third Medical Services, Boston City Hospital (Dr. Woodard and Dr. Sageman).

Helpful criticisms and suggestions were made by Dr. James M. Faulkner, Professor of Medicine, Tufts College Medical School, and Director of First and Third Medical Services, Boston City Hospital. Dr. Faulkner has since become Dean of Boston University School of Medicine.

before entry and had received digitalis, 0.1 Gm. daily, since the last one. On the day of entry he was awakened in the morning from a sound sleep by a severe, crushing substernal pain, radiating over the entire chest and down both arms, and accompanied by severe dyspnea and orthopnea.

Physical examination revealed a moderately cyanotic, thin, elderly man in respiratory distress, with cold, clammy skin. Pulse and blood pressure were unobtainable. The apical heart rate was 120 per minute. Heart sounds were muffled, and a protodiastolic gallop could be heard at the apex. Both pulmonary fields were entirely filled with moist, bubbling rales. Oxygen was administered immediately through a nasal catheter. Caffeine and nikethamide administered intravenously seemed to effect slight improvement in his general appearance. Aminophylline, 7½ grains (0.48 Gm.) in 20 cc., was started intravenously. After 15 cc. (0.36 Gm.) had been injected at a "slow" but unmeasured rate, the patient suddenly gasped and became livid. He clutched at his chest and gasped for air. The needle was immediately withdrawn. The patient stiffened and had two brief generalized convulsions. The heart sounds at this time could not be heard. He then became limp. Artificial respiration and intracardiac injection of epinephrine failed to revive him, and he was pronounced dead twenty-five minutes after arrival on the ward.

CASE 2.—J. Z., a 54 year old white man, entered the third medical service Oct. 16, 1946 because of crushing substernal pain of one hour's duration. He was apparently in perfect health until one hour prior to entry when, while sitting quietly at work, he was suddenly seized with a "smothering" sensation beneath the sternum. He became apprehensive and covered with cold perspiration. The smothering sensation gradually changed to a crushing, substernal, nonradiating pain. With this he felt extremely short of breath. He was then rushed to the hospital.

He was a slightly obese, cold, cyanotic, middle-aged man, perspiring profusely. Pulse and blood pressure could not be obtained. Heart sounds were distant and the rate was 120 per minute. Rhythm was regular. The heart did not appear clinically to be enlarged. There were fine, moist rales at both bases. An electrocardiogram taken soon after entry showed changes consistent with an acute anterior myocardial infarction. He was given oxygen by nasal catheter, atropine, ½₁₀₀ grain (0.06 mg.) and merperidine hydrochloride, 100 mg. intramuscularly. After receiving papaverine, 1 grain (60 mg.), intravenously, he appeared more comfortable, the radial pulse could be felt, and the general picture appeared much more encouraging, although the blood pressure was still unobtainable. Intravenous injection of aminophylline, 7½ grains (0.48 Gm.) in 20 cc., was begun at a "slow" but unmeasured rate. After 10 cc. (0.24 Gm.) had been injected, the patient suddenly clutched at his chest and gasped, becoming deeply cyanotic. The needle was immediately withdrawn from the vein. He continued to gasp spasmodically, using all accessory muscles of respiration, and a white froth appeared on his lips. Heart sounds at this time could not be heard, and the pulse was again unobtainable. Gasping inspiratory movements continued, at ever increasing intervals up to forty-five seconds, for approximately five minutes. During this period there were three very brief generalized convulsions. In the meantime artificial respiration was maintained, and 1 cc. of 1:1,000 epinephrine was injected into the heart without benefit. Resuscitation measures were discontinued, and the patient was pronounced dead one hour and fifteen minutes after arrival on the ward.

CASE 3.—E. M., 31 year old Italian housewife, was admitted on May 31, 1946 to the first medical service for the fourth time since August 1945. Each admission was due to uremia on the basis of chronic pyelonephritis, accompanied by severe anemia, albuminuria and a fixed urinary specific gravity. On her final admission the findings were essentially the same, with nonprotein nitrogen climbing from 186 to 283 mg. and carbon dioxide-combining power remaining at 19 to 23 volumes per cent despite intravenous administration of lactate.

Shortly after entry a pericardial friction rub became audible and steadily increased in intensity. Uremic frost soon appeared on her skin. Peripheral edema increased, and on the second hospital day acute pulmonary edema developed. It was felt

that rapid digitalization might afford temporary relief. (She had had no previous digitalis.) Aminophylline, $7\frac{1}{2}$ grains (0.48 Gm.) in 20 cc., was mixed with 1 cc. (0.65 mg.) of strophanthin. This mixture was injected "slowly" although not at a measured rate, into the left antecubital vein. After approximately 5 cc. (0.11 Gm. of aminophylline and 0.15 mg. of strophanthin) had been injected, the patient's eyes rolled upward, her left arm began to twitch spasmodically, and she progressed into a generalized convulsive seizure of short duration. At this time no pulse could be felt or heart sounds heard. Her entire body remained rigid thereafter, and despite artificial respiration, about one minute later respirations also ceased.

COMMENT

It is to be emphasized that in all of these occasions the intravenous injection of aminophylline was associated with sudden exitus in patients who were not moribund at the beginning of the injection. All had previous evidence of coronary disease or severe myocardial damage with failure. The mode of death suggested cardiac standstill or ventricular fibrillation. It is recognized⁷ that aminophylline has a direct stimulating effect on the myocardium, that it increases cardiac work and that it is a coronary vasodilator. The question has been raised⁸ whether the coronary vasodilating effect of aminophylline is simply a response to increased metabolic demands of the myocardium comparable to the reaction to epinephrine. Even if increased metabolic requirements are not the only factor by which aminophylline produces coronary vasodilatation, if the coronary arteries are incapable of dilating sufficiently to keep pace with the enhanced metabolic demands, any drug which stimulates the myocardium may precipitate coronary insufficiency. In the presence of occlusive coronary disease such a drug might favor the development of ectopic arrhythmias such as is observed, for example, after the injection of epinephrine. Merrill,⁹ in commenting on his experiences with intravenous administration of aminophylline, stated that "the suddenness of the death resembles that seen when epinephrine hydrochloride has been given undiluted intravenously, in which case death has been due to ventricular fibrillation."

The fact that the sudden death occurring in association with the intravenous injection of organic mercurial-theophylline compounds appears to be due to ventricular fibrillation⁸ raises the interesting question whether the theophylline component could be the exciting factor in provoking abnormal ventricular irritability. However, clinical experience has shown that sudden death may occur with intravenous injection of organic mercurials not containing theophylline,¹⁰ and experimental observations on cats¹¹ indicate that adding theophylline to an organic mercurial does not appear to enhance its effect on ventricular irritability.

The total dose of aminophylline administered does not seem to be important, within therapeutic limits, the fatal dose having varied from 0.1 Gm. to 0.36 Gm. It is quite possible that the speed of injection is more important. It has been repeatedly observed that too rapid intravenous injections of aminophylline may evoke toxic symptoms referable to the central nervous system (hyperpnea, vertigo, faintness).⁹ In the 3 cases cited in this paper the injections were not timed with a watch although the interns who gave them stated that they were given "slowly."

If aminophylline were a dangerous drug to give intravenously, one would have expected more reports of disasters attending its use. Allergists who have used it freely for years in the treatment of bronchial asthma report no serious toxic reactions to it. Our experience may mean, however, that in the presence of coronary disease an additional hazard is present which necessitates caution and very slow injection.

SUMMARY

Three cases of sudden death in association with the intravenous injection of aminophylline are reported. The possible mechanism of death is discussed.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, Secretary.

FIBERGLAS-FILLED SLEEPYTIME PILLOW ACCEPTABLE

Manufacturer: The P. R. Mitchell Company, Spring Grove and Harrison Avenues, Cincinnati 22.

The Fiberglass-Filled Sleepytime Pillow is designed for the use of patients who are allergic to feathers and other materials that might ordinarily be used in stuffing pillows. The material used in the present case is essentially glass in the form of fibers about 2 microns in average diameter. Fibers of this thickness

or less under these conditions do not break easily and are extremely resilient. The latter fact is conveniently demonstrated by the ease with which the pillow fluffs up and returns to its original size when shaken. The resistance of the fibers to fracture under these conditions was demonstrated by a test in which a bowling ball (weight, 7.5 Kg.; diameter, 20 cm.) was allowed to fall on the pillow some 50,000 times. Afterward, comparison of the contents of the pillow with untested controls showed no appreciable difference between them.

The investigator for the Council reported that the pillows were well made, that the ticking was of good quality and that the amount of filling seemed to be right for a patient's comfort.

The Council voted to include the Fiberglass-Filled Sleepytime Pillow in its list of accepted devices.

EMERSON LUNG IMMOBILIZING CHAMBER ACCEPTABLE

Manufacturer: J. H. Emerson Company, 22 Cottage Park Avenue, Cambridge, Mass.

The Emerson Lung Immobilizing Chamber is essentially a horizontal, cylindrical chamber, large enough to enclose a human adult completely and equipped with a pump that applies alternating positive and negative pressures to the entire body. Although at first sight similar to the tank type of respirator, it operates on a radically different principle developed by Barach.

To illustrate this principle one may imagine an open bottle standing under a large bell jar; if air is removed from the bell jar, the air in the bottle participates in the expansion of the air outside the bottle, and there is a movement of air outward through the neck of the bottle. In the same way, if the human subject is entirely inside the chamber, pumping some of the air out of the chamber must result in the expansion of the air in the patient's lungs and there must follow a movement of air outward through the patient's trachea. When air is readmitted to the chamber, especially under positive pressure, there will be some compression of the air in the patient's lungs and an inward movement of air through his trachea. These movements of air in and out of the patient's lungs need not be accompanied

by movements of either the diaphragm or the thoracic wall if the alternations of pressure are sufficiently slow. If the alternations are fast, however, certain dynamic factors have to be taken into account in order to hold the diaphragmatic and thoracic movements in abeyance. The Emerson Lung Immobilizing Chamber is designed to do this by timing the pressure changes on successive parts of the body; it thus solves the problem of making air move in and out of the patient's lungs while the lungs are actually motionless. It is assumed that immobilization promotes localization and healing of disease processes in the lungs.

The idea was commented on editorially in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Feb. 2, 1946, page 281. The manufacturer claims only that when a patient is enclosed in it the device will provide alternating positive and negative pressures both at the nose and mouth and at the chest of the patient, amounting to about 55 mm. of mercury positive and 55 mm. negative, at about 25 cycles per minute. These positive and negative pressures arrive at the head region (nose and mouth) a fraction of a second before they arrive at the surface of the chest.

This delay is an essential feature of the apparatus and is achieved by means of a partition that separates the head compartment from the body compartment. Air from the motor-blower unit enters the head end of the chamber and has to pass through an adjustable opening at the level of the neck to reach the body compartment. In this way the pressure arriving at the inner surface of the chest wall and the upper surface of the diaphragm is made equal to that which is exerted on the outer surface of the thorax and abdomen. The difference in pressure needed to overcome resistance in the tracheobronchial tree, according to Barach, was found to be 4 to 10 cm. of water in the majority of cases of pulmonary tuberculosis. By delivering the air wave to the head end of the chamber before entrance into the body compartment, the application of pressure on each side of the chest wall is also made simultaneously. Observation of patients with pulmonary tuberculosis enclosed in a chamber of this type revealed no chest movement. This has been demonstrated by visual observation, moving pictures and x-ray of the chest during positive and negative phases of pressure.

Emerson Lung Immobilizing Chamber.

By adjusting the size of the opening between head and body compartments, it is possible to accommodate somewhat to variations in the resistance to the movement of air in the patient's respiratory passages. There is a limit to this, however, and it is stated that immobilization of the lung cannot be obtained in patients with bronchial asthma, pulmonary emphysema, pulmonary fibrosis, or in any case in which respiratory obstruction is present.

The apparatus worked well in the hands of a clinician who investigated it for the Council. One patient had marked claustrophobia and was much upset when he was placed in the chamber. In spite of reassurance, the man persistently got very excited while in the chamber, so that after a few trial treatments the investigator decided to discontinue them. In general, the investigation revealed that there is a sensation of complete relaxation, and this persists for some time after the patient leaves the chamber. As soon as the patient is disconnected from the chamber he promptly resumes spontaneous breathing. A study of the heart rate revealed that there is a definite slowing of the pulse rate of 10 to 15 beats per minute. The blood pressure shows a tendency to fall from 10 to 30 mm. of mercury pressure, and return to the original level within an hour after the treatment. Electrocardiographic studies of the heart before, during and after the treatment reveals no appreciable change, except an increase in the amplitude of the T wave after the treatment.

The chamber is air-conditioned by thermostatic control of temperature which can be regulated from the inside. Portholes are present that can be opened by the patient in the event that

the circulation of air stops through turning off of the electricity or other reason. The chamber is equipped with a talking device by which the patient may communicate to the outside or listen to the radio.

The Council on Physical Medicine voted to include the Emerson Lung Immobilizing Chamber in its list of accepted devices.

Council on Pharmacy and Chemistry

A STATEMENT

When the American Medical Association was reorganized in 1901 leaders of the profession recognized the responsibility it must assume to protect its members from misleading and, at times, dangerous medical advertising. In 1905 the Council on Pharmacy and Chemistry was formed; its members were charged with the establishment of a series of principles that would aid in differentiating between useful and useless drugs, between those sold with honest and dishonest claims; between those based on scientific evidence and those sold without such evidence.

By action of the House of Delegates, the advertising pages of *THE JOURNAL* were subjected to painstaking scrutiny; as a result many advertisements were deleted. The elimination resulted in considerable financial sacrifice. Editorially and by its actions *THE JOURNAL* wholeheartedly supported the principles established by the Council on Pharmacy and Chemistry.

As might have been expected, the Board of Trustees and other officers of the Association were bitterly attacked, criticized and condemned for this action that was motivated only by a desire to further medical progress. The General Manager and Editor of *THE JOURNAL*, Dr. George H. Simmons, was caricatured and subjected to vilification. Dr. Frank Billings was threatened with libel suits; some members of the Council were subjected to intimidation. Yet neither *THE JOURNAL* nor the officers of the Association wavered in their decision. Never once did any official of the Association attempt to make the Council deviate from the decisions it believed warranted.

With hearty appreciation the members of the Council record this acknowledgment of cooperation. At times decisions were made with the realization that their significance would not be fully apparent without careful study. The supporters of the Council, who now include a vast majority of the members of the Association, have shown no indication of a desire that it relax or relinquish its activities. Without this support the Council's work would have been much more arduous, perhaps some of it even impossible.

Until recently only two of the state medical journals, those of New York and Illinois, were not members of the Cooperative Medical Advertising Bureau which follows the standards established by the Council in its acceptance of advertising. More recently two others, California and Rhode Island have been added to the list of those that do not enjoy membership in the Cooperative Medical Advertising Bureau. This failure to maintain membership in the Bureau that follows Council standards is an action the Council greatly regrets, believing, as it must, that physicians who are members of the American Medical Association recognize the scrupulously judicious and scientific attitude with which it attempts to administer its obligation.

The Council on Pharmacy and Chemistry wishes to express its appreciation of the help afforded by the Board of Trustees, *THE JOURNAL* and other mutually interested units of the American Medical Association. Such unswerving assistance has been the nucleus of an understanding that has withstood all attacks in the past and must continue to do so in the future.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - CHICAGO 10, ILL.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - Twelve dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, FEBRUARY 7, 1948

SCIENTIFIC MEDICAL ADVERTISING

On page 399 of this issue of THE JOURNAL appears an official statement by the Council on Pharmacy and Chemistry of the American Medical Association relative to the advertising in medical periodicals of products which have been considered by that Council. For almost fifty years the Council on Pharmacy and Chemistry has had the support of the House of Delegates of the American Medical Association, which has spoken with one voice as the representative body in American medicine to indicate that the vast majority of American physicians want to use pharmaceutical products of known composition sold without false, fraudulent or exaggerated claims. The Council was established in February 1905 and has served notably for the advancement of medical science and particularly for scientific therapy since that time. The position that it occupies in American medicine has been the envy of medical leaders in every country in the world. Its work has received the endorsement of governmental agencies engaged in similar efforts. In brief, the Council promotes basic or fundamental research on the use of new products and technics, evaluates the laboratory and clinical evidence offered on behalf of pharmaceutical products and encourages the use of rational therapeutics while discouraging the use of irrational preparations and technics.

Occasionally the work of the Council on Medical Education and Hospitals, the Council on Pharmacy and Chemistry and similar committees and councils comes into conflict with vested interests, private agencies and commercial organizations, which do everything possible to defeat its idealistic objectives. The rapid growth both in circulation and influence of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has sometimes made it the target of attack of privately owned medical publications. Some of the publications of state medical societies found it difficult in the past to maintain their incomes because these publications, like THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, wished to meet the ethical standards which

were an integral part of the advancement of American medicine. From Dr. J. N. McCormack of Kentucky about 1910 the House of Delegates received a resolution urging the Board of Trustees to give every possible aid to the state medical journals to permit them to advance coincidentally with the national publications of the Association. As a part of this effort, the headquarters of the American Medical Association developed a system of sending to all of the state medical journals weekly abstracts of the original articles published in THE JOURNAL and also condensations of the actions of its official bodies and of the editorials in THE JOURNAL. From this effort ultimately developed the American Medical Association's news and press sheet, which is now being sent not only to all of the medical publications of the country but also to the lay press as well. Next came a motion to create a bureau of advertising to aid the periodicals that wished to conduct themselves in accord with the principles of the councils of the American Medical Association.

The Board of Trustees in 1913 established the Cooperative Medical Advertising Bureau to aid the state medical journals in securing acceptable advertising. At first the movement was heartily welcomed by the publishers of the state medical periodicals. Then, for various reasons, some leaders of state medical societies began to urge those responsible for the administration of these societies to discontinue the relationship of the state medical journals with the Cooperative Medical Advertising Bureau and to substitute therefor independent committees and agencies. Most persistent in the failure to function with the Cooperative Medical Advertising Bureau has been the *Illinois Medical Journal*, which never has followed the standards of the various scientific councils of the American Medical Association in the acceptance of advertising. Second on the list is the *New York State Journal of Medicine*, which for a brief period agreed to abide by the decisions of the councils which differentiate scientific from unscientific products but which thereafter preferred to have the profits to be derived from the publication of advertisements of unaccepted products. More recently the *Rhode Island Medical Journal* and *California Medicine* have defected from the standards of the councils and have established their own mechanisms for approving or disapproving advertisements which might be submitted to them or solicited by their independent advertising representatives or agencies. Presumably the decisions rest in each instance on the actions of special committees on publications and on the subsequent endorsement of the actions of these committees by the councils of the societies.

The first issue of *California Medicine* following its resignation from the Cooperative Bureau was its issue.

for October 1947. In that issue appeared the announcements of a dozen products which had not been accepted by the Council on Pharmacy and Chemistry. By January 1948 the number had increased to more than twenty-five products. Moreover, some of the ethical manufacturers who regularly submit through the Cooperative Medical Advertising Bureau products accepted by the councils for advertising in state medical journals apparently gave to the California, Illinois, New York and Rhode Island journals almost wholly products that were not accepted. Of course the California journal is still in the amateur stage as far as this debarkation into the promotion of unscientific products is concerned; perhaps it can learn from Illinois and New York, since their lists have been more expansive and extensive than those of California and Rhode Island. Rhode Island's small membership makes it less attractive as a medium for advertising to the medical profession; therefore, it may have far more to lose than to gain by its departure from the Cooperative Medical Advertising Bureau.

THE JOURNAL commented on this situation previously in October 1943. At that time THE JOURNAL pointed out that the battle for scientific therapy is a difficult one. As long as any considerable part of the medical profession helps to extend the blight of the falsely exploited proprietary medicine, this battle is more difficult. In any war the most dangerous attack is the attack from the inside; the story of the Trojan horse is too well known to require repetition. The threat most difficult to meet is the threat from those who are presumed to be friends. The time should long since have passed when leaders of medical organizations consent to permit the exploiters of unscientific proprietary remedies to pay the bulk of the cost of publishing and printing medical journals that are supposed to represent scientific medicine. Our state societies need efficient executive offices, public relations services and all the other mechanisms that have come to be a part of efficient operation, but they should not hope to pay for such procedures by the profits derived from unscientific exploitation of their membership and of their public who depend on that membership. Are the business managers or committees of the four medical journals that have been listed better equipped to judge what is scientific and honest in materia medica and therapeutics than are the Council on Pharmacy and Chemistry? The vast majority of physicians in the United States do not think so. The responsibility rests, however, not on these employees of these organizations but on the physicians who constitute their committees of publications, on the councils of the societies that endorse the actions of these committees and, finally, on the houses of delegates of these state societies that have not

apparently given sufficient thought to the extent to which they also share in the perpetuation of fraudulent and unscientific preparations and commercialized medicine. Nothing is so important to medicine today as its good name. That good name is its most important asset when it comes before the bar of public opinion.

PROTEINS AND AMINO ACIDS IN SURGERY

An important advance in surgery is the recognition of the relation of the patient's state of nutrition to his chances of withstanding the shock of operative procedures, of resisting postoperative infection, of achieving primary closure of operative wounds and of avoiding postoperative complications. Recently the concept of protein deficiency as an important factor in the complications of surgery has received increasing recognition.

Hoffman¹ presented a critical review discussing the role of proteins and amino acids in surgery. Several circumstances may lead to a protein deficiency in the preoperative and postoperative surgical patient: (1) decreased dietary intake of protein as in famine, poverty, obstructive conditions in the gastrointestinal tract and repeated vomiting; (2) decreased absorption of protein as in diarrheal states or ulcerative disease of the intestine and in conditions associated with diversion or absence of pancreatic juice or bile from the intestinal tract; (3) decreased formation of blood proteins due to disease of the liver; (4) increased loss of protein as in kidney disease, burns, hemorrhages, excessive vomiting or diarrhea or through suction drainage through enteric tubes, and (5) increased requirements of protein as in hyperthyroidism, fever, pregnancy and leukemia.

The clinical manifestations of protein deficiency include peripheral edema in the dependent portions of the body and the regions of low elastic tissue pressure. Edema of the lungs and edema of the intestine, particularly at the site of stomas, occur commonly. Other manifestations are diminished intestinal motility often with distention, delayed wound healing, hepatic damage, increased susceptibility to infection, shock, anemia and increased tendency to thrombosis and embolism.

The determination of concentration of total serum proteins can be used as a reliable index of the state of protein nutrition. The normal serum protein concentration ranges from 6.5 to 8.0 Gm. per hundred cubic centimeters, but here a note of caution is necessary: if there is a decreased plasma volume this value is not entirely reliable. In such circumstances it may be necessary to ascertain the total circulating protein by determining the plasma volume by one of the dye methods and multiplying this value in cubic centimeters by the concentrations of protein in grams per cubic centimeter.

1. Hoffman, W. S.: The Clinical Significance of Proteins and Amino Acids in Surgery, *J. Internat. Coll. Surgeons* 10: 492 (Sept.-Oct.) 1947.

The treatment suggested by Hoffman¹ for the patient with depleted protein stores is a diet high enough in protein to produce a positive nitrogen balance. As much as 125 Gm. of protein may be given daily using ordinary foods; unfortunately, in most cases of protein deficiency, even if the patient is able to take food orally, the limitations of appetite and volume capacity of the stomach make a high intake of natural foods impossible. By using concentrated protein foods such as dried whole milk, soybean powder, dried brewers' yeast or one of the powdered protein concentrates prepared from lactalbumin or hydrolysates of casein the protein of the diet may be increased to 300 Gm. per day without increasing the bulk of the diet.

In those patients unable to take adequate quantities of protein by mouth, the parenteral administration of mixtures of amino acids has been successful. Patients can be maintained in positive nitrogen balance for a limited period with hydrolysates of casein as the sole source of nitrogen. Clinical experience indicates that parenteral injections of amino acids are an important nutritional advance but are impractical when used as the only source of nitrogen for long periods of time. When they are used to supplement transfusions and high oral nitrogen intake, much better and faster clinical improvement is achieved.

Factors which limit the use of most of the available preparations for parenteral protein alimentation are the occurrence of headache, nausea, vomiting, flushing and venous thrombosis. These reactions are frequent when casein hydrolysates are given at rapid rates. Recent studies² in both dogs and human subjects indicate that glutamic and aspartic acids are responsible in part for these reactions, which result from the intravenous administration of casein digests; amino acid mixtures with little or none of these dicarboxylic acids are well tolerated.

With casein hydrolysates, the giving of enough material intravenously to supply the nitrogen and caloric needs is difficult. Available evidence indicates that approximately 1,000 calories plus adequate biologically utilizable nitrogen per day is adequate to produce nitrogen balance. However, there are few data regarding the optimum daily caloric intake necessary to produce the most efficient retention of nitrogen in patients in various protein deficiency states. Future advances in the science of nutrition will probably provide the surgeon with means of reducing the surgical risk and increasing the rate of recovery from surgical operations.

Current Comment

UTILIZATION OF ASCORBIC ACID

With the advent of vitamins in chemically pure form, the question has naturally arisen regarding the comparative nutritive value of the natural versus the synthetic forms of vitamins. Not only has there been presumptive superiority of certain of the vitamins as they occur in natural fruits and grains, but a recent report¹ describes the considerably greater vitamin C (ascorbic acid) potency of natural and fortified orange juices when assayed by the dental biologic assay than could be accounted for by the ascorbic acid determined therein by quantitative chemical analysis. Melnick and his co-workers² have thrown light on this general problem by reexamining the comparative stability of ascorbic acid in aqueous solution and in apple juice. Under controlled conditions of hydrogen ion (p_H) and initial concentration, the vitamin C in apple juice is far more stable when stored at high summer temperature than is the ascorbic acid in aqueous solution under like conditions. However, when the availability to the organism and the influence on the response to test doses of ascorbic acid was studied in human subjects, there was little if any difference in the behavior of the agent administered in water or that given in apple juice. Not only can apple juice be safely fortified with vitamin C, but also synthetic ascorbic acid administered for therapeutic purposes is absorbed and utilized by the body as well as that from natural sources.

FEDERAL TRADE COMMISSION SURVEYS ADVERTISEMENTS

The Federal Trade Commission¹ conducts a continuing survey of radio and periodical advertising to detect advertisements that may be false or misleading. During the last fiscal year 412,950 newspaper and other periodical advertisements and 641,402 radio commercial continuities were examined, and thousands of advertisements and broadcasting statements were designated for further study. Analysis of these questioned advertisements disclosed that 55.8 per cent of them pertained to drugs, 16.9 per cent to cosmetics, 5.9 per cent to food (human and animal), 2.2 per cent each to tobacco products and devices, 2 per cent to automobiles, radios, refrigerators and other equipment, 1.4 per cent to specialty and novelty goods, 1.1 per cent to home study courses and 12.5 per cent to miscellaneous products. These percentages seem to confirm the opinion that the drug business is by far the most usual approach to misleading advertisements. However, the special interest of investigators in health and the possibility of developing scientific evidence to support or deny claims may have been important factors.

ORGANIZATION SECTION

Official Notes

"PHYSICIANS AND SCHOOLS"

A brochure outlining the relationship of the physician to the school health and physical education program is now available for distribution by the Bureau of Health Education.

The pamphlet is entitled "Physicians and Schools" and is the report of the National Conference on this subject held at Highland Park, Ill., October 1947. Recommendations on school health services, school health studies, inservice and preservice education and medical guidance in physical education and athletics are made.

A complimentary copy will be sent to physicians, teachers and public health workers on request. Additional copies will be priced at 25 cents each.

TELEVISION PROGRAMS EXTENDED

Since late autumn weekly health news telecasts have been presented over station WBKB, Chicago, by the Bureau of Health Education. Recently arrangements were completed to present weekly educational programs over this station, as a result of allotment of more time. The health news presentations, consuming from five to eight minutes, were based on items contained in the weekly newsletter of the American Medical Association. Frequently it was possible to have special scripts prepared to read over a silent film. The new educational program represents more active participation, since heretofore these were given at two week intervals. Presentation time has been extended to fifteen minutes. Following are subjects to be telecast in February:

February 9—School health inspection.
February 16—Smoke pollution.
February 23—Visual education.

RECORDING MEMBERSHIP AND FELLOWSHIP IN THE NEW DIRECTORY

The Information Cards received from physicians who have listed their data for the new, Eighteenth Edition of the "AMERICAN MEDICAL DIRECTORY," indicate increasingly that many are not aware of the difference between "Membership" and "Fellowship" in the American Medical Association.

Here are the official definitions:

Every MEMBER in good standing in the constituent medical association of the state in which he is engaged in practice whose name is officially reported to the Secretary of the American Medical Association for enrolment becomes automatically a MEMBER of the American Medical Association and is not called on, as such, to pay any dues or to contribute financially to the Association.

MEMBERS of the American Medical Association are eligible to apply for FELLOWSHIP.

To qualify as a FELLOW, a MEMBER in good standing is required to make formal application for FELLOWSHIP, to pay FELLOWSHIP dues and to subscribe for *The Journal*. Applications must be approved by the Judicial Council. Fellowship dues and subscription to *The Journal* are both included

in the one annual payment of \$12, which is the cost of *The Journal* to subscribers who are not FELLOWS.

MEMBERS of constituent state medical associations pay dues to those bodies, but as MEMBERS they pay nothing to the American Medical Association. FELLOWS pay dues and subscription to *The Journal* in the sum of \$12 a year, which has nothing to do with county or state dues.

According to an amendment to the By-Laws of the American Medical Association, no physician may be officially recorded as a MEMBER of the American Medical Association except on the basis of membership in one constituent state medical association, and that one the association of the state in which the physician concerned maintains legal residence and engages in the practice of medicine.

Each Fellow receives a Fellowship Card from the Association annually as payment of his dues is recorded, which card is presented for admission to the Annual Meetings of the Association.

Physicians who are eligible for Fellowship should make formal application immediately so that they may attend the Chicago Session and so that a record of their Fellowship may be received in time to include the Fellowship symbol in their data listed in the new "AMERICAN MEDICAL DIRECTORY."

Washington Letter

(From a Special Correspondent)

Feb. 5, 1948.

This Session of Congress

This session of Congress ordinarily would be a short session because of the coming election, but there is so much legislation demanding immediate attention that it is doubtful if adjournment will come before July 1. A number of items on the congressional program will be considered more urgent than welfare or health, but the subjects must receive consideration, as indicated in the President's message on the State of the Union. The matter of the creation of an executive department of health with cabinet status may be deferred until after the Hoover Commis-

sion makes its report on streamlining the Executive Department. At the close of the hearings on S. 545 and S. 1320, the Senate Committee on Labor and Public Welfare will have to decide whether to report out either or both of the bills. If it does not take such action before the close of the session, the bills will be dead. The House has not indicated any action on H. R. 3548 (Dingell) the companion to S. 1320. S. 545 has no companion bill in the House.

The President's Budget Message

The 1949 budget suggests expenditures for social welfare, health and security estimated at \$2,028,102,127, including \$116,000,000 for financing proposed legislation. The estimate involves increases for public health and public assistance pro-

grams and initial cost of the proposed health insurance program. The recommendations for a health insurance program contemplate a total initial payroll tax of 0.5 of 1 per cent of the individuals' salaries up to \$4,800 a year, effective Jan. 1, 1949, to furnish a basis for establishing eligibility for benefits and to build up an operating reserve. Permanent rates, to make the program mainly self financing, would be set up in a year or two.

Included in the budget is an increase for education and general research which results mainly from the proposed grants by the federal government to states to aid elementary and secondary education and from the proposed establishment of a National Science Foundation. The budget estimates assume the creation of the National Science Foundation; passage of such legislation was again urged. For the hospital and medical care of the Veterans Administration \$615,000,000 is estimated. The operating expenses of this program will increase substantially because of the steady rise in patient load. The outpatient care program will cost slightly less than in the current year.

The President in his message stated that he intends shortly to discuss, in a special message to Congress, proposals that would have immediate fiscal effects on the following items: the extension coverage of old age and survivors' insurance; increase in individual benefits; provision for a national system of health insurance and improved services and facilities for public health and medical care, and extension of unemployment compensation pertaining to federal aid for public assistance so as to relate them to the financial resources and needs of each state.

Appointment of Dr. Magnuson as Veterans' Medical Chief Applauded

The appointment of Dr. Paul B. Magnuson of Chicago as medical chief of the Veterans Administration to succeed Dr. Paul R. Hawley has received favorable comment. Typical was that of George Beveridge in the *Washington Evening Star*: "A 63-year-old Chicago surgeon is visualizing a daring plan to make a Government hospitalization program the center of medical progress in this country. He is Dr. Paul B. Magnuson, whose selection as medical director of the Veterans' Administration gives reason for elation among the Nation's sick war veterans as well as its doctors." Dr. Magnuson places considerable stress on the hospital training program, which now has some two thousand young residents. Careful supervision is to be given to their training. The program has been extended through state and county medical societies permitting civilian physicians to take advantage of courses. The new director states: "Adequate and fast treatment of World War II veterans in hospitals and clinics now will save millions of dollars that otherwise will have to be poured into hospitals later. The American people are paying for this program. They should know what it can do. Then, they must make up their minds whether they want to support it."

Incidence of Chronic Diseases

Dr. P. S. Lawrence of the U. S. Public Health Service has just reported results of a study on the incidence rate of chronic disease requiring more or less regular care of a physician. The study shows that the rate starts to climb at the age of 45. The survey showed that at 25 years of age about 35 of every thousand persons have some chronic illness or major physical disability. Then a gradual increase occurs to a rate of about 100 cases per thousand at age 45. At age 60 there are some 250 chronically ill persons per thousand, increasing during the next 10 year age bracket to 400 per thousand. At 80 years of age, more than half of the group requires regular care of a physician, and the rate is more than 900 per thousand at age 90. Study of the figures also discloses that of every 1,000 persons who are well at 45 years of age, 100 during the subsequent five years will require medical attention for a chronic or major illness. A few will require almost constant medical care until death. The report shows that in nearly 25 per cent of the persons who are well at 60 years of age a chronic ailment will develop in the following five years. The survey showed that the total death rate for a twenty-five year period was about 178 fatalities per thousand, 196 among males and 158 among females. The study was based on a quarter of a century survey conducted among

the population of Hagerstown, Md. Health conditions of all persons of all ages among 2,000 white families were tabulated. The record was kept of what had happened to the group as a whole and to those in perfect health in 1923.

Negro Veterans' Hospital Authorized by House of Representatives

A bill authorizing a \$5,000,000 hospital for Negro veterans, to be erected at the birthplace of Booker T. Washington in Franklin County, Virginia, has been passed by the House of Representatives and sent to the Senate. Representative Edith Rogers, Republican of Massachusetts, chairman of the House Veterans Affairs Committee, said that the hospital would be of great benefit to Negro veterans, 50,000 of whom are in Virginia alone. Representative John Rankin, Democrat of Mississippi, supported passage of the bill to care for Negro veterans of not only Virginia but also West Virginia, eastern Tennessee and other nearby areas. A committee report on the bill stated that a hospital in Franklin County would be a "timely recognition" of the services rendered by Booker T. Washington, "one of the most outstanding leaders of the Negro race."

Red Cross Buys Forty-Three Thousand Transfusion Sets

The American Red Cross has bought about 43,000 blood transfusion recipient sets from surplus stocks of the War Assets Administration. The sets, built for wartime use in the field, cost the government 90 cents each and were sold to the Red Cross for 10 cents each. The apparatus was new and was examined and approved by the U. S. Pure Food and Drug Administration. Sets, sealed in metal tubes, consist of glass filter housing, metal filter, one 3½ foot (106.68 cm.) length of rubber tubing and one 18 gage, 1½ inch (3.81 cm.) airway cannula needle.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Donald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Philadelphia, Feb. 26. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Central Surgical Association, Chicago, Drake Hotel, Feb. 19-21. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 10-13. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

National Conference on Medical Service, Chicago, Palmer House, Feb. 8. Dr. Edward F. Sladek, 232 E. Front St., Traverse City, Mich., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, Feb. 23-26. Dr. Max M. Green, 1430 Tulane Ave., Room 105, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Los Angeles, Ambassador Hotel, Feb. 24-28. Dr. Carleton Mathewson Jr., Stanford Univ. Hospital, San Francisco, Secretary.

Tri-States Medical Association of the Carolinas and Virginia, Charleston, S. C., Fort Sumter Hotel, Feb. 9-10. Dr. James M. Northington, 306 N. Tryon St., Charlotte 2, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

THE PHYSICIAN'S FEDERAL INCOME TAX

Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association

Federal income taxpayers on a calendar year basis must on or before March 15 do two things: (1) they must file their final returns for the year 1947 and (2) they must file a declaration of estimated tax for 1948.

WHO MUST FILE RETURNS

A return must be filed by every citizen or resident of the United States whose total gross income in 1947 was \$500 or more. Joint returns may be filed by husband and wife if (1) they were married at the end of the year and (2) both were citizens or residents of the United States. Such a joint return may be filed even though one spouse has neither income nor deductions.

WHO MUST FILE DECLARATIONS OF ESTIMATES

In addition to filing the final return for 1947, certain taxpayers must file on or before March 15 a declaration of estimated tax for 1948. Such a declaration must be filed by a taxpayers if:

- (1) his gross income from wages or salary subject to withholding can reasonably be expected to exceed the sum of \$5,000 plus \$500 with respect to each exemption, except his own, or
- (2) his gross income which is not subject to withholding can reasonably be expected to exceed \$100 for 1948 and his gross income from all sources can reasonably be expected to be \$500 or more.

A taxpayer, if necessary, may file one or more amended declarations during 1948 but only one in each calendar quarter. The last such amended declaration must be filed on or before Jan. 15, 1949.

The estimated tax may be payable quarterly as it was in 1947, the final payment becoming due Jan. 15, 1949.

TAX RATES AND EXEMPTIONS

The normal tax rate remains at 3 per cent, but after the tentative tax is computed at this rate there is allowed a reduction of 5 per cent of the tax thus computed. The surtax rate begins at 17 per cent of the first \$2,000 of surtax net income. As with the normal tax, after the tentative surtax is computed a reduction of 5 per cent of it is permitted by the Revenue Act of 1945. These rates apply in connection with 1947 income. They must also be used in the declaration of estimated tax for 1948, unless rates are changed by Congress prior to March 15.

For both normal and surtax purposes, the exemptions are in the amount of \$500 each for the taxpayer, for his or her spouse and for each dependent whose gross income is under \$500.

The determination as to whether a taxpayer is single or married is made as of the last day of the taxable year. There is no status determination date for dependents, the test being whether the taxpayer furnished over half of the support.

GROSS AND ADJUSTED GROSS INCOMES

Gross Income.—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is on a cash receipts and disbursements basis, plus such money as he has received from investments and from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added

to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Tuition payments and subsistence allowances for veterans made under the G. I. Bill of Rights are not taxable income. Mustering out payments are likewise nontaxable.

Adjusted Gross Income.—Adjusted gross income is defined to mean gross income minus:

- (1) deductions attributable to a trade or business carried on by the taxpayer, if such trade or business does not consist of the performance of services by the taxpayer as an employee;
- (2) expenses of travel, meals and lodging while away from home, paid or incurred by the taxpayer in connection with the performance by him of services as an employee;
- (3) certain reimbursed expenses in connection with employment;
- (4) deductions attributable to property held for the production of rents or royalties;
- (5) depreciation or depletion allowed a life tenant of property or to an income beneficiary of property held in trust, and
- (6) losses from the sale or exchange of property.

The adjusted gross income is to be used as a basis to determine (1) the limitation on the deduction for charitable contributions (15 per cent of the adjusted gross income), (2) the amount of the deduction for medical expense (excess over 5 per cent of adjusted gross income), (3) the amount of the optional standard deduction the taxpayer may elect to take (10 per cent of adjusted gross income in certain income brackets), (4) exemptions in certain cases where joint returns are filed by husband and wife and (5) if the taxpayer may take advantage of the optional tax table devised for incomes under \$5,000.

OPTIONAL TAX TABLE

If a taxpayer has an adjusted gross income of less than \$5,000, he may if he so elects compute his tax by using the optional or alternative tax table. This table allows for the normal tax and surtax exemptions and for nonbusiness deductions approximating 10 per cent of the adjusted gross income. The election may be exercised irrespective of the source of the income. This table may not be used if the adjusted gross income of the taxpayer is \$5,000 or more, but in such cases an optional flat \$500 deduction may be claimed in lieu of nonbusiness deductions generally, such as charitable contributions, interest and taxes. Such a taxpayer may elect to exercise this option or he may itemize such deductions as in prior years. The taxpayer who reports an adjusted gross income of less than \$5,000 a year will not be allowed the standard deduction as a separate item. Its benefits may be obtained only by using the optional tax table, which, as already indicated, assumes that the user of the table is entitled to a deduction approximating 10 per cent of his adjusted gross income.

PHYSICIANS IN SERVICE

The fact that a physician is in service does not of itself excuse a failure to file a return or declaration. It is understood, however, that if because of the inaccessibility of the necessary

records a physician in service is unable to file a complete return he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following the procedure. At a later date, if that procedure is followed, a complete return must be filed and necessary adjustments in tax will be made. What has just been said relates to physicians in service who are stationed in this country.

If a physician in service is on duty outside the United States, no income tax return will become due, generally speaking, until the fifteenth day of the sixth month following the month in which the physician ceases, except by reason of death or incompetence, to be a member of the military forces on sea duty or in service outside the continental United States. The return must be filed not later than June 15, 1948.

The law provides a special exemption for members of the armed forces. For taxable years after 1942 and before the termination of the war, so much of the active service pay as does not exceed \$1,500, received as a commissioned officer or a commissioned warrant officer, is excluded from gross income. In addition the commissioned officer is entitled to the personal exemptions, credits and allowable deductions provided by law. For taxable years after 1940 and before the end of the war all the pay for active service received by a serviceman below the grade of commissioned officer or commissioned warrant officer is nontaxable. He too is entitled to the other exemptions, credits and deductions.

If ability to make payment is materially impaired by reason of service, deferment of the tax, without interest, until six months after active service terminates can be effected through the office of the collector of internal revenue, under section 513 of the Soldiers' and Sailors' Civil Relief Act. Furthermore, if it causes hardship to meet tax liability after termination of service, additional extension may be obtained under section 700 of that act, by application to the courts, for a period equal to the length of military service, subject to the requirement of periodic payment, with interest at 6 per cent.

The Revenue Act of 1945 grants further extension of time for payment, without interest, of any tax attributable to service pay for any taxable year beginning after Dec. 31, 1939 and before Jan. 1, 1947. The payment of the tax, if proper application is made, will be extended for thirty-six months, payable in twelve equal quarterly instalments. In the case of regular officers this extension operates only when the tax has been deferred by reason of sea or overseas duty. Application for the extension must be filed before the first instalment date which the law fixes as follows: If the release from active duty was prior to Dec. 1, 1945 the first instalment date was May 15, 1946; (2) if released on or after Dec. 1, 1945 the first instalment date was June 15, 1947 or the fifteenth day of the sixth month which begins after the date of release from active duty, whichever was earlier. A similar extension can be had in connection with the payment of the tax attributable to earned income of the years 1940 and 1941 which became due after entry into service. Earned income for this purpose cannot exceed \$14,000.

Any tax owed by any person who died while in active military or naval service of the United States or of any of the other united nations on or after Dec. 7, 1941 and before Jan. 1, 1948 will be canceled. Any tax for years prior to 1941 and before entry into service, including interest and penalties which are unpaid at the date of such death, will likewise be canceled. If the tax has been collected it will be refunded provided a claim for the refund is filed before Jan. 1, 1949. This tax forgiveness applies only to income taxes and not to estate tax.

The cost of equipment of an army officer or navy officer is deductible only to the extent that it is especially required for his profession and does not merely take the place of articles required in civilian life. The cost of uniforms is considered a personal expense and hence not deductible. The cost of gold braid and cap devices required by regulations of the Navy to

be worn on the clothing of a naval officer has been held to constitute an expense necessitated by reason of his profession as an officer and to be deductible as a business expense.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. As far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment, and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each individual case.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. An individual taxpayer can deduct such contributions only to the extent that they do not exceed 15 per cent of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but if they are passed on to the buyer the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise or stamp taxes are deductible only to the extent that they are attributable to business activities. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts expended for medical, dental and hospital care for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the adjusted gross income of the taxpayer but not in excess of \$2,500 in case of a taxpayer with more than one exemption, or \$1,250 in case of a taxpayer with only one exemption.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Science Foundation

A bill introduced by Representative Priest, Tennessee, H. R. 4852, proposes to enact a National Science Foundation Act which would establish a National Science Foundation as an independent agency of the government. This foundation will be authorized to foster and encourage a national policy for scientific research and scientific education, to grant scholarships and graduate fellowships in the mathematical, physical, medical, biologic, engineering and other sciences, to foster the interchange of scientific information among scientists in the United States and foreign countries and to correlate the foundation's scientific research programs with those undertaken by individuals and by public and private research groups. The bill with certain exceptions follows closely the legislation passed during the First Session of the Eightieth Congress and vetoed by the President.

It provides that there shall be a director of the foundation to be appointed by the President, by and with the advice and consent of the Senate. The vetoed bill provided that this director was to be appointed by the foundation. The present bill, too, omits any provision specifically authorizing the creation of special commissions on cancer research, on cardiac and intravascular diseases, poliomyelitis and other degenerative diseases. It provides for a number of special divisions of the foundation, including a Division of Medical Research.

With respect to patent rights, it provides that each contract or other arrangement relating to scientific research must contain provisions covering the disposition of inventions produced thereunder in a manner calculated to protect the public interest and the equities of the individual or organization with which the arrangement is made.

National Heart Institute

Two bills, H. R. 5087, introduced by Representative Keefe, Wisconsin, and H. R. 5159, introduced by Representative Smathers, Florida, proposed to enact a National Heart Act. There would be established in the United States Public Health Service a National Heart Institute to conduct research and control relating to diseases of the heart and circulation. It is contemplated that there will be created a National Heart Council, composed of the Surgeon General of the Public Health Service, or his representative, the Chief Medical Officer of the Veterans Administration, or his representative, the Surgeon General of the Army, or his representative, the Surgeon General of the Navy, or his representative, and twelve members appointed by the Surgeon General of the Public Health Service with the approval of the Federal Security Administration. Grants-in-aid to states and local governments for the establishment of local heart disease control programs will be authorized if this legislation is enacted.

Food, Drug and Cosmetics

Legislation proposing to give the Food and Drug Administration jurisdiction over foods, drugs, devices or cosmetics when held for sale, whether or not the first sale, after shipment in interstate commerce, has been passed by the House of Representatives.

Miscellaneous

A bill introduced, by request, by Senator Buck, Delaware, S. 2027, would amend the healing arts practice act of the District of Columbia so as specifically to authorize the issuance of licenses to applicants without examination who are certified as competent by a national examining board.

The construction of a Veterans Administration general medical and surgical hospital in Baltimore, Md., is contemplated by H. R. 4950, introduced by Representative Meade, Maryland.

A bill introduced by Representative Patterson, Connecticut, H. R. 4914, proposes to establish a presumption of service-connection for functional disorders of the nervous system and psychoses for certain veterans of World War II.

Senator Pepper, Florida, proposes by S. 1863 to amend the Internal Revenue Code to authorize the deduction of educational expenses of teachers in computing income taxes.

S. J. Res. 166, introduced by Senator Smith, New Jersey, for himself and Senator Fulbright, Arkansas; Senator Saltonstall, Massachusetts; Senator Bricker, Ohio; Senator Knowland, California; Senator Hatch, New Mexico; Senator Lodge, Massachusetts; Senator Thomas, Utah; Senator Ball, Minnesota; Senator O'Mahoney, Wyoming, and Senator Hill, Alabama, provides that any future payments by the republic of Finland on the principal or interest of its debt of World War I to the United States shall be used to provide educational and technical instruction and training in the United States and for citizens of Finland, the students to be selected, on nomination of the government of Finland, by the Board of Foreign Scholars.

Representative McCormack, Massachusetts, proposes by H. R. 5037 to exempt from the manufacturers' excise taxes articles sold to hospitals not organized for profit.

An expansion of the hospital facilities at the United States Veterans' Hospital at Muskogee, Okla., is to be authorized by H. R. 5070, introduced by Representative Stigler, Oklahoma. The bill would authorize an appropriation of \$500,000 for this purpose.

STATE LEGISLATION

Kentucky

Bills Introduced.—S. 62 and H. 89, relating to license taxes in certain cities in the state, propose to authorize the board of aldermen to provide for licensing any profession and for the using of any animal.

Massachusetts

Bills Introduced.—H. 703 proposes to authorize the establishment of a University of Massachusetts in Boston to furnish instruction, among other things, in medicine. H. 1156 proposes to entitle all persons within the state to be entitled to the full and equal accommodations of dispensaries, clinics, hospitals, and business or professional schools, without discrimination because of race, color, creed or national origin. H. 1224 proposes the establishment of a school of medicine as a part of the University of Massachusetts. H. 1227, relating to the purposes for which the school committee of the city of Boston may make appropriations, proposes to authorize appropriations for organizing and conducting physical training and exercises, athletics, games and the like under the control of the committee and further proposes to authorize the payment by insurance or otherwise of the reasonable hospital, medical and surgical expenses incurred by or in behalf of any student who sustains injuries while participating in any of the organized school athletics. H. 1347 proposes the creation of a Massachusetts state board of naturopathic examiners. Naturopathy is defined by the proposal as the prevention, diagnosis and treatment of human ailments and diseases by means of any one or more of the psychologic, physical or mechanical, chemical or material forces of nature, excluding drugs, surgery or other artificial measures. S. 162, relative to increasing the curriculum of the University of Massachusetts, proposes the establishment of a medical and dental school in Springfield.

Bill Passed.—H. 91 passed the house January 20. To amend the medical practice act, it proposes to provide for the revocation of the certificate of registration of any physician guilty of the use of narcotic drugs in any way other than for therapeutic purposes.

Mississippi

Bills Introduced.—H. 37 proposes that no license to marry shall be issued to a male or female applicant unless the applicant presents a medical certificate and laboratory report to the circuit clerk at the time of the application. The medical certificate shall be executed by an active licensed physician in Mississippi, or a physician licensed to practice in any or all of the other states in the United States or the District of Columbia, or by a commissioned medical officer on active duty in the armed forces of the United States, or by a medical officer of the United States Public Health Service. S. 63 proposes that the board of trustees of universities and colleges shall maintain the first two years of the four year medical school at Oxford, Miss., until such time as the legislature shall authorize the removal therefrom, and shall locate the remainder of the medical course in conjunction with a standardized and departmentalized hospital for teaching purposes of not less than three hundred fifty beds.

New York

Bills Introduced.—CCH A. RES. 43 proposes that the Congress of the United States be memorialized to appropriate the sum of \$100,000,000 to finance or subsidize a campaign to discover the cause of cancer and other kindred malignancies. A. 236, A. 373 and S. 293 propose the enactment of antidiscrimination laws. A. 348, to amend the education law, proposes the establishment of an Empire State University to be composed, among other things, of a school of medicine. A. 370, to amend the education law, proposes to require the board of education to provide adequate health services for pupils attending the public schools, such service to include the necessary facilities to afford adequate physical examinations, including roentgen examination of the chest of all pupils, annually. S. 171, to amend the law relating to prescriptions for somnifacient drugs, proposes to prohibit the refilling of prescriptions for a barbiturate or other hypnotic or somnifacient drug unless the prescription includes a statement by the prescriber that it may be refilled and specifies the minimum interval between fillings and the total number of refillings prescribed. No such prescription shall be refilled in any event later than three months after the original issuance thereof. S. 280, S. 283 and S. 370 are the same as S. 371, previously detailed (THE JOURNAL, p. 355, January 3). To amend the law relating to employment insurance, they propose to extend the term "total employment" to include unemployment caused by sickness or disability, which is certified by a physician or surgeon duly licensed to practice in the state of New York or in any other state, territory or possession of the United States. S. 392, to amend the unemployment insurance law, proposes to extend the coverage thereof to include employees of charitable, scientific, literary or educational organizations. S. 372, to amend the workmen's compensation law, proposes to allow an employee a reasonable fee for medical witnesses. S. 395, to amend the education law, proposes the creation of a board of examiners in ophthalmic dispensing. S. 463, to amend the judiciary law, proposes to exempt physical therapists and podiatrists from jury service. S. 475, to amend the workmen's compensation law, proposes to authorize injured claimants to have free choice of a duly authorized hospital. S. 491, to amend the vehicle and traffic law, proposes to require chauffeurs to obtain a certificate from a duly licensed physician attesting that the applicant has been examined and found mentally and physically competent at least once every three years. S. 492, to amend the vehicle and traffic law, proposes that the test of operators and chauffeurs shall include a test for color blindness and night driving tests.

Rhode Island

Bills Introduced.—H. 572 and S. 48, to amend the law relating to professional nursing, propose to add a few sections which would regulate the practice of practical nursing, a term which is not defined.

GOVERNMENT SERVICES

ARMY

ARMY TO TEST NEW DRUG AGAINST SCRUB TYPHUS IN MALAYA

The Army Medical Department soon will stage an extensive test of the efficacy of chloromycetin, the only drug thus far discovered which is as effective against certain rickettsial organisms as the sulfonamide drugs and penicillin are effective against bacteria. The test will be made in an effort to stop the spread of scrub typhus in the Far East. Dr. J. E. Smadel, director of virus research, Army Medical Center, and one of the discoverers of this substance, plans to fly to the Malay States early this spring to treat plantation workers among whom scrub typhus is making serious inroads. The carrier of the infection is a mite which is probably spread by rodents. During the war many plantations in Malaya were allowed to go back to brush. This resulted in an increase of infested rodents. Workers who clear the plantations have suffered a heavy mortality rate.

The early experiments at the Army Medical Research and Graduate School showed that chloromycetin was effective against the organism responsible for scrub typhus (rickettsial tsutsugamushi). This organism is related to the organism responsible for epidemic typhus, but typhus vaccine has proved useless as protection against scrub typhus. The new drug showed considerable potency against both typhus and scrub typhus organisms in experimental infections of incubated eggs and in animals. It also proved effective against several other diseases due to rickettsia. Experience has shown, however, that laboratory results do not always work out in the field. Dr. Smadel has just returned to Washington from Mexico, D. F., Mexico, where the new drug was tested against typhus. The Army is not ready to announce the results. The proposed attack on scrub typhus is considered of great importance, since this disease has proved difficult to treat in any known way.

The outlook is promising, according to the Surgeon General. At least a start has been made on specific drug treatment of the large class of rickettsial diseases which are responsible for some of the most devastating scourges of the human race. It has been found to be mildly effective against psittacosis. However, the psittacosis organism is one of the largest of the viruses and just falls short of being classified as a rickettsia.

Scrub typhus was a major problem in the Pacific area during the war. Efforts to produce a vaccine against it cost the lives of three American and several British workers. Nothing was accomplished until the war was nearly over. A vaccine finally was prepared from the macerated lungs and spleens of infected rodents, but when this was given actual field tests it was found to be ineffective.

CONSULTANTS ASSIST IN NEW OVERSEAS PROGRAM

The first two civilian Army medical consultants to participate in the new overseas advanced professional training program departed for Europe about January 20 for a month's tour of hospitals in the American-occupied zone of Germany. The two consultants were Dr. George Finney, surgeon, Johns Hopkins University School of Medicine, Baltimore, and Dr. Walter Martin, internist, in private practice in Norfolk, Va. Completing the team was Col. Beverly Smith, M. C., chief, psychiatric service, Walter Reed General Hospital. The departure of this group marks the inauguration of one aspect of a plan to achieve the highest possible standards of medical care, professional training and career advancement of the professional personnel of the Medical Department. It is planned to send overseas in connection with this program two consultants and one medical corps officer each month. The mission will be, first, to study and report on means of improving the care of hospital patients and, second, to act as instructors in specialized advanced training of medical officers.

The Surgeon General recently asked each of the six hundred and seven civilian specialist consultants of the Medical Department if they could volunteer for overseas assignment under this plan, and of the two hundred and sixty-nine who had replied to January 13, seventy-six said that they would be available this year, sixty-one replied that they would try to join in the program and one hundred and thirty-two, less than one-half, stated that professional commitments would prevent their participation.

MEDICAL MEETING IN KOREA

About eighty-five officers including nurses, dietitians, and medical service corps personnel attended the monthly meeting of Army Medical Officers stationed in Korea at the 71st Station Hospital, APO 6, January 14. Major Frank A. Neuman of the 6th Infantry Division read a paper on "The Cholera Epidemic in Korea in 1946," which was discussed by Capt. Ernst Kopp. Both men played an important part in the control of the epidemic. About 15,000 cases with 10,000 deaths occurred in 1946, while only 16 cases with 10 deaths occurred in 1947. All cases were among Koreans. Dr. Clarence Bigger, adviser, Department of Public Health and Welfare, U. S. Army Military Government in Korea, who has spent many years there as a medical missionary, reviewed his experience during similar epidemics as well as control measures used by the Japanese during their occupation of Korea. Capt. Arnold G. Blumberg, on request, again presented his paper on rheumatic fever, as the incidence of this disease may be expected to increase at this time of year. Captains Howard N. Baier and Arthur H. Keeney, both of the 71st Station Hospital, discussed diseases of the upper part of the respiratory tract. Visiting officers, who arrived in Pusan at 4 a. m. January 14, were transported to the station hospital, where breakfast was served. The business meeting was in charge of Col. Charles P. Ward, surgeon, XXIV Corps. Among others present was Lieut. Col. Warner F. Bower, surgical consultant, who took part in the discussions.

OFFICER SELECTION BOARDS TO MEET

The Department of the Army announces that selection boards to recommend officers for promotion to regular Army grades from captain to lieutenant colonel will meet in Washington during the spring. The first board to study qualifications of majors for promotion to lieutenant colonels will meet early in February. It is expected that medical corps lieutenant colonels will be chosen from all lower grade officers with over sixteen years' service, and majors from those officers with over ten years' service on July 1. The Army emphasizes that under the Officer Personnel Law of 1947 officers not recommended for promotion by this year's board will not be considered to have been "passed over." Excepting only the initial promotion, the law provides that after an officer has been "passed over" for promotion on two consecutive occasions he will be removed from the service.

ARMY MEDICAL CORPS TEACHING BASIC SCIENCES

The Surgeon General has announced the opening of an experimental course in basic science for the Army's residents in training. Twenty-five selected trainees are attending the sixteen week postgraduate course at the Army Medical Center, Walter Reed General Hospital. Classes in laboratory and clinical work are being taught by men from leading hospitals and medical schools. Major General Bliss, the Surgeon General, commented: "Unless we make our standards as high as anywhere we cannot

expect to attract men to the Medical Corps." He explained that the army now has three hundred and seventy men in residency training. Dr. Irvine H. Page, director of research, Cleveland Clinic, was a speaker, and present for the opening were Col. Rufus L. Holt, commandant, Army Medical Department Research and Graduate School, and Col. Walter H. Moursund, director of training, Army Medical Center, who helped organize the course.

ATOMIC BOMB CHIEF PROMOTED

The President has sent to the Senate the name of Major Gen. Leslie R. Groves for promotion to the rank of lieutenant general under the new officer personnel law of 1947. General Groves is widely known for his work as head of the Manhattan Project, under which research, design, construction and operation of facilities for the atom bomb were developed. General Groves now is assistant to the chief of engineers, Army member of the military liaison to the Atomic Energy Commission and chief of the Armed Forces Special Weapons project.

COURSE IN ATOMIC MEDICINE

More than twenty medical schools throughout the country have accepted invitations to send representatives to the five day intensive course on the medical aspects of atomic explosion which began at the Army Medical Center, Washington, D. C., on January 12. These courses have been given once a month since last October but were opened to representatives of medical schools only since December. Although to date four hundred and thirty doctors have taken this special instruction, the enrollment for the February course, the last in the series, is expected to increase that number considerably. Others taking the course are drawn chiefly from the military and other federal agencies.

LETTERMAN EXHIBIT

Jonathan Letterman, the medical officer who revolutionized the system of care of the wounded in battle, is the subject of an exhibit at the Army Medical Library in the series Famous Men of Army Medicine. Letterman is considered by many to be the greatest name in military medicine. His plan—the ambu-

lance corps, the method of supply and the field hospital system—was thoroughly tested and proved in the Civil War, when he was medical director of the Army of the Potomac. It has since then been the model of armies all over the world and remained the basic structure of military medical care through World War II. Interesting items are Letterman's book, "Medical Recollections of the Army of the Potomac," published in New York in 1866, and charts showing the modern adaptations of his plan on D-Day and on VE-Day, "Evacuation in the European Theater of Operations."

ARMY MEDICAL LIBRARY NEEDS HELP

There are now seventeen vacancies on the staff of the Army Medical Library, as the result of the recent increase in its personnel ceilings. Of this number, ten positions are allocated to the professional grades, ranging from P-1 through P-3 (\$2,644.80 to \$4,149.60). While all positions in the Army Medical Library are under civil service, because of the unusual language difficulties encountered in this library the Civil Service Commission has authorized direct recruiting to fill certain P-2 and P-3 vacancies in the Catalog Division. The library will be glad to receive applications on standard form 57 from interested librarians.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel John A. Grove

The Bronze Star Medal has been awarded to Lieut. Col. John A. Grove, M. C., A. U. S., now of Newton, Kan. The citation read in part as follows: For meritorious service in connection with military operations, as surgical coordinator and orthopedic consultant, 15th Hospital Center, from June 6, 1944 to May 8, 1945. Lieutenant Colonel Grove, with professional brilliance and remarkable devotion to duty, assisted in the development of "specialty" general hospitals which rendered invaluable support to the Medical Department in achievement of its overseas mission. Through his capacity for selection of personnel and his genius for research in specialized fields, the care of wounded men in the hospitals under him was lifted to a peak of excellence. Dr. Grove graduated from Northwestern University Medical School in 1937 and entered military service in July 1942.

NAVY

RESERVE CONSULTANTS BOARD

At the annual meeting of the Reserve Consultants Board to the Bureau of Medicine and Surgery at Bethesda, Md., January 9, the Surgeon General, Rear Adm. Clifford A. Swanson, spoke on matters pertaining to legislation; Capt. W. A. Wylie (MC), chief, Naval Reserve Unit of the Bureau, on organization of units of the Naval Reserve, and Capt. O. L. Burton (MC), chief, Division of Preventive Medicine in the bureau, discussed preventive medicine as it relates to the program of the medical department. The Reserve Board, which is composed of civilian specialists in various fields of medicine, confers with the bureau concerning its graduate medical training program and specialty board requirements of medical officers. In addition to the board members and medical officers of the Navy, the following civilian guests attended the conference: Drs. H. P. Saunders and W. A. Bloedorn, dean, George Washington University Medical School, Washington, D. C.

NAVY AWARDS AND COMMENDATIONS

Dr. Morris Fishbein

President Truman has awarded the Certificate of Merit to Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, in recognition of his "outstanding efforts as Chairman of the Committee on Information of the National Research Council, which proved to be an invaluable contribution to the war effort of the United States." In notifying Dr. Fishbein of the honor, Comdr. G. E. Pierce of the U. S. Navy, secretary of the Civilian Awards

Board in Washington, D. C., said that the award is given to "civilians for outstanding fidelity and meritorious conduct which aided in the war effort against common enemies of the United States and its allies in World War II." The certificate was presented January 23 in a brief ceremony at the American Medical Association headquarters by Rear Admiral J. Cary Jones, Commandant of the Ninth Naval District, Great Lakes, Ill.

PERSONALS

Rear Admiral C. A. Swanson, Surgeon General of the Navy, left Washington, D. C., on January 29 to visit naval medical activities in Pensacola, Jacksonville and Key West, Fla. Admiral Swanson spoke on medical and nutritional conditions in Europe and the Near East at each of the naval medical activities.

Admiral Swanson reviewed the world's medical and public health situation in an interview broadcast on the "Farmer from Washington" program from Arlington, Va., January 25. He also addressed the faculty and student body of the University of Virginia School of Medicine at Charlottesville January 16 on preventive medicine and the need for doctors in the field.

Rear Adm. Lamont Pugh (MC), assistant chief, Bureau of Medicine and Surgery, represented the bureau at the January lecture in the Army Medical Corps series at Walter Reed General Hospital. Admiral Pugh spoke on the need for coordination of military and civilian medical services. The guest lecturer was Dr. Frank Lahey, Boston, whose subject was "Thyroid Diseases and Antithyroid Agents."

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Appoint New Professors.—Edward L. Tatum, Ph.D., professor of microbiology at the Institute of Microbiology, Yale University, New Haven, Conn., has been appointed professor of biology at Stanford University, effective September 1948. A graduate of the University of Wisconsin, 1935, Dr. Tatum was a research associate and later an assistant professor of biology at Stanford from 1937 to 1945, when he accepted an associate professorship at Yale.

Dr. John A. Luetscher Jr., assistant professor of medicine at Johns Hopkins University, Baltimore, will join the faculty in the fall as associate professor of medicine. He received his M.D. degree from Johns Hopkins University in 1937 and has been on the medical school's faculty since 1940.

CONNECTICUT

Conferences on Psychiatry.—The Institute of Living, devoted to the treatment of nervous and mental diseases, on January 14 inaugurated its fourteenth annual series of conferences on the progress of psychiatry. The remaining lectures are as follows:

February 18, Dr. William Sargent, London, England, Observations on Abreactions with Drugs.

February 25, Dr. Franz G. Alexander, Chicago, What Is a Psychoneurosis?

March 3, Dr. Henry W. Brosin, Chicago, Clinical Aspects of Rorschach Testing.

March 10, Dr. A. Warren Stearns, Boston, The Milieu in Which the Psychiatric Case Swims.

DISTRICT OF COLUMBIA

The Kellogg Medical Lectures.—The George Washington University School of Medicine, Washington, D. C., is presenting a series of eighteen evening lectures for physicians of the Washington area from January through April. The series is known as the Kellogg Medical Lectures in recognition of grants received for graduate medical education from the W. K. Kellogg Foundation of Battle Creek, Mich. Remaining lectures include:

February 10, Dr. Richard L. Varco, Minneapolis, Preoperative and Postoperative Care in Elective Abdominal Surgery.

February 17, Dr. Douglas A. Thom, Boston, Child Guidance.

February 19, Fred W. Rankin, Sc.D., Louisville, Ky., Carcinoma of the Colon and Rectum.

February 24, Dr. Nolan D. C. Lewis, New York, Psychotherapy for the General Physician.

February 26, Dr. Robert L. Patterson, Pittsburgh, Use of Blood Transfusions; Organization and Operation of Blood Banks.

March 2, Dr. Everts A. Graham, St. Louis, Problems Confronting the Surgeon.

March 4, Drs. James L. Pool and Israel S. Wechsler, New York, Conference on the Paralyzed Patient.

March 9, Dr. Herman E. Hilleboe, Albany, N. Y., The Minimal Tuberculosis Lesion.

March 11, Dr. Edwin C. Hamblen, Durham, N. C., Human Infertility.

March 16, Dr. Thomas Francis Jr., Ann Arbor, Mich., Prevention of Influenza.

March 18, Dr. Nicholson J. Eastman, Baltimore, Obstetric Factors in Infant Survival; Dr. Priscilla White, Boston, Diabetes in Pregnancy.

March 23, Problems in Endocrine Therapy (Panel).

March 25, Parent-Newborn Adaptation (Panel).

March 30, Dr. Lewis Dexter, Boston, Curable Heart Disease.

April 6, Dr. Paul D. White, Boston, Prevention of Heart Disease.

April 13, Dr. Julian M. Ruffin, Durham, N. C., Status of Vagotomy in the Treatment of Peptic Ulcer.

ILLINOIS

Lectures for County Societies.—The Scientific Service Committee of the Illinois State Medical Society has arranged the following lectures for county medical societies: La Salle County, in La Salle, February 12, Dr. John M. Huffman, Chicago, "Diagnosis and Treatment of Early Carcinoma of the Cervix"; Will-Grundy County, in Joliet, February 12, Dr. Chester Coggeshall, Chicago, "Recent Advances in Diabetes," and February 26, Dr. Emmet B. Bay, Chicago, "Drug Administration in Heart Disease"; Logan County, in Lincoln, February 19, Dr. Winston H. Tucker, Evanston, "Fluorine and Dental Caries." The Educational Committee of the state medical society has arranged a lecture by Dr. Pliny R. Blodgett, Chicago Heights, for February 18 at the Forest Ridge Woman's Club on "Blood Pressure"; another by Dr. George H. Rezek, Chicago,

at the Belmont's Women's Club, Chicago, February 18 on "Facing the Forties," and one by Dr. Franklin R. Fitch, Chicago, for February 23 at the South Edgebrook Woman's Club in Chicago, on "Venereal Disease as a Public Health Problem."

Chicago

National Heart Week Program.—The Chicago Heart Association is sponsoring its National Heart Week Dinner February 10 in the Crystal Room, Union League Club, at 6 p. m. Dr. Morris Fishbein, Editor, THE JOURNAL, will act as toastmaster. Dr. Howard A. Rusk, New York, will speak on "Rehabilitation and the Heart"; Dr. Wingate M. Johnson, Winston-Salem, N. C., "The Years After Forty," and Dr. Arlie R. Barnes, Rochester, Minn., president of the American Heart Association, "The Public's Stake in the Problem of Heart Disease." Demonstrations and exhibits may be seen before dinner and after the program. The clinical section of the Chicago Heart Association will meet February 12 from 10 a. m. to noon in the auditorium, Sprague Home, School of Nursing, Presbyterian Hospital. Among the subjects on the program are nutritional considerations in the long range care of coronary thrombosis, management of chronic cardiac decompensation, physiologic methods in the diagnosis of congenital heart disease and unipolar electrocardiographic study. All physicians are invited to this meeting.

Annual Four Day Clinical Conference.—All physicians are invited to attend the Annual Clinical Conference of the Chicago Medical Society at the Palmer House, Chicago, March 2-5. The program has been planned to appeal to both general practitioner and specialist. Scientific and technical exhibits will be presented. The program is as follows:

TUESDAY

Tinsley R. Harrison, Dallas, Texas, Clinical Recognition of the Arrhythmias.

John D. Camp, Rochester, Minn., Roentgenologic Aspects of Malacic Diseases of Bone.

Edwin P. Lehman, Charlottesville, Va., Clinical Diagnosis of Infection Following Chemotherapy and Antibiotics.

Waltman Walters, Rochester, Minn., Present Status of Surgical Intervention in Peptic Ulcer.

Axel N. Arneson, St. Louis, Ratiocination in the Treatment of Cancer of the Cervix Uteri.

Francis M. Rackemann, Boston, The Doctor and the Patient with Asthma.

Franklin G. Ebaugh, Denver, Anxiety Syndromes in Clinical Medicine.

Chester M. Jones, Boston, Diagnostic and Therapeutic Value of Liver Function Tests.

George G. Smith, Brookline, Mass., Treatment of Prostatic Carcinoma.

WEDNESDAY

Harold C. Lueth, Omaha, Neb., Clinical Considerations in the Treatment of Bright's Disease.

Claude F. Dixon, Rochester, Minn., Safety Factors in Surgery of the Colon.

George M. Piersol, Philadelphia, Possibilities of Physical Medicine from the Standpoint of the Internist.

John S. L. Browne, Montreal, Canada, Response of the Adrenal Cortex to Disease and Injury.

William B. Castle, Boston, Differential Diagnosis of Splenomegaly.

Earl T. Engle, New York, Diagnosis and Treatment of Male Sterility.

R. Arnold Griswold, Louisville, Ky., Physiologic Changes Resulting from Vagotomy for Peptic Ulcer.

William S. Middleton, Madison, Wis., Rickettsial Infections in the United States.

Roscoe L. Sensenich, South Bend, Ind., President-Elect of the American Medical Association, General Management of Hypertension.

THURSDAY

Paul C. Colonna, Philadelphia, Diagnosis of Lesions in the Knee Joint.

Otto H. Schwarz, St. Louis, Chronic Subinvolution of the Uterus, Its Pathology and Clinical Significance.

Kenneth E. Appel, Philadelphia, Psychoanalytic Perspectives in Medicine.

Cameron Haight, Ann Arbor, Mich., Surgical Treatment of Mediastinal Tumors.

Clement A. Smith, Boston, Physiologic Advantages and Disadvantages of Newborn Patients.

John M. Adams, Minneapolis, Primary Respiratory Disease, Pathogenesis and Prevention.

E. Cowles Andrus, Baltimore, Factors in the Prognosis of Disease of Coronary Arteries.

James S. Speed, Memphis, Tenn., Treatment of Difficult Nonunions of the Long Bones.

Panel on Obstetrics.

FRIDAY

Carl W. Laymon, Minneapolis, Cancer of the Skin.

Herbert F. Traut, San Francisco, Functional Uterine Bleeding.

William F. Holbrook, Tucson, Ariz., Rheumatic Fever.

Alton Ochsner, New Orleans, Bronchogenic Carcinoma.

Francis W. Lynch, St. Paul, Current Views on the Treatment of Syphilis.

Charles C. Higgins, Cleveland, Management of Patients with Renal Lithiasis.

Francis E. LeJeune, New Orleans, Treatment of Early Carcinoma of the Larynx.

William E. Grove, Milwaukee, Wis., Craniocerebral Post-Traumatic Syndrome, A Practical Consideration.

William L. Bradford, Rochester, N. Y., Streptomycin Therapy. Clinicopathologic Conference.

INDIANA

Indianapolis Society Offers Aid to Prosecutor.—The Indianapolis Medical Society, in a letter to Prosecutor Judson Stark, has offered its assistance in the prosecution of Dr. Frederick E. Crum, Indianapolis, charged with performing an abortion on a young woman who later died. The physician has been arrested twice before on abortion charges but never has been convicted. The physician, 63 years of age, has been cited to appear before the state medical registration board to answer charges of "gross immorality." Dr. Crum is now free under \$2,000 bond.

Drs. Kaadt and Smith Lose Licenses.—The Indiana Supreme Court has handed down a decision declaring that the State Board of Medical Registration and Examination was acting within its authority in revoking the medical practice license of Dr. Peter S. Kaadt, South Whitley, a graduate of Rush Medical College, Chicago, 1895, on the grounds of "gross immorality." Dr. Peter S. Kaadt and his brother, Dr. Charles F. Kaadt, were accused of selling "worthless diabetes cures" at their sanatorium. Dr. Charles F. Kaadt, a graduate of Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902, surrendered his license without a hearing. The Indianapolis Better Business Bureau brought charges against the Drs. Kaadt.

Dr. George F. Smith, formerly of Terre Haute, has surrendered his license to practice medicine in Indiana. He was charged by the Indianapolis Better Business Bureau with claiming "absolute and complete cures" for cancer, diabetes, syphilis and other diseases. Dr. Smith, a graduate of Washington University School of Medicine, St. Louis, 1910, denied the charges in an appearance before the State Board of Medical Registration and Examination but agreed to cancellation of his license. He told the board he is now practicing in Chicago.

KANSAS

Red Cross Opens Blood Collecting Center.—The Sedgwick County (Wichita) unit of the national peacetime blood collection program of the American Red Cross was opened formally January 16 by Basil O'Connor, chairman. Residents of the county donated 4,634 pints of blood to the center, and women workers contributed 15,000 hours of work during the preceding week. Other officials of the national office attended the ceremonies.

MARYLAND

Outbreak in Baltimore of Grain Itch.—The Baltimore City Health Department's Division of Industrial Hygiene recently aided in diagnosing a peculiar rash that appeared among 12 employees of a local broom factory. The mite which caused the rash, identified as *Pediculoides*, and the *Angoumois* grain moth *Sitotroga cerealella*, which acts as one of the normal hosts of the mite, were found. Nine days after the first call for aid the plant was being sprayed with piperonyl butoxide and the outbreak was brought under final control. It is thought that the broom corn may in this instance have become infested in a freight car previously used to transport grain, for no such difficulty had been experienced in the factory from shipments brought by truck. Eight other broom factories in the city, employing about two hundred workers, were visited and gave no history of grain itch. In its sixty years' existence employees of the affected plant had had no similar experience.

NEW YORK

Tuberculosis Society Meetings.—The annual conference of the New York Tuberculosis and Health Association will be held March 9 at the Hotel Pennsylvania, New York. Authorities on tuberculosis, social hygiene and health education will present papers. The Tuberculosis Sanatorium Conference of Metropolitan New York will meet simultaneously.

Graduate Instruction at Port Jefferson, Watertown and Liberty.—The Medical Society of the State of New York in cooperation with the state department of health has arranged the following graduate programs: The Jefferson County Medical Society will hear Dr. Gray H. Twombly, New York, Thursday, February 12, at the Hotel Woodruff, Watertown, at 8 p.m. speaking on "Recognition and Treatment of Pelvic Cancer." A teaching day on kidney disease has been arranged for the staff of the John T. Mather Memorial Hospital, Port Jefferson, on February 19 beginning at 11:30 a.m. Dr. Louis F. Bishop Jr., New York, will speak on "Hypertension and Hypertensive Renal Disease;" Dr. Edward C. Coats, New York, on "Suppurative and Calculous Diseases of the Kidneys," and Dr. William Goldring, New York, on "Clinical Aspects of Glomerulonephritis." Dr. Frederick N. Marty, Syracuse, will address the Sullivan

County Medical Society February 25 at 8:30 p.m. at the Lenape Hotel, Liberty, on "Plasma Therapy and Whole Blood Transfusion."

New York City

Fifth Harvey Lecture.—Hermann J. Muller, Sc.D., professor of zoology, Indiana University, Bloomington, will deliver the fifth Harvey Lecture of the current series at the New York Academy of Medicine February 19 on "Evidence of the Precision of Genetic Adaptation."

Research on Epilepsy.—An anonymous gift of \$5,000 for research in epilepsy has been received at the Columbia University College of Physicians and Surgeons from a grateful father whose epileptic son regained his health. The money will be used to continue research in the Neurological Institute and the Baird Foundation Clinic.

Regulation of Coin-Operated Washing Machines.—The estimated twenty thousand coin-operated washing machines in apartment houses in the city will be regulated by the Board of Health after March 1 to enforce sanitary regulations concerning hot water and drainage. According to the *New York Times*, 90 per cent of these machines are owned not by the landlords but by operating companies. Owners will be responsible for adequate supplies of hot water. The sanitary code was amended to require water to be heated to 140 F. (60 C.) rather than to the present 200 F. (94 C.). At the same meeting the health authorities tightened the regulations concerning commercial laundries and hand and diaper laundries.

Savings Banks Endow Fellowship.—An endowed fellowship fund for medical research honoring the memory of the late Philip A. Benson, New York, has been established at the Long Island College of Medicine. Income from the fellowship of \$34,200 will be awarded on an annual basis and will defray, in part, compensation of a man or woman selected to do investigative work in one of the college's basic science or clinical departments. Funds to support this project were subscribed by the savings banks of the state and other interested friends and associates. Mr. Benson, who for many years was president of the Dime Savings Bank, had served as a trustee of the Long Island College of Medicine for twelve years and as chairman of its finance committee.

MICHIGAN

February Is Immunization Month in Michigan.—Local health departments and medical societies, the Michigan State Medical Society and the state department of health in February opened a campaign of immunization designed to reach every child in the state. The campaign will include the education of parents in the necessity of protection. Each county has made its own plans with the local health department coordinating and, where necessary, supplementing the work of practicing physicians of the area. No more than half a dozen counties in the state are adequately immunized to prevent an epidemic of diphtheria, according to the state health department, and whooping cough is appearing at a rate of more than 200 cases a week. The practicing physicians and local health departments will give the vaccines and toxoids, prepared by the state department of health, to every child whose parents wish him to have them without regard to whether the parents can pay for the treatment.

MISSOURI

Dr. Seelig Honored.—Dr. Major G. Seelig, for many years on the staff of the Barnard Free Skin and Cancer Hospital, St. Louis, was recently guest of honor at a dinner given by members of the staff and board members at Barnard. Dr. Seelig, now aged 73, is retiring and expects to make his future home in California.

PENNSYLVANIA

State Society Establishes the Benjamin Rush Awards.—The Pennsylvanian and the nonmedical lay organization which make the greatest contributions to the health of the people of the state will be presented the Benjamin Rush Award, an honor to be conferred each year by the Medical Society of the State of Pennsylvania. Service may have been made through study, research or other methods which have benefited the health of the general public of the state. Names of candidates for the awards will be received before March 31 by the board of trustees of the medical society from the county medical societies. This year's awards will be made at the centennial celebration in Philadelphia in October. Named after Benjamin Rush, one of Pennsylvania's leading medical men, surgeon-general in the Continental Army and signer of the Declaration of Independence, the award will be in the form of a bronze plaque containing a bas-relief of Dr. Rush.

Philadelphia

Blood Donor Center Near Completion.—The new \$50,000 Blood Donor Center, under construction at Jefferson Medical College and Hospital, is nearing completion. The new center will be integrated with Jefferson's blood-transfusion-plasma unit, which is under the direction of Dr. Lowell A. Erf.

Annual Fraternity Lecture.—The Phi Delta Epsilon annual lectureship at Jefferson Medical College was delivered by Dr. Harry Goldblatt, Los Angeles, on January 13 in the college assembly hall, on "The Renal Origin of Hypertension." Before the lecture a banquet was held at the Warwick Hotel in honor of Dr. Goldblatt.

PUERTO RICO

Group Arrives to Survey Medical Needs.—For the purpose of conducting a two week survey of medical needs of Puerto Rico and the Virgin Islands, at the invitation of Gov. Jesus T. Piñero, and with the approval of Secretary of the Interior Julius Krug, a group of members of the American Medical Association arrived in San Juan January 20, headed by Dr. Ernest E. Irons, Chicago, Secretary of the Board of Trustees of the American Medical Association. Other members of the mission are Dr. William L. Benedict, eye specialist of the Mayo Clinic, Rochester, Minn.; Dr. George M. Saunders, epidemiologist, Washington University, St. Louis; Dr. Edgar C. Person, surgeon of Cornell University, New York; Dr. John H. Willard, gastrointestinal specialist of Philadelphia; Dr. John H. Youmans, tuberculosis and nutrition specialist, University of Illinois School of Medicine; Dr. Heyworth N. Sanford, pediatric specialist, Presbyterian Hospital, Chicago; Dr. James B. McLester, tuberculosis and nutrition specialist, Birmingham, Ala.; Dr. William A. Morgan, who acted as coordinator for the American Medical Association and the United States Department of the Interior; Miss Edna Newman, nurse of Cook County Hospital, Chicago; Miss Catherine Sandford, Mrs. Ernest E. Irons, Spencer Irons, Mary Hill, William Morgan and Elizabeth Morgan. A special program consisting of lectures, round tables on various topics, visits to hospitals and other institutions was prepared by the local branch of the American Medical Association, under the direction of Dr. Juan A. Pons, commissioner of health of Puerto Rico, for the visiting physicians and specialists. After visiting St. Thomas, Virgin Islands, and Ciudad Trujillo, Dominican Republic, the group will return to New York via Pan American plane.

GENERAL

"If Your Child Stutters."—A leaflet for distribution to parents of stuttering children has been prepared as an initial step to eliminate sources of tension in the home. Physicians may obtain copies of the leaflet by writing to the Speech Information Bureau, National Hospital for Speech Disorders, 61 Irving Place, New York 3.

Electroencephalographers Meeting.—The Eastern Association of Electroencephalographers will meet at the Montreal Neurological Institute, Montreal, Canada, February 27-29. Among the subjects for discussion are "Operation for Focal Epilepsy with Electroencephalograms," "Electroencephalographic Findings in Patients with Brain Tumors" and "Brain Potassium in Relation to Behavior."

China Honors Missionary Doctor.—In tribute to the memory of Dr. Lee S. Huizenga, missionary physician in Shanghai who aided China in her fight against leprosy and tuberculosis, China's first national tuberculosis stamp is appearing. Dr. Huizenga founded China's two largest tuberculosis sanatoriums, both in Shanghai. He died July 16, 1945 after two and one-half years in a Japanese prison camp.

Hospitals and Homes Convention.—The annual meeting of the Board of Hospitals and Homes of the Methodist Church and the annual convention of the National Association of Methodist Hospitals and Homes will be held in Cincinnati February 17-19. Delegates will include hospitals and home administrators, chairmen of conference boards of hospitals and homes, members of boards of trustees of hospitals and homes, presidents of women's auxiliaries, chaplains and religious directors.

Scholarship for Training Hard of Hearing Teacher.—The American Hearing Society, through the Kenfield Memorial Fund, is offering a \$100 scholarship to any prospective hard of hearing teacher of lip reading to hard of hearing adults who lives in the United States and who can meet the requirements, bachelor's degree or equivalent and professional training in lip reading. The scholarship must be used within one year from granting of the award, and applications must be filed between March 1 and May 1, 1948 with Miss Rose V. Feilbach, 2431 14th Street N.W., Washington 9, D. C.

Poliomyelitis Exhibits.—Scientific exhibits which graphically depict data on poliomyelitis are available for annual meetings of state and regional medical associations. Prepared by the National Foundation for Infantile Paralysis, the exhibits cover diagnostic criteria, technic of muscle testing, histopathology and syndromes of bulbar poliomyelitis as well as results of scientific research on virus characteristics, role of flies and sewage and a working hypothesis of transmission during epidemics. Information may be had by writing to the Director of Scientific Information, National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

Schering Award Winners.—Paul J. Kopsch, Richmond Hill, Long Island, N. Y., a senior medical student at the Long Island College of Medicine, is the recipient of the Schering Award for 1947 for his paper on "The Clinical Use of Androgens in the Female." He received the first prize of \$500. The second prize of \$300 was awarded to Robert C. Foreman, Western Reserve Medical School, Cleveland, and the third prize of \$200 to Dr. Bernard L. Rosenberg, recently graduated from Georgetown University Medical School, Washington, D. C. Forty-three contestants received honorable mention. The Schering Award is given annually for the best manuscripts prepared on a designated phase of endocrinology. Medical students of the United States and Canada are eligible for the contest.

Postdoctorate Research Fellowships.—The Yale University School of Medicine, New Haven, announces that applications are now being accepted for postdoctorate research fellowships for 1948-1949. These are the Alexander Brown Cox Memorial Fellowships in the Biological Sciences, established in 1927; and the James Hudson Brown Memorial Fellowships, established in 1946 and available for promising applicants qualified to undertake research in the medical sciences, including clinical medicine and public health. The fellowships are open to graduates who hold the Ph.D. or M.D. degree and are awarded for one year but may be renewed. The annual stipend, usually from \$2,500 to \$3,500, is determined by individual circumstances. An additional sum may be assigned to the department to defray in part the cost of the proposed investigation. The closing date for applications is March 1. Information may be secured from Dr. C. N. H. Long, Dean of the Yale University School of Medicine, 333 Cedar Street, New Haven 11, Conn.

FOREIGN

Harofé Haivri, The Hebrew Medical Journal.—The fall issue of *Harofé Haivri*, or *Hebrew Medical Journal*, volume 2, 1947, contains a section dealing with health in Palestine. Dr. L. Olitzki of the Hebrew University writes on the "Contribution of Bacteriologists for the Control of Infectious Diseases in Palestine"; Dr. A. Wolowelsky on "Present Status of Tuberculosis in Palestine," and Ernst Wodak on "Plastic Surgery." Under the heading of "Historical Medicine" Dr. Leon Nemoj of Yale University, New Haven, Conn., writes on the great philosopher and physician of the thirteenth century—Ibn Kammuna. Dr. Yom-Tov Levinsky discusses in his article on "Folklore Medicine" the legends surrounding frogs and spiders as healing agents. The editor is Dr. Moses Einhorn. The original articles are summarized in English. The editorial office of the *Hebrew Medical Journal* is at 983 Park Avenue, New York 28.

CORRECTION

Liver Extract in Treatment of Cirrhosis of Liver.—The first sentence in this abstract from the *Review of Gastroenterology* for October 1947 (THE JOURNAL, January 17, p. 210) should have read: Rawls and Ancona report on 22 patients with cirrhosis, 18 with Laennec's and 4 with biliary cirrhosis, who received treatment for four months or longer.

Marriages

CALVIN WINFIELD APPLEWHITE, New Orleans, to Miss Laverne Louise Viverette of Union, Miss., Sept. 5, 1947.

JAMES ALTO WARD JR., Birmingham, Ala., to Miss Audrey Mary Charbonnet of New Orleans, Oct. 27, 1947.

LEWIS EDWARD JONES, Norfolk, Va., to Miss Margaret Louella Williams of Milford, Del., Sept. 23, 1947.

MANUEL DE MELLO, New Bedford, Mass., to Miss Helen Pimental of Mattapoisett, Sept. 17, 1947.

Deaths

Clarence Orion Cheney, White Plains, N. Y., for many years professor of clinical psychiatry, Cornell University Medical College in New York, died Nov. 4, 1947, aged 60, of cerebral hemorrhage. Dr. Cheney was born in Poughkeepsie, N. Y., July 10, 1887. After graduating from Columbia University College of Physicians and Surgeons, New York, 1911, he became pathologist at the Manhattan State Hospital. In 1917 he was named assistant director at the New York State Psychiatric Institute, serving until 1922, when he became assistant superintendent of the Utica State Hospital. Later he was medical superintendent of the Hudson River State Hospital, Poughkeepsie. He was medical director at the New York State Psychiatric Institute and Hospital, Columbia-Presbyterian Medical Center in New York, from 1931 to 1936, when he became medical director at the New York Hospital-Westchester Division, in White Plains. He was instructor in psychiatry at Cornell, at the University and Bellevue Hospital Medical College, and at the Syracuse University College of Medicine. Later he was professor of psychiatry at Columbia. In 1944 Columbia University awarded him its medal for professional distinction and public service. He was a president and secretary of the American Psychiatric Association, and when the association established a certification board in 1933 he was the first chairman. He was also a fellow of the American College of Physicians and the New York Academy of Medicine; a president of the New York Psychiatric Society; member of the American Medical Association; formerly secretary and chairman of the section on neurology and psychiatry, Medical Society of the State of New York; past president of the Dutchess County Medical Society; honorary member of the St. Louis Medical Society, and corresponding member of the Royal-Medico Psychological Association (England). Dr. Cheney was a member of the National Committee for Mental Hygiene, a charter member of the American Board of Psychiatry and Neurology and representative of the New York State Medical Society on the Board of Psychiatric Examiners of the New York State Department of Mental Hygiene. During World War I Dr. Cheney served on the local draft board and the Cornell Medical Advisory Board, and during World War II was psychiatrist to the medical advisory board of Westchester County and psychiatric examiner for the selective service induction staff in New York. He was awarded the Congressional Selective Service Medal in 1945. He was consulting psychiatrist to numerous hospitals and since 1946 had been consultant for the Veterans Administration in New York. Dr. Cheney published many studies dealing with psychiatry and the administration of mental hospitals. He was an associate editor of the *American Journal of Psychiatry* and the *Psychiatric Quarterly*.

Kingsley Roberts © New York; born in New York Dec. 29, 1893; Jefferson Medical College of Philadelphia, 1920; fellow of the American College of Surgeons and the New York Academy of Medicine; member of the American Public Health Association, American Hospital Association, American Public Welfare Association, Academy of Political Science and American Academy of Political and Social Science; served in the U. S. Naval Reserve during World War I; medical director of the Bureau of Cooperative Medicine from 1936 to 1941, when he became executive director of the Medical Administration Service; chairman of the medical advisory board of the Group Health Cooperative, Group Health Federation of America; affiliated with the Flower and Fifth Avenue Hospital, where he died Nov. 21, 1947, aged 53, of acute hepatitis.

William John L. McCullough © Washington, Pa.; born in Crosscreek, Pa., Feb. 10, 1880; Jefferson Medical College of Philadelphia, 1905; past president of the Washington County Medical Society; served during World War I; surgeon of the medical advisory board during World War II; member of the American Association of Industrial Physicians and Surgeons; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; chief surgeon of the Hazel Atlas Glass Company; affiliated with the Washington Hospital; died Nov. 3, 1947, aged 67, of coronary thrombosis.

George Aiken Dowling © Seattle; born Little Valley, Minn., Jan. 24, 1879; Northwestern University Medical School, Chicago, 1905; specialist certified by the American Board of Internal Medicine; member of the North Pacific Society of Internal Medicine; fellow of the American College of Physicians; past president of the Pacific Northwest Medical Association; served during World War I; cited for selected service work during World War II; served as attending physician and secretary of the Virginia Mason Hospital; died recently, aged 68, of cerebrovascular accident and hypertension.

Gerrit F. Blauvelt © Nyack, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1873; past president of the Rockland County Medical Society and vice president of the Medical Society of the State of New York; one of the founders, and for many years on the staff and honorary chairman of the board of managers of Nyack Hospital; died Nov. 12, 1947, aged 98, of arteriosclerosis.

Alexander Borland, Pontiac, Mich.; University of Louisville (Ky.) Medical Department, 1905; member of the American Medical Association; a medical officer during World War I; served as director of health at the Michigan Agricultural College in East Lansing; for two years deputy coroner of Oakland County; affiliated with St. Joseph Mercy and Pontiac General hospitals; died recently, aged 72.

Laura Mary Hobbs Bourne © Miami, Fla.; Western Reserve University School of Medicine, Cleveland, 1932; interned at the Columbia Hospital in Wilkinsburg, Pa., and the Biltmore Hospital; member of the courtesy staff of the Jackson Memorial Hospital, where she died recently, aged 42.

Adrian LeRoy Cambre © Atlanta, Mo.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1907; died Nov. 3, 1947, aged 67, of cerebral hemorrhage.

Edward D. G. Conkling, Newark, N. J.; New York Homeopathic Medical College and Hospital, New York, 1890; died in the East Orange (N. J.) General Hospital, Nov. 5, 1947, aged 85, of suppurative diverticulitis.

John Webster Cressler, Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1913; member of the American Medical Association; died recently, aged 59, of cardiovascular disease.

William Kenneth Edwards © Centerville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1913; formerly secretary of the Hickman County Medical Society; served during World War I; died Nov. 16, 1947, aged 57, of coronary occlusion.

John Marion Ellis, Mount Pleasant, Texas; College of Physicians and Surgeons, Little Rock, 1911; died recently, aged 61, of nephritis and hypertension.

Edward P. Goodrich, Winterport, Maine; Baltimore Medical College, 1896; member of the American Medical Association; county medical examiner; for many years state district health officer and state physician, residing in Lewiston; died recently, aged 73, of cerebral thrombosis.

Daniel Webster Gross, Worthington, Minn.; Jenner Medical College, Chicago, 1899; died Nov. 2, 1947, aged 82, of cirrhosis of the liver.

William Hall, Halls, Tenn.; Memphis (Tenn.) Hospital Medical College, 1911; died in the Baird-Brewer Hospital, Dyersburg, recently, aged 67, of undulant fever.

John Moore Hickman, Westville, Ill.; Medical College of Ohio, Cincinnati, 1896; died Nov. 18, 1947, aged 75, of carcinoma of the stomach.

Jesse S. Hopkins, Nashville, Ark.; University of Nashville (Tenn.) Medical Department, 1906; died Nov. 24, 1947, aged 69.

Clarence P. Lathrop, Hastings, Mich.; Chicago Homeopathic Medical College, 1890; member of the American Medical Association; founder and past president of the Barry County Medical Society; for many years county coroner; formerly assistant superintendent of the Ionia (Mich.) State Hospital; died Nov. 13, 1947, aged 77, of coronary occlusion.

Philip Max Le Beau, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; affiliated with the Belmont Hospital, where he died Nov. 9, 1947, aged 62, of coronary heart disease, chronic peptic ulcer and arteriosclerosis.

Ruffin Longest, Wynne, Ark.; University of Nashville (Tenn.) Medical Department, 1899; died recently, aged 78, of carcinoma of the colon and liver.

William Halbert Martin, Holly Grove, Ark.; University of Tennessee College of Medicine, Memphis, 1927; member of the American Medical Association; died in St. Joseph's Hospital in Memphis, Tenn., recently, aged 46, of heart disease.

James Egan McLoone © La Crosse, Wis.; Rush Medical College, Chicago, 1923; past president of the La Crosse County Medical Society; fellow of the American College of Surgeons; member of the Wisconsin Surgical Society; district surgeon for the Milwaukee and Burlington railroads; affiliated with St. Francis Hospital; shot and killed Nov. 14, 1947, aged 49.

Samuel P. Mengel * Wilkes-Barre, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1894; member of the House of Delegates of the American Medical Association from 1924 to 1929 and from 1931 to 1940; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; affiliated with the Mercy and Wilkes-Barre General hospitals; chief surgeon for Lehigh Valley Coal Company; died Nov. 11, 1947, aged 77, of carcinoma of the thyroid.

Jennie E. Nesbitt, Vallejo, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1905; died in Orange recently, aged 86, of cerebral vascular accident and bronchopneumonia.

Upton Darby Nourse * Dawsonville, Md.; Georgetown University School of Medicine, Washington, D. C., 1900; served as president of the Montgomery County Medical Society; affiliated with the Frederick Memorial Hospital in Frederick, where he died Nov. 14, 1947, aged 71, of acute coronary thrombosis.

William Francis Peters, Homer City, Pa.; Medico-Chirurgical College of Philadelphia, 1916; served during World War I; died recently, aged 59, of heart disease.

Ellis Powell * West Monroe, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1918; president of the parish and city boards of health; affiliated with St. Fran-

De Mont Ryan * Dryden, N. Y.; Syracuse University College of Medicine, 1904; for many years president of the board of education; died recently in the Cortland (N. Y.) Hospital, aged 71, of cerebral thrombosis.

Ira Clarence Stayner, Spencerville, Ohio; Washington University School of Medicine, St. Louis, 1904; served as a member of the school board in Spencerville and as assistant physician for the Ohio State Institution for Feeble-minded at Apple Creek; died recently, aged 78, of cardiovascular renal disease.

John Wheeler Tullis, Long Beach, Calif.; Kansas City (Mo.) Medical College, 1889; served as town councilman and member of the school board; died Oct. 28, 1947, aged 95, of chronic myocarditis.

Guy Wallace, Oakland, Calif.; College of Physicians and Surgeons, Los Angeles, 1917; died in the Providence Hospital Nov. 4, 1947, aged 61, of cerebral hemorrhage.

Alonzo Higbee Waterman * Chicago; the Hahnemann Medical College and Hospital, Chicago, 1906; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served on the staff of Henrotin and Illinois Masonic hospitals; died Nov. 26, 1947, aged 67, of coronary thrombosis.

LIEUT. (JG) JOSEPH A. FEDEROWICZ *
(MC) U. S. Navy, 1916-1945

LIEUT. COMDR. GEO. R. HOGSHIRE JR.
(MC) U. S. Navy, 1906-1944

COMDR. THOMAS H. HAYES
(MC) U. S. Navy, 1897-1945

cis Sanitarium and Monroe Charity Hospital in Monroe; died in the Touro Infirmary, New Orleans, Nov. 12, 1947, aged 54, of adenocarcinoma of the liver with metastases and Laennec's cirrhosis.

Albert Zrunek * Chicago; Univerzita Komenského Fakulta Lékařská, Bratislava, Czechoslovakia, 1922; affiliated with the Chicago Memorial Hospital, where he died Nov. 19, 1947, aged 54, of coronary occlusion.

KILLED IN ACTION

Joseph Anthony Federowicz * Acting Assistant Surgeon Lieutenant (jg), U. S. Navy, Philadelphia; Jefferson Medical College of Philadelphia, 1942; interned at the Naval Hospital; served a residency at the French Hospital in New York; entered the U. S. Navy Oct. 14, 1943; killed in action June 16, 1945, aged 29.

George Riley Hogshire Jr. * Surgeon, Lieutenant Commander, U. S. Navy, Portland, Ore.; born in Lebanon, Ind., Jan. 11, 1906; University of Oregon Medical School, Portland, 1931; entered the U. S. Navy in 1931, interning at the U. S. Naval Hospital in Mare Island, Calif.; on duty at Pearl Harbor as junior medical officer on the U. S. S. *Beaver*; transferred to Bremerton Naval Hospital; then was assigned to the Destroyer Division and to the U. S. S. *Smith*; outpatient physician at the Naval Dispensary, Long Beach, Calif.; in February 1941 went to the Philippines,

where at the outbreak of war he served on Corregidor with the 4th Regiment of the Marines; after the fall of Corregidor was a ward medical officer in Bilid Prison; awarded the Silver Star, Bronze Star Medal and the Gold Star in lieu of the Second Bronze Star Medal; died in the Asiatic area Oct. 24, 1944, aged 38, when the ship on which he was being transported to Japan was sunk.

Thomas Hirst Hayes * Medical Inspector, Commander, U. S. Navy, Alexandria, Va.; George Washington University School of Medicine, Washington, D. C., 1920; entered the U. S. Navy as a lieutenant (jg) in August 1924; promoted through the various ranks; taken prisoner by the Japanese at the fall of Corregidor and held in Bilid Prison; killed Jan. 9, 1945, aged 46, while on a Japanese Prison ship which was bombed in a harbor in Formosa.

Jan. 8, 1948.

The National Health Service Act Opposition of the British Medical Association

The negotiations between the negotiating committee of the medical profession and the Minister of Health with regard to the National Health Insurance Act have at last been published and reveal a serious disagreement. The British Medical Association has sent to every member of the profession a statement of their objections with the minister's reply. They point out that the medical profession itself has provided the main impetus toward the establishment of a comprehensive medical service. From time to time since 1920 it has evolved statements of policy and published constructive proposals. Such differences as have arisen with the government relate not to the objective but to the means of reaching it. In the public interest the profession is opposed to any form of service which leads directly or indirectly to the members of the medical profession becoming full time salaried servants of the state. The profession should remain free to exercise the art of medicine according to its traditions, the individual doctor retaining full responsibility for the care of the patient. The citizen should be free to choose or change his family doctor; to choose with his family doctor the hospital in which he should be treated and to decide whether to avail himself of the public service or to obtain medical service independently. Doctors should, like other workers, be free to choose the form, place and type of work that they prefer, without governmental direction.

The two features of the act which have aroused the greatest misgiving in the profession are the abolition of the custom of buying and selling practices and the establishment of a machine of "negative direction" over the movements of general practitioners. On the need for better distribution of doctors the Minister of Health based his arguments for the abolition of ownership of goodwill in practice. But problems of distribution can be met in a satisfactory way by dealing with cases of under-doctoring as they occur. No areas will remain underdoctored because of inability to purchase medical service, for, as a result of the act, there will be available medical payment in respect of every member of the community. Any remaining deficiency in particular localities can be remedied by adjusting the conditions of service to attract practitioners to the underdoctored area. The abolition of the established practice of buying and selling practices would create more difficulties than it solves. Practically every existing partnership is governed by an agreement which provides that on the retirement, death or sickness of one partner the other partner or partners shall have the option, and often the obligation, to purchase the share of the outgoing partner. The altered position produced by the act will give rise to insurmountable difficulties in carrying out the agreement. A doctor may be required to buy a partner's public practice, the capital value of which he cannot realize, the income from which he cannot receive, and compensation for which is not available to him. It is in the best interest of the public that general practitioners should retain the ownership of the goodwill of their practices. This provides an important incentive, encourages good work and provides a basis for cooperation between doctors.

The act makes possible a state monopoly of hospitals and may also be applied to institutions not generally regarded as hospitals, such as nursing homes. State ownership of these is not

essential to the efficiency of the medical service and would deprive the profession of facilities for independent practice which are necessary for the maintenance of a high standard of medical practice. The fear is aroused that a Minister of Health may establish a monopoly in hospitals by compulsorily acquiring any private hospital or clinic. On public grounds he should not be allowed to establish such a monopoly. He also is given power to allow any practitioner on the staff of a hospital to treat his private patients at that or any other hospital. The committee holds that the minister's discretion should be replaced by an obligation to permit specialists in the service to attend their patients in private hospital accommodations.

THE MINISTER'S REPLY

In reply the Minister of Health says that the scheme in no way interferes with the doctor's relationship to his patients, of which the very essence should be personal and confidential. The object of the act is simple: it is to help, by public funds, to insure that any one—the highest or the lowest—should be confident of getting all the best that the great profession can give. If the members of the profession rally to it, the greatest health service in the world can come into being. A scheme of this magnitude is bound to need amending as it is found wanting. But in its conception it is of incalculable value to the great mass of the population, and the medical profession will be the first to want—as they have wanted—something of the kind. For his part, the minister is concerned mainly to get this great national scheme launched and to plan wider and wider lines, with the physicians directly cooperating in the management. He asks them to help him in launching and in constantly improving it as it goes along.

THE ATTITUDE OF THE BRITISH MEDICAL ASSOCIATION

The Council of the British Medical Association has issued a statement that on no single major issue has the minister responded to the reasoned arguments of the profession. On January 31 a plebiscite of all members of the profession will be taken, and on the result the British Medical Association will determine its future action. Whatever the result, no doctor will be advised not to render service to his patients or not to continue with his professional work. If the profession decides against service, consultants and specialists will be advised to continue with their hospital work, meanwhile refraining from entering into contract with regional hospital boards; general practitioners will be advised to continue with their practices but without entering into contract with local executive councils; health officers will be advised to continue with their work under local authorities.

Parliament has given to every doctor the right freely to enter or not to enter the service. The medical profession, while never willing to withdraw its services from the public, is fully entitled to say that the state service offered is, in its considered view, opposed to the best interests of the public and the profession. In spite of the minister's promise that he would, if convinced, seek amendment of the act, he has remained unconvinced and impervious to argument. Thus, for nearly a year the association has worked at the conference table to no purpose. The council asks whether the service, as described by the minister, conflicts with the traditions and standards of a great profession. They reply that there is only one answer that they can give to this question. It does so conflict. Thus the stage seems set for a great struggle between the government and the medical profession, which, with the great increase of membership due to the apprehensions aroused by the scheme, the British Medical Association can claim to fully represent. Like all socialistic schemes, this one is quite laudable in its intention but the practical difficulties of carrying it out are ignored.

Red Cross Society to Establish Hospitals in India

The withdrawal of British rule from India has taken place without any manifestation of gratitude for the benefits conferred by the introduction of European civilization. India has also chosen not to remain within the British Commonwealth of nations, of which each enjoys complete autonomy. This has caused some disappointment in this country, but nothing but goodwill has been manifest for the new states. This is shown by the efforts of the British Red Cross Society to relieve the distress in India. A beginning is to be made by establishing a hospital of two hundred and fifty beds, with room for another one hundred and fifty, at Lahore. Besides this main hospital there will be three subsidiary hospitals, each with fifty beds, and two or three mobile dispensaries with a fleet of twenty-four ambulances attached to them. The establishment of the hospital and its subsidiaries is expected to use up all the \$400,000 allocated by the society for relief in India as well as the money raised by subscriptions. The first hospital is expected to be ready for use in March, and its specialist staff of twenty persons is being formed in England. It will be headed by Colonel W. Lawe, who has had twenty-four years in the Indian Medical Service, the last thirteen of which were spent exclusively in work for the Indian civil population. The remainder of the staff is being recruited in India and Pakistan.

Four main hospitals will be needed in Pakistan to provide even the foundations of an adequate relief scheme. To maintain them will cost \$800,000 a year. Because of the climate in the Lahore region tent hospitals would be most unsuitable, especially in the hot season. Materials will be divided between India and Pakistan, but only Pakistan has asked for a staff.

BOLIVIA

(From Our Regular Correspondent)

LA PAZ, Dec. 18, 1947.

Life Expectancy at High Altitudes

Are there any effects of continuous exposures to high altitudes on birth rates, mortality and life expectancy? The city of La Paz, with 300,000 inhabitants, is situated at 12,000 feet (3.66 kilometers) above sea level. There are also other regions in this country which are at average levels, around 1,000 feet (0.3 kilometer) above sea level.

A preliminary study based on figures for 1942 to 1944, has been released by the statistical office, which in turn has collected them through the regular channels of the registrars' offices all over the country. In this study, the country was divided into three sections, each consisting of three districts. The first section, zone 1, comprises those districts where most inhabitants live constantly at average altitudes exceeding 10,000 feet (3 kilometers); zone 2, those districts with an average altitude between 3,000 and 10,000 feet (0.9 and 3 kilometers), and, finally, zone 3, those districts which are situated at an average altitude of less than 3,000 feet (0.9 kilometer).

The population investigated was comprised of whites, 17.6 per cent; mestizos, 30.6 per cent; Indians, 51.5 per cent, and other races, 0.3 per cent.

The country actually has 3,786,500 inhabitants, distributed to the aforementioned districts and zones.

Over half the population (57 per cent) lives and works constantly on levels above 10,000 feet (3 kilometers), and a certain part even at altitudes as high as 15,000 feet (4.57 kilometers) above sea level.

As to the climate, zone 1 is moderately cool, with an average annual temperature of about 9 C. (48 F.); zone 2 has a sub-tropical climate and an annual average temperature of 17 C. (62.6 F.), and zone 3 is tropical, with an annual average temperature as high as 25 C. (77 F.). The inhabitants of each zone

can be considered as completely acclimated to their respective altitudes, as only relatively few of them ever move from one zone to another.

BIRTH AND DEATH RATES

Altitude seems to have relatively little influence on the birth rates. Surprisingly enough, birth rates are higher in zones 1 and 2, above 3,000 feet (0.9 kilometer). Natality rates were best in zone 2 and were followed by those of the highland (zone 1). Thus low atmospheric pressure seems to have no untoward effect on the birth rate, considering that practically all the inhabitants were acclimated. Conditions for unacclimated persons are somewhat less favorable.

The mortality rates were almost identical in the two zones (1 and 2) above 3,000 feet (0.9 kilometer), but they were comparatively higher than in the lowlands (15.7 per cent as against 9.3 per cent). This large difference between the zones is noteworthy, but no definite reason can be offered so far. Excessive differences with regard to individual cause of death in each zone, which eventually could account for that surprising observation, were not detected; only diseases of the respiratory tract were somewhat above the average figures in zone 1. The annual increase of population was highest in zone 3, the lowest section of the country.

INFANT MORTALITY

Infant mortality is a major problem all over South America, and thus the comparatively high figures are not surprising. The average death rate for children under 1 year of age for 1944 works out at 133.3 per thousand living children. The figure compares not unfavorably with that of some other countries of the Continent.

The effect of altitude on infant mortality is noteworthy. Although in the lowlands (zone 3) with its tropical climate and high incidence of malaria the annual mortality rate stayed at 93.3 per thousand, the corresponding figure for the highlands (zone 1) was 142.2 per thousand. Thus a baby born near sea level had 50 per cent more chance to survive his first year of life than did his companion at 10,000 feet (3 kilometers). The relative frequency of whooping cough and congenital weakness accounts for some of the additional deaths in zone 1, but does not explain completely the difference as against zone 3 (lowland); nor are there any better hospital and medical facilities in the lower sections of the country than in the higher ones.

Death Rates in Other Age Groups

Striking differences due to altitude became evident in the death rate of the age group from 1 to 5 years. While only one eighth of all the deaths belonged to that group in zone 3, in zone 1 more than one quarter of the deaths had been in that age group. Again no one specific disease could be blamed for this relative excess in zone 1, even though diseases of the respiratory tract were somewhat more frequent in that section.

Less striking were the differences in the age group from 5 to 14 years, but even there the child in the lower altitudes had a better chance of survival. Figures for the age groups from 25 to 64 show a lower death rate in zone 1; figures for the ages above 65 are fairly mixed for all the sections. The average ages at death were as follows: zone 1, about 31 years; zone 2, about 34 years, and zone 3, about 37 years.

Thus life expectancy in the lower sections was also found to be much better than in the highest zone.

CONCLUSIONS

1. Continuous exposure to excessive altitudes results in a sharp rise of infant and child mortality, and therefore in a reduced life expectancy even in acclimated persons.

2. This same continuous exposure seems to be without any untoward effects on the birth rates; on the contrary, those rates were even better in the higher sections.

Correspondence

ESTIMATION OF PROTHROMBIN TIME

To the Editor:—The opinion grows that the results of estimation of prothrombin time should be reported in terms of per cent or of per cent of normal. Recently, a plea has been made that the practice be made universal (Allen, E. V.: *THE JOURNAL*, page 323, May 24, 1947). The main reason for the suggestion has been stated by Barker, Hines, Kvale and Allen: "If clinicians become accustomed to discussing concentrations of prothrombin in terms of percentage rather than time, it is possible to compare the results of the tests performed in many institutions or by individual physicians in different institutions" (*Ann. J. Med.* 3:636 [Nov.] 1947). Percentage figures in most published reports are based on the construction of a curve of average prothrombin times of serial dilutions of normal plasmas plotted against the dilutions of these plasmas expressed in the percentage of whole plasma. Not infrequently, there is no statement as to how the percentage figure is obtained. Albeit, in using this concept several facts must be considered:

The conversion to percentage must be obtained from a curve derived from the activity of the particular thromboplastin used. Otherwise, it may be misleading. This is obvious from the degree of variation in prothrombin time-per cent curves obtained by different workers. (An excellent example of this occurs in the brochure published by a pharmaceutical house marketing "dicumarol," E. R. Squibb & Sons). Thus, Aggeler and others (*Blood* 1:220 [May] 1946) report whole plasma prothrombin time 11.5 seconds and 12.5 per cent plasma prothrombin time 55 seconds. Shapiro (*Exper. Med. & Surg.* 2:103 [May] 1944) reports prothrombin time of whole plasma 16 seconds and of 12.5 per cent plasma 40 seconds. To be accurate, each worker must construct his own curve on the basis of the clotting time characteristics of the thromboplastin he uses. He then determines the per cent solely by prothrombin time. When this is done, he can just as readily establish values, in time, for "dicumarol" therapeutic range or for normal limits.

The use of the term percentage prothrombin is misleading because it implies expression of the concentration of prothrombin. (See preceding statement by Barker and associates.) Actually, it is the clotting activity of an altered sample of plasma which is being estimated. Rapoport (*Proc. Soc. Exper. Biol. & Med.* 64:478 [April] 1947) has shown that when plasma with reduced prothrombin activity is diluted, its dilution curve is not superimposable on that portion of the normal prothrombin time-per cent curve which it should theoretically duplicate. Furthermore, Shapiro and others have called attention to the lack of uniformity in the relationship of whole and diluted plasma prothrombin time in certain pathologic states, i. e., a reduced difference between whole and diluted plasma prothrombin time in hyperprothrombinemia (*Proc. Soc. Exper. Biol. & Med.* 50:85, 1942; Shapiro and others, *J. Clin. Investigation* 22:137, 1943).

In view of these facts it seems clear that unpredictable errors may enter when the curve constructed from normal plasma is applied to a result obtained with pathologic plasma in which substances other than prothrombin may affect prothrombin time.

Given samples of plasma do not invariably yield the same per cent prothrombin activity when determined by different thromboplastins, even if the respective prothrombin time-per cent curves are used. These facts minimize the claim that reporting results in terms of per cent makes it possible for different workers using different thromboplastin preparations to quantitatively compare their results more easily than if results are reported in terms of time. By analogy one may ask, what service would it render to report blood cholesterol or sugar or red blood cells in per cent of normal? The unjustified assumption of accuracy which the percentage figure connotes is exemplified in the expression of basal metabolic rate in terms of per cent.

It seems to us that to follow adequately the prothrombin response to "dicumarol," the clinician should know the normal range of the thromboplastin used and the therapeutic range he wishes to establish in terms of time. With this knowledge the calculation of percentage is superfluous; without it the percentage figure is misleading. Of additional importance is the fact that use of figures as percentage of normal may rapidly acquire the connotation of a sense of accuracy which has not been proved. Estimation of prothrombin time is, at best, an indication of the in vitro clotting capacity of a specimen of plasma obtained and studied under certain standardized conditions.

In pathologic conditions, such as thrombotic or hemorrhagic states, certain interfering or accelerating substances can be demonstrated in the blood (Shapiro: *Proc. New York Path. Soc.* 1946-1947, to be published). These substances generally lose their activity in plasma diluted 1:8. Hence, by measuring the values of whole and diluted (12.5 per cent) plasma, the clinician may gather information which may be of more clinical significance than either single estimation. Such phenomena escape detection when percentage figures are quoted.

The application of estimation of prothrombin time in clinical medicine is not confined to following responses to "dicumarol." Diluted (12.5 per cent) plasma prothrombin time and response to vitamin K can be used as a liver function test. It has many uses in detecting and categorizing certain dyscrasias of the blood. The method demands the use of a standardized thromboplastin. If a thromboplastin preparation with an optimum range of activity should be adopted as the universal standard, there would be no difficulty in comparing results obtained in the various laboratories. With such a system, the results could be given in time, and it would eliminate the need for additional means of calculation, including percentage values.

SHEPARD SHAPIRO, M.D.

MURRAY WEINER, M.D.

New York.

FELLOWSHIP IN STUDY OF ATOMIC ENERGY

To the Editor:—For some time the Atomic Energy Commission has been concerned with the shortage of trained personnel in the fields of medicine and biology as they apply to atomic energy. Because of the importance of a broad program for the study of these fields, the Atomic Energy Commission announces a fellowship training program, which includes a number of fellowships for doctors of medicine. These doctors of medicine will receive two years of intensive training in atomic energy as it applies to medicine.

The program will be administered by the National Research Council, and further detailed announcements will be forthcoming in the near future with the hope that a group of fellows may begin training by Sept. 1, 1948. There will be an adequate stipend with consideration of the marital status of the fellows. Training will include formal instruction in such essential subjects as chemistry, biology, physics and mathematics, with particular emphasis on their application to the medical aspects of atomic energy. It is planned that after a year of such fundamental training, the fellows would enter into fundamental and clinical research programs which are in progress at the various regional laboratories of the commission. At the termination of their training, fellows will be free to follow careers of their own choice. However, there will be opportunities for suitable candidates in the various medical facilities of the commission, and with the amplification of medical school departments in this field there will be opportunities in such institutions. It is hoped that such a fellowship program will produce a group of well trained physicians in this new and vital field.

SHIELDS WARREN, Washington, D. C.

Interim Director, Division of Biology and Medicine.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Validity of Law Permitting Detention of Prostitutes for Venereal Examination.—The petitioner filed an original action in habeas corpus to secure her release from confinement in the city jail of Oklahoma City. The case was heard in the criminal court of appeals of Oklahoma.

The petitioner was arrested in an apartment house on the evening of May 11 and placed in the city jail with the booking "vagrancy by prostitution, investigation, and hold for clinic." The next afternoon she pleaded guilty to the charge of vagrancy before the police judge, who directed that she be taken to the venereal disease clinic for examination. There a specimen for a slide examination was immediately taken to determine whether she had gonorrhea. At the same time, a specimen for a culture was taken and sent to the state laboratory for examination. The proof showed that the examination of the slide would disclose within just a few hours whether the patient was infected but that it took forty-eight hours to get the result of the culture test. The examination of the slide was negative, but at the time of the hearing the laboratory had not completed its test on the culture.

The law under which the respondent justified his restraint of the petitioner provided: "The keeper, manager, guard or person in control of every prison or penal institution in this state shall cause to be examined every person confined in such prison or penal institution after conviction for any offense, to determine whether such person is an infected person. State and local Health Officers, or their authorized deputies who are physicians, are empowered to examine those who are arrested by lawful warrant for vagrancy, prostitution, rape or other sex crimes for the purpose of determining if they are infected with venereal disease. Every such person shall submit to such examination and permit specimens to be taken for laboratory examinations. Such person may be detained until the results of such examination are known. The required examination shall be made by the Health Officer, or, at the option of the person to be examined, by an approved licensed physician. All persons found to be infected with a venereal disease shall be treated by the local Health Officer or a licensed physician of their own choice until said person is noninfectious or dismissed by said physician. In the event such person infected with a venereal disease refuses or fails to submit to treatment, then said person may be quarantined for the purpose of treatment and reported to the State Board of Health."

The petitioner contended that the foregoing statute is unconstitutional for the reason that it amounts to forcing a person to give testimony against one's self and constitutes an illegal delegation of legislative authority. She further contended that the rules, procedure and acts on the part of the police department in the manner in which they effected her arrest and detention were illegal and unconstitutional throughout. In a prior case construing the venereal disease act of 1919, the criminal court of appeals said: "The power of the Legislature to prevent the introduction and spread of infectious and contagious diseases cannot be questioned, and the power to make quarantine regulations is one of the most important conferred upon the health authorities, and such regulations constitute a proper exercise of police power."

The petitioner contended that a police officer may not arbitrarily arrest a person on suspicion of a communicable venereal disease but that such fact must be judicially determined before the infected person may be restrained of her liberty or detained for examination and treatment. The court pointed out that the only person in Oklahoma City who commits a suspected infected person to the clinic for examination is the police judge, and he does so only when the proof before him shows that the suspected person is one of the class named in the statute. Here, the peti-

tioner was a known prostitute who admitted that she had at one time been infected with a venereal disease. Certainly, if the statute is constitutional, there were sufficient grounds for the police judge to believe that the petitioner should be detained at the clinic until her venereal tests were completed. Counsel for the petitioner contended that the policemen are making it so tough for the petitioner through numerous arrests, and holding her for examination at the clinic, that it results in the petitioner spending a large part of her time in illegal restraint. The petitioner plead guilty to vagrancy by prostitution committed on the night of May 11. If she continues to follow the illegal profession of prostitution, one of the hazards that she must contemplate is that the police might arrest and prosecute her for such conduct and as a necessary corollary to such arrest detain her in the quarantine ward for examination in order to protect that part of the public who might seek the services of the petitioner in her profession from becoming infected with a communicable venereal disease.

The adoption of laws for the protection of public health is universally considered to be a valid exercise of the police power of the state as to which the legislature is necessarily vested with large discretion, not only in determining what are contagious and infectious diseases but also in adopting means for preventing the spread thereof. The act in question specifically names the conditions under which a suspected person may be detained for examination. If a person is lawfully arrested for one of the crimes mentioned in the statute and the officers mentioned are of the opinion that an examination should be given to determine whether that person is infected with a venereal disease, the suspected person is entitled as a matter of right to have the test given as speedily as is possible so that her quarantine will not be longer than is absolutely necessary to determine whether there is an infectious disease. One of the most important rights guaranteed under our constitution is liberty of the citizen. This cannot be lightly passed over. We will not allow an encroachment on that right except in an emergency occasioned by danger to the public health and then only in strict compliance with the statutes.

It is our conclusion, said the court, that the statute in question does not make an illegal delegation of legislative authority. If the petitioner is right in her contention that the policemen acted maliciously and detained her an unnecessary length of time under the pretense of giving her venereal tests, her recourse is in the civil courts. We wish, however, to emphasize that officers who are sworn to enforce the law, in following the statute which has been given them for the purpose of combating the spread of venereal disease, should not use such authority as a cloak to give unwarranted and additional punishment to persons on the ground that they are suspected of infection with a venereal disease. Accordingly the petitioner's request for the writ of habeas corpus was denied.—*Ex parte Fowler*, 184 P. (2d) 814 (Okla., 1947).

Workmen's Compensation Acts: Inhalation of Dust as Cause of Heart Ailment.—The petitioner filed a claim for a compensation award, which was granted by the referee. The referee's award was reversed by the commission but later affirmed by the circuit court. Accordingly the employer appealed to the Supreme Court of Arkansas.

The petitioner had worked for the Batesville White Lime Company for twenty-three years, and much of the time his duties kept him around a rock crusher where the air was heavily impregnated with dust. After the petitioner's claim was filed, the matter was referred to a medical board in conformity with the Arkansas workmen's compensation law, which reported that it found no evidence of petitioner's being afflicted with silicosis or tuberculosis but found "that the inhalation of dust in the employment has aggravated a preexisting heart condition, which in our opinion renders the claimant totally and permanently disabled from following any occupation." On the basis of this report, the referee granted an award. The employer and the commission took the position that, since this inhalation of dust continued over a period of years, so that the damage to the petitioner's heart by the additional strain imposed on it was

probably gradual, there was no trauma which would admit of a finding of accidental injury within the meaning of the term as used in the workmen's compensation law.

The Supreme Court first pointed out that the terms of the workmen's compensation act must be given a liberal interpretation in favor of the claimant and, further, that the Arkansas act provides that "there shall be a prima facie presumption . . . that the claim comes within the provisions of this Act." Continuing, the court said that the word "accidental" has often been construed to mean "unexpected," "fortuitous" or "not to be reasonably anticipated." Now there is nothing in the proof in this case, said the court, to justify a conclusion that the injury to the petitioner's heart by breathing the excessive amount of dust was one which the petitioner might have reasonably expected or anticipated. Certainly it was accidental as far as he was concerned; and there is much authority for a holding that an injury which is not necessarily the result of one impact alone but is caused by a continuation of irritation on some part of the body by foreign substances may properly be said to be accidental. After citing numerous cases bearing on the issue, the Supreme Court concluded that even though the evidence did not show the exact instant at which the disability of the petitioner could be said to have occurred by reason of breathing the dust, nevertheless, as shown by the proof, the inhalation of the dust did aggravate the petitioner's cardiac ailment to the point of totally disabling him. The judgment of the circuit court affirming the referee's award was therefore affirmed.—*Batesville White Lime Co. v. Bell*, 205 S. W. (2d) 31 (Ark., 1947).

Medical Motion Pictures

NEW MOTION PICTURES ADDED TO A. M. A. FILM LIBRARY

Clinical Malaria. 16 mm., black and white, sound, 1,000 feet (one reel), showing time twenty-eight minutes. Produced in 1944 for the Bureau of Medicine and Surgery, U. S. Navy, by Audio Productions, Inc., New York. Procurable on loan from the American Medical Association, Committee on Medical Motion Pictures, 535 North Dearborn Street, Chicago 10.

"Clinical malaria" is a basic teaching film. By a combination of actual photography and animation, the relationship of the life cycle of the malarial parasite in the blood stream to the patient's clinical symptoms is clearly shown. The symptoms, signs and pathologic bodily changes associated with the three common types of infection (benign tertian, quartan and malignant tertian) are depicted.

This film is recommended for the general practitioner and medical student.

Moles and Melanoma. 16 mm., color, sound, 350 feet, showing time eight minutes. Prepared in 1945 for the Bureau of Medicine and Surgery, U. S. Navy, by Pathoscope, New York. Procurable on loan from the American Medical Association, Committee on Medical Motion Pictures, 535 North Dearborn Street, Chicago 10.

By animation the structure and skin cells of benign and cancerous moles are illustrated. The film shows the ineffective results with improper removal of a mole and the proper procedures that insure good results.

It is recommended that this picture be shown to general practitioners and medical students.

Plague Control. 16 mm., color, sound, 800 feet (one reel), showing time twenty minutes. Produced in 1945 for the Bureau of Medicine and Surgery, U. S. Navy, by Pathoscope, New York. Procurable on loan from the American Medical Association, Committee on Medical Motion Pictures, 535 North Dearborn Street, Chicago 10.

This film introduces the problems created by plague; it identifies types, carriers and characteristics of the disease, control and preventive measures. It stresses the importance of effective programs for rodent and flea control.

This picture is recommended for the general practitioner, medical student and public health worker.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, Jan. 31, page 349.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Examination, Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ALASKA: * Juneau, March 2. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: * Examination, Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Electric*: Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral*. San Francisco, June 5-6; Los Angeles, Feb. 28-29. *Written Examination*, Los Angeles, March 1-4. *Oral and Clinical Examination for Foreign Graduates*, Los Angeles, Feb. 29; San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

COLORADO: * Examination, Denver, June 21-23. Final date for filing application is June 5. *Endorsement*, Denver, April 6. Final date for filing application is March 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * Examination, March 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination*, Derby, March 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity*, Washington, D. C., March 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 E Municipal Bldg., Washington.

FLORIDA: Examination, Jacksonville, June 29-30. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

INDIANA: Examination, Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

IOWA: Examination, Iowa City, March 15-17. Comm., Dr. Walter L. Bierring, Dept. of Health, Des Moines.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Examination, Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: Medical Examination, Baltimore, June 15-18. Sec., Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination*, Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Examination, Boston, March 9-12. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston. *Mississippi*: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. M. Whitfield, Jackson.

MONTANA: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA: * Examination, Omaha, April 12-14. Dir., Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

NEVADA: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Examination, Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: Examination, Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW YORK: Examination, Albany, Buffalo, New York, Syracuse, Feb. 16-19. Sec., Dr. J. L. Lochner, Jr., Education Bldg., Albany.

NORTH CAROLINA: *Endorsement*, Pinehurst, May 4. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

OHIO: *Endorsement*, Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

RHODE ISLAND: * Examination, Providence, April 1-2. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Written Examination*, Columbia, June 21-23. *Endorsement*, March 1. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

TEXAS: Austin, Feb. 19-21. Asst. Sec., Mrs. Laura McElroy, 918-20 Texas Bank Bldg., Dallas 2.

UTAH: Examination, Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: Examination, Richmond, June 18-19. *Endorsement*, Richmond, June 17. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 23-29. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: Examination, Tucson, March 16. Sec., Mr. Francis A. Roy, Science Hall, Univ. of Arizona, Tucson.

ARKANSAS: Little Rock, May 4. Sec., Mr. L. E. Gebauer, 1002 Dragey Bldg., Little Rock.

COLORADO: Examination, Denver, March 3-4. Final date for filing application is Feb. 18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

DISTRICT OF COLUMBIA: Examination, Washington, April 19-20. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington.

FLORIDA: Examination, June 5. Final date for filing application is May 23. Sec., Mr. M. W. Emmel, Univ. of Florida, Gainesville.

IOWA: Des Moines, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MINNESOTA: Examination, Minneapolis, April 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

OKLAHOMA: Oklahoma City, March 1. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Examination, Portland, March 6. Sec., Basic Science Examining Committee, Mr. C. D. Byrne, Univ. of Oregon, Eugene.

TENNESSEE: Memphis, March 15-16. Sec., Dr. O. W. Hyman, Univ. of Tennessee, 874 Union Ave., Memphis.

WISCONSIN: Examination, Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted

American Journal of Clinical Pathology, Baltimore

17:761-846 (Oct.) 1947. Partial Index

- Utilization of Vitamin B₆ Conjugate in Pernicious Anemia. E. A. Sharp and E. C. Vonder Heide.—p. 761.
- Effect of Lipids on Kahn Antigen: III. Increasing Sensitivity of Kahn Standard Antigen to Level of Kahn Sensitized Antigen by Addition of Alcoholic Extract of Soy Bean Lecithin. A. H. Wheeler and Ella M. Brandon.—p. 770.

- Characteristic Urinary Findings in Visceral Angiitis (Periarthritis Nodosa, Lupus Erythematosus). J. B. Male.—p. 820.

Recovery After Receiving Incompatible Blood.—

According to Young and his associates the reported mortality from transfusion of blood incompatible with respect to the major blood groups is approximately 50 per cent and is roughly proportional to the quantity of blood given. Death occurred within twenty-four hours in most cases when more than 500 cc. of incompatible blood was transfused. In the case reported in this paper, 2,000 cc. of group A blood was transfused into a group O patient as a result of improper identification of the recipient when blood was drawn for cross matching. The patient apparently recovered completely from the hemolytic reaction but died fifty-three days later of carcinoma of the lung and pyothorax. Necropsy failed to reveal more than minimal evidence of renal damage or other abnormalities which could reasonably be attributed to the transfusion. This case suggests among other factors that the recipient's chances of survival may depend not only on the quantity of blood transfused but also on such factors as urinary β_n , isoagglutinin titer, presence of cancer and infection and state of anesthesia. Hemolytic reactions occurring in patients under general anesthesia may not be detected unless close attention is paid to the development of jaundice, oliguria and hemoglobinuria. When blood grouping and blood matching are repeated after a suspected hemolytic reaction, it is essential that examination be made of the patient's blood taken after transfusion as well as of the patient's blood taken before transfusion.

American J. Digestive Disease, Fort Wayne, Ind.

14:315-340 (Oct.) 1947

- Metabolism of Sucrose: II. I. M. Rabinowitch.—p. 315.
- System of Diabetic Diet Prescription for General Practitioner. C. P. Lamar.—p. 323.
- *Etiology of Protruded Gastric Mucosa: with an Illustrative Case Report. S. P. Bralow and M. A. Spellberg.—p. 332.

Etiology of Protruded Gastric Mucosa.—Bralow and Spellberg report on a man, aged 57, who had been hospitalized for duodenal and prepyloric ulcer on seven occasions. The sequence of benign peptic ulceration followed by gastritis which, on healing, produces hypertrophic gastric rugae and later a prolapse of gastric mucosa into the duodenal bulb appeared as the possible etiologic mechanism in this case. This mechanism probably plays a more general role in the causation of prolapse. An attempt is made to explain the results of two other observers who have recently reported on prolapse of the

gastric mucosa on the same basis. The authors believe that surgical treatment should be restricted to patients with intractable pyloric obstruction. Two more patients exhibiting the possible sequence of ulcer-gastritis-prolapse were admitted to the Veterans Administration Hospital, Hines, Ill.

American Review of Tuberculosis, New York

56:267-372 (Oct.) 1947

- Twelfth Pan American Sanitary Conference: Caracas, Jan. 12 to 24, 1947. E. R. Long.—p. 365.
- Primary Infection and Progressive Tuberculosis. M. Pinner.—p. 368.

Late Primary Infection and BCG Vaccination.—According to Malmros, late primary infection is a common cause of progressive pulmonary tuberculosis in young persons and adults. The frequently employed terms reinfection and reinfection type are misleading and should be abandoned. This concept determines to a high degree the preventive tuberculosis campaign in the Scandinavian countries. Since experiences suggest that nonreactors are especially exposed to the risk of contracting tuberculosis if they become infected, in Sweden all medical students and pupil nurses are now tuberculin tested before beginning hospital service, and the nonreactors are vaccinated. Conscripts in the services are vaccinated at the beginning of their term of service, and so are the majority of school children in the last class of primary school before their final examinations. Still more extensive vaccinations have been performed in certain districts. During the years 1942 to 1946, the whole population of 230,000 in the Örebro district was tuberculin tested, and about 18,000 nonreactors have been vaccinated with BCG under the author's supervision. No complications of any serious nature occurred. Over one fourth of the vaccinated persons consisted of newborn babies; 6,100 had attained the age of 15 years at the time of vaccination. During this period only 3 cases of suspected tuberculosis were reported among the 18,000 who were vaccinated. Under no circumstances should students of nursing and medicine be allowed to perform duties at hospitals if they are tuberculin negative. Only such hospitals as exert scrupulous tuberculosis control, including BCG vaccination of all nonreactors to tuberculin at least six weeks prior to the beginning of their service, should be accepted as training hospitals. A modern tuberculosis control program should include miniature photofluorography of all adults and children over 14 years of age, tuberculin testing of the whole population and vaccination of all nonreactors with BCG. It should be checked by follow-up examinations to see that the vaccinated persons remain tuberculin positive. Should the tuberculin reaction again become negative, revaccination is indicated.

Asthma in Pulmonary Tuberculosis.—Cohen states that the disease of 55 of 7,301 patients discharged from Olive View Sanatorium in the period from July 1, 1936 to July 1, 1946 was diagnosed as pulmonary tuberculosis and bronchial asthma, an incidence of 0.75 per cent. Of these, 36 seem to have an adequate basis for the diagnosis of asthma, an incidence of 0.5 per cent. He reports 9 additional cases of asthma and tuberculosis in 3 men between the ages of 27 and 40, 1 in a boy aged 5 and 5 in women between the ages of 24 and 41 who are under current observation. In this series of tuberculous patients asthma occurred less frequently than in the general population. In 34 discharged and 4 current patients asthma preceded tuberculosis, and in 2 discharged and 4 current patients tuberculosis

preceded asthma. There is no evidence in this group that tuberculosis predisposes to asthma or that asthma predisposes to tuberculosis. The claim that asthma is associated with the fibroid type of tuberculosis could not be substantiated. In 34 of the discharged patients and in the 9 current patients asthma had no unquestionably deleterious effect on tuberculosis. Correlation could not be made between the severity of asthma and the precedence of tuberculosis. Severe asthma tended to be associated with serious tuberculous endobronchial complications. There was no recognized instance of asthma of the tuberculo-allergic type, such as Urbach and Loew report.

Streptomycin in Experimental Tuberculosis.—Feldman and his co-workers inoculated 24 male guinea pigs by way of a superficial vein of the penis with 1 mg. moist weight of tubercle bacilli. The animals were divided into three groups as follows: 6 animals treated with streptomycin beginning at once and continuing for sixty days; 6 animals treated with streptomycin beginning on the fourth day after infection and continuing for 215 consecutive days; 12 animals were untreated controls. The daily amount of streptomycin administered per animal was 6 mg. given in four equal doses six hours apart. All untreated controls died within twenty-seven days. The duration of life of the animals in the two groups that received streptomycin was definitely extended. All treated animals eventually died, the last three hundred and forty-one days after the inoculation. Many had extensive tuberculous lesions. Morphologically there was impressive evidence that the residual lesions were in many instances no longer progressive but quiescent, healed or healing. The results demonstrated the ability of streptomycin to prolong the life of animals infected with a potentially rapidly lethal dose of tubercle bacilli. The tendency of the lesions to undergo fibrosis and the many instances in which signs of activity were missing in the organs of predilection indicate definitely that, anatomically, tuberculosis in guinea pigs may be profoundly altered in a favorable manner by streptomycin. An additional group of 29 male guinea pigs was infected with 0.5 mg. moist weight of tubercle bacilli. Treatment of 14 animals with streptomycin was started when the first infected animal died. Death of this animal occurred on the eleventh day after infection. The results of treatment in this experiment were definitely inferior to those observed when treatment was started earlier.

Sex Hormones in Allergic Disorders.—Hartman calls attention to the fact that allergic phenomena frequently cease or begin at puberty or the climacteric and that in the menacme they may be heightened during the menstrual or premenstrual period. At these times the usually satisfactory allergy regimens of elimination and desensitization may be relatively ineffective. The author lists the ways in which endocrine dysfunction may bring about clinical manifestations of allergy and analyzes the aberrations in pituitary-ovarian function in some allergic patients. Important factors determining the type of hormone therapy are: the time of appearance of clinical manifestations; the gonadotropic and steroid hormone inventory at that time; the presence of endogenous hormone sensitivity. In general, allergies appearing at puberty should receive the usual allergy regimen plus psychotherapy for the disturbed emotional state until some consistent hormonal pattern is established. Meno-

pausal onset or exacerbation is due to uninhibited pituitary overactivity, which may be inhibited by estrogen but also by androgen if bleeding is present. Satisfactory results were obtained in 84 per cent of patients in this group. Menstrual phenomena are usually due to transient estrogen deficiency, which can be prevented in 83 per cent of patients by a single large, properly timed injection of estrogen just before the expected period. Premenstrual exacerbations or appearances are usually associated with premenstrual tension, the fundamental difficulty being temporary excess of estrogen. This can be combated by oral methyltestosterone therapy during the postovulatory and premenstrual phase or by desensitization to estradiol.

Porokeratosis.—Jones and Smith report 2 cases of porokeratosis, an unusual and progressive cutaneous disease, in 1 youth aged 18 with congenital syphilis and in a boy aged 16 with acne of the face and back. Porokeratosis persists throughout life and is characterized by circinate or oval plaques composed of a hyperkeratotic linear border which progresses peripherally. There is a slender furrow running along the center of the peripheral wall, from which arises a keratotic ridge. Porokeratosis may be considered as of unknown origin, but a definite hereditary factor has been demonstrated repeatedly by reports of several cases of the disease occurring in one family. A possible relationship between porokeratosis and vitamin A deficiency is suggested. In both patients the onset of the disease occurred about the age of 12 years with slow progression of the lesions, which were clinically typical of the disease. It affects men three times as frequently as women. Porokeratosis should be classed with incurable dermatoses, because treatment has been unsatisfactory in the majority of the cases. Total excision of the lesion is the most reliable means of eliminating the disease, but this is suitable only in the early stages when lesions are small and few. Treatment was not attempted in the authors' cases.

Plantar Warts.—Blank treated 100 patients with plantar warts by exposing the verruca with a ring pad and salicylic acid ointment and destroying it with phenol and nitric acid used successively. Although indiscriminate chemical cauterization of these lesions is not without danger, no untoward reaction occurred in this series of cases. The number of applications varied from two to twelve, the average being six. Of the 88 patients on whom follow-up examinations were possible, all but 1 were free of clinical evidence of a verruca when the course of treatment was completed. The 1 patient who was a failure had had repeated inadequate surgical excision and electro-

desiccation over a four year period, with resulting scarring and distortion of the tissues. Of the 87 patients in whom the warts were obliterated by one course of treatment, 8 had a recurrence. Only 5 of the 8 submitted to repeated treatment, and in all of them a permanent cure was obtained.

Lipstick Cheilitis.—Zakon and his co-workers report 32 cases of cheilitis in women between the ages of 17 and 54 who were seen in one year of practice. Characteristic swelling and edema of both lips appeared after the patients had changed to a new type of lipstick, or the eruption appeared suddenly with continued use of the same brand over a period of months or years. The precipitating factor is the idiosyncrasy to and/or direct chemical irritation from the indelible dyes (bromofluoresceins). The diagnosis was made clinically, and treatment consisted of elimination of bromofluorescein dyes. A lipstick was substituted which did not contain dibromofluorescein, tribromofluorescein or tetrabromofluorescein. The patients' symptoms disappeared in an average period of two weeks. Photosensitization is to be considered as negligible. The use of a lipstick with a nonindelible dye is a practical, safe and rapid treatment and offers the solution of this frequent cosmetic problem.

Chronic Abdominal Pain in Women.—Best emphasizes that operation in the absence of detectable pelvic lesions is seldom justifiable in cases in which chronic pain is the presenting complaint. Surgery in such cases is meddlesome, ineffective and often mutilating; it may lead to a career of

repeated operative insults. Operation in the presence of obvious abnormality must be undertaken with caution and preceded by intensive pelvic study and observation. Not every pelvic deviation from normal is the cause of the patient's pain. Attention must be given to the environmental and psychic factors in the life of the patient. Pelvic surgery for prolapse, fibroids, ovarian tumors, ectopic pregnancy and cancer gives excellent results; pelvic surgery for chronic pain alone is seldom indicated and is often disappointing. Chronic parametritis, adnexitis, endometriosis, abdominal wall fibrositis, irritable colon and some displacements are the most frequent organic causes of chronic abdominopelvic pain in the adult woman.

Temporal Arteritis.—According to Hoyne, temporal arteritis characteristically affects aged white persons and causes severe head pains and generalized symptoms such as weakness, loss of weight, fever and mental confusion. He reports the history of a retired farmer, aged 75, who had this disorder. Temporal arteritis may be suspected and diagnosed by the presence of tortuous, nodular, hyperemic and exquisitely tender temporal arteries; the disease seems to be an inflammatory process. It is probably not a localized but rather a generalized polyarteritic disorder. Virtually all patients with temporal arteritis eventually recover after a prolonged illness. In this regard temporal arteritis seems to differ from periarteritis nodosa, which usually proves fatal within one year. There is no specific treatment. In some cases, including the one here reported, improvement has seemingly been accelerated by bilateral resection of the temporal arteries. This condition is undoubtedly commoner than heretofore regarded, and as the life expectancy of the population continues to increase, more and more of these cases of temporal arteritis will probably be encountered.

Congenitally Aplastic Ovaries.—Lissner and his associates review 25 cases of ovarian aplasia syndrome. Six of these have been verified by exploratory laparotomy or peritoneoscopy. In 15 cases tests were made for urinary gonadotropin excretion and all showed abnormally high titers. Five of these were among the 6 cases verified pathologically. There remained 9 cases in which the diagnosis may be regarded as presumptive but seems justified because of the characteristic clinical picture. This consists of primary amenorrhea in association with genital infantilism, short stature, stocky build with shield chest and sometimes webbed neck, cubitus valgus, and other congenital abnormalities. Severe sexual infantilism and primary amenorrhea existed in all but 2 of the 25 cases. One of these exceptions, a girl aged 22, had well developed breasts and had had a single spontaneous period five years before. In only 5 of the 25 patients did the height exceed 57 inches (145 cm.), and only 1 patient was over 61¼ inches (156 cm.) in height. As a rule, the stunting of growth was noticed early in childhood. The clinical differentiation from other types of dwarfism and sexual infantilism in females is discussed. It is particularly

important to distinguish this syndrome of congenital ovarian aplasia from primary pituitary infantilism. Adequate and prolonged estrogenic therapy is indicated and can be counted on, as a rule, to produce adequate mammary development, growth of sexual hair, more mature external genitalia and, when administered orally in cyclic fashion, regular periodic bleedings. These benefits bolster the patient's morale. The recognition of 25 cases from a single clinic suggests that this syndrome is not as rare as suggested by the few cases thus far reported.

Fresh and Dehydrated Food.—Deuel and Johnson made prolonged feeding tests on 8 men with fresh food diets and comparable diets made from dehydrated foods. Losses in body weight on the 2,000 calorie level were similar on the two types of diets. The acceptability as determined by ad libitum tests was equally good in the fresh and dehydrated foods. On the basis of studies on the protein and fat digestion and on the nitrogen values in urine and feces, it is concluded that the diets made from dehydrated foods may be equally as nutritious as those prepared from fresh foods.

Fat and General Nutrition.—Scheer and his associates say that earlier studies have shown beneficial effects on rats from the inclusion of liberal amounts of fat in the diet. Growth, resistance to undernutrition, physical capacity and reproductive performance were all improved on synthetic diets containing 10 to 40 per cent of fat, as compared with similar diets lacking fat. The present report includes data on the content of water, protein, fat, ash and calcium in the bodies of rats selected from these experiments. The authors found that in general the fat content of the body is not related to fat content of the diet; rats receiving diets with 20 per cent fat fed ad libitum have the highest content of body fat. Caloric restriction in weanlings or young adult rats results in relatively high water content and extremely low fat content; ash also increases in young adult rats. The greater body size on diets containing liberal amounts of fat as compared with fat-free diets is not the result solely of deposition of fat. The effects of varying fat content in the diet on resistance to undernutrition and on physical capacity are not the result of differences in gross body composition.

*Traumatic Diaphragmatic Hernia. L. E. Vin Zant and J. S. Hibbard.—p. 504.

Traumatic Diaphragmatic Hernia.—Vin Zant and Hibbard say that in many cases of herniation through a lacerated diaphragm diagnosis is not made until months after injury. A hernia should always be looked for in crushing injuries to the abdomen and perforating injuries of the lower part of the thorax and upper part of the abdomen. They report the case of a youth, aged 19, who was hospitalized because of nausea, vomiting and pain of seven days' duration in the epigastric region. At the age of 12 years he was struck by a car, and a door handle was embedded in his back. Four months later, shortly after wrestling, he complained of pain in the epigastric region and vomited. An appendectomy was performed. A year later, the same symptoms returned and he was operated on for obstruction of the bowel, but the site of the obstruction was not found. Transnasal duodenal suction and enterostomy completely relieved his obstruction. At the age of 17 he was hit in the right upper quadrant of the abdomen while playing football; there developed nausea and frequent vomiting, which were relieved by conservative therapy. Roentgen studies at this time revealed a diaphragmatic hernia which undoubtedly was the cause of his previous disability. Lacerations of the diaphragm are usually small, and stomach or colon herniations are most prone to strangulation. The high mortality of traumatic diaphragmatic hernia is due to the occurrence of intestinal obstruction and strangulation. Operative treatment should be employed early and not as a last resort.

Poliomyelitis.—Platou discusses some of the factors that deserve consideration in caring for a child with poliomyelitis. He agrees with Stimson that in the average spinal case a schedule of rest and relaxation, of proper nursing care and of measures to combat increased muscle tension should be put in the hands of well trained personnel. In addition to fever, prostration and toxemia, patients with bulbar involvement manifest dysphagia, nasal regurgitation, voice change, palatine weakness with lost gag reflex, pooling of mucus in the oropharynx and the airways, pulse changes, hypertension and pallor associated with varying degrees of cyanosis. In these cases psychologic reassurance, supervision of fluid and electro-

lyte balance and proper nutrition are important. Aspiration must be prevented by means of posture, suction and tracheotomy; the use of the respirator should be avoided except in the high spinal type. Oxygenation should receive careful attention. Avoidance of bladder and bowel retention, reduction of intracranial pressure, prophylaxis against infection and supportive measures are other factors that deserve attention in bulbar cases. The dramatic saving of life by means of suction, tracheotomy and oxygenation was impressive in a series of almost 400 seriously ill patients. The newer ideas in physical therapy continued to be meritorious. Also important were the round-the-clock vigilance of the physician and the expert service furnished by the nurse and physical therapist to conserve the physiologic functions necessary to life.

Muscular After Effects of Poliomyelitis.—According to Knapp the serious muscular after effects of poliomyelitis include shortening, weakness or paralysis of muscle and loss of muscular efficiency, often called incoordination. Muscle shortening must be combated at the earliest possible date, long before fibrosis has occurred. The author begins treatment immediately after the diagnosis has been made, even while the temperature is still elevated. The more vigorous the treatment of this symptom, the more likely it is to be successful. The essential element in the treatment of muscle shortening is motion. If the patient has sufficient muscular strength to allow him to perform voluntary motion against gravity, activity alone will often cause relaxation of the muscle. In patients who are too weak to carry out motion actively, the motion must be performed for them passively. If pain is a potent factor, and especially during the early stages of the disease, hot packs are a useful adjunct in the treatment of shortening of muscle. The packs to be effective should be so hot that the patient squirms. This is not a heat application in the true sense of the word; it is really a reflex stimulus. Among the drugs that have been used for relaxing muscular tension the author mentions prostigmine, curare, quinine and atropine. Muscular strength can be increased by producing hypertrophy in those muscles which still have innervation. The most effective method of causing hypertrophy of muscle fiber is the use of heavy resistance exercises, making the patient contract the muscle against a nearly maximal load. Nerve crushing or neurotripsy, introduced by Billig and Van Harreveld, is mentioned. With regard to the restoration of muscular efficiency, the author says that muscles work not independently but in combination with each other. Therefore, if the part is used in the manner which is desired, the various correlating muscles and neurons will learn to interact with each other to produce the action which has been practiced.

Heparin/Pitkin Menstruum in Thromboembolic Disease.—Loewe says that at the Jewish Hospital of Brooklyn more than 450 patients received thousands of subcutaneous deposits of heparin/Pitkin menstruum for intravascular disease. Of the 251 patients who received this treatment for the venous form of thromboembolic disease, 95 had had from one to six pulmonary embolizations prior to subcutaneous heparin therapy. There were 5 fatalities. Four occurred early in the series and served as an object lesson for standardizing and formulating the program of therapy and dosage schedules. As an offset to these failures there were 7 patients who had multiple pulmonary emboli despite venous ligation and who recovered after the subcutaneous heparin treatment. There were also 22 patients who were successfully treated with heparin in the Pitkin menstruum following single or multiple massive pulmonary embolizations without manifestation of peripheral vein involvement; these patients could not conceivably be subjects for ligation of the proximal vein. Subcutaneous heparin was successfully employed in 7 patients following failure of "dicumarol" therapy. Treatment of venous thromboembolic disease with subcutaneous heparin in the Pitkin menstruum was attended with lessened morbidity, prompt and rapid clinical improvement, and little or no residual edema. Exploratory studies in the field of prophylaxis and in the treatment of various arterial thrombotic disorders, including coronary artery thrombosis and peripheral vascular diseases, are sufficiently promising to justify further intensive investigations.

important to distinguish this syndrome of congenital ovarian aplasia from primary pituitary infantilism. Adequate and prolonged estrogenic therapy is indicated and can be counted on, as a rule, to produce adequate mammary development, growth of sexual hair, more mature external genitalia and, when administered orally in cyclic fashion, regular periodic bleedings. These benefits bolster the patient's morale. The recognition of 25 cases from a single clinic suggests that this syndrome is not as rare as suggested by the few cases thus far reported.

Fresh and Dehydrated Food.—Deuel and Johnson made prolonged feeding tests on 8 men with fresh food diets and comparable diets made from dehydrated foods. Losses in body weight on the 2,000 calorie level were similar on the two types of diets. The acceptability as determined by ad libitum tests was equally good in the fresh and dehydrated foods. On the basis of studies on the protein and fat digestion and on the nitrogen values in urine and feces, it is concluded that the diets made from dehydrated foods may be equally as nutritious as those prepared from fresh foods.

Fat and General Nutrition.—Scheer and his associates say that earlier studies have shown beneficial effects on rats from the inclusion of liberal amounts of fat in the diet. Growth, resistance to undernutrition, physical capacity and reproductive performance were all improved on synthetic diets containing 10 to 40 per cent of fat, as compared with similar diets lacking fat. The present report includes data on the content of water, protein, fat, ash and calcium in the bodies of rats selected from these experiments. The authors found that in general the fat content of the body is not related to fat content of the diet; rats receiving diets with 20 per cent fat fed ad libitum have the highest content of body fat. Caloric restriction in weanlings or young adult rats results in relatively high water content and extremely low fat content; ash also increases in young adult rats. The greater body size on diets containing liberal amounts of fat as compared with fat-free diets is not the result solely of deposition of fat. The effects of varying fat content in the diet on resistance to undernutrition and on physical capacity are not the result of differences in gross body composition.

Traumatic Diaphragmatic Hernia.—Vin Zant and Hibbard say that in many cases of herniation through a lacerated diaphragm diagnosis is not made until months after injury. A hernia should always be looked for in crushing injuries to the abdomen and perforating injuries of the lower part of the thorax and upper part of the abdomen. They report the case of a youth, aged 19, who was hospitalized because of nausea, vomiting and pain of seven days' duration in the epigastric region. At the age of 12 years he was struck by a car, and a door handle was embedded in his back. Four months later, shortly after wrestling, he complained of pain in the epigastric region and vomited. An appendectomy was performed. A year later, the same symptoms returned and he was operated on for obstruction of the bowel, but the site of the obstruction was not found. Transnasal duodenal suction and enterostomy completely relieved his obstruction. At the age of 17 he was hit in the right upper quadrant of the abdomen while playing football; there developed nausea and frequent vomiting, which were relieved by conservative therapy. Roentgen studies at this time revealed a diaphragmatic hernia which undoubtedly was the cause of his previous disability. Lacerations of the diaphragm are usually small, and stomach or colon herniations are most prone to strangulation. The high mortality of traumatic diaphragmatic hernia is due to the occurrence of intestinal obstruction and strangulation. Operative treatment should be employed early and not as a last resort.

Poliomyelitis.—Platou discusses some of the factors that deserve consideration in caring for a child with poliomyelitis. He agrees with Stimson that in the average spinal case a schedule of rest and relaxation, of proper nursing care and of measures to combat increased muscle tension should be put in the hands of well trained personnel. In addition to fever, prostration and toxemia, patients with bulbar involvement manifest dysphagia, nasal regurgitation, voice change, palatine weakness with lost gag reflex, pooling of mucus in the oropharynx and the airways, pulse changes, hypertension and pallor associated with varying degrees of cyanosis. In these cases psychologic reassurance, supervision of fluid and electro-

the use of a sphygmomanometer cuff. Adequate incisions were made to allow free escape of pus, and all sloughs were dissected out. Drainage was maintained by packing the wound open for forty-eight hours with gauze, which was impregnated in the first three groups with penicillin cream (100 units per gram) and in the fourth group with sterile soft paraffin. In the first group 40 patients were treated in the manner previously described and were given intramuscular penicillin in oil and beeswax, 250,000 units daily. The treatment of the 47 patients in the second group was exactly identical with that in the first group, except that the dosage of penicillin in oil and beeswax was reduced to 125,000 units daily. The third group consisted of 61 patients treated with intramuscular sodium penicillin in aqueous solution, 200,000 units daily. The 112 patients of the fourth group had the same operative treatment as those in the other groups, but penicillin was not administered parenterally or used as a local dressing. The end results were similar in all groups, that is, benefit was not obtained from postoperative parenteral administration of penicillin. Bone necrosis, necessitating sequestrectomy, occurred only in patients treated late. Many of these patients had had a fairly intensive course of penicillin before they were seen. The principle of the Bunyan bag was applied to the dressing of large superficial infections of the fingers. After incision and drainage, a sterile rubber finger-cot was rolled over the finger and fixed with adhesive to the base of the finger and 2 cc. of sodium penicillin in water, 10,000 units per cubic centimeter, was introduced under the adhesive band, with a syringe and needle, to flood the finger-cot. A gauze dressing was bandaged lightly over the finger-cot and left undisturbed for two days. On removal of the dressing the wound was clean, and healing took place rapidly thereafter. The use of penicillin-sulfathiazole powder as a postoperative dressing is to be condemned.

Meningitis Following Spinal Analgesia.—Davidson thinks that accounts of meningitis following spinal analgesia are infrequent because of "a natural reluctance to report what should be a preventable happening," but he believes that the conscientious recording of such cases is important, if only to emphasize the possible dangers of the method and keep in everyone's mind the importance of a rigid aseptic technic. The author reports 2 cases of meningitis due to *Pseudomonas aeruginosa* following spinal analgesia. One patient recovered after treatment with sulfamerazine; the other died. The source of the infection could not be traced. In a similar case the source was so-called sterile water in the operating theater.

Paludrine in Vivax Malaria.—Woodruff gives an account of 20 cases of benign tertian malarial relapses which were treated with "paludrine," N₁-p-chlorophenyl-N₃-isopropyl biguanide. In 15 cases of benign tertian malaria treated with a single dose of 100 mg. of "paludrine" on one day only, the response was slow in comparison with that obtained following standard treatment

for three days with quinine and followed by quinacrine. This single dosage of "paludrine" did, however, bring the attack under control. No toxic manifestations were noted during the period of six months in which 20 patients were receiving 100 mg. of "paludrine" weekly. During this period, however, 1 proved short term relapse of vivax malaria was encountered, and 3 possible clinical attacks were also reported. During the six months' period immediately following the six months of "paludrine" administration, 1 proved long term relapse and 1 possible clinical relapse were encountered. These results suggest that a single dose of 100 mg. of "paludrine" is a suboptimal dose in an acute attack. Doses of 100 mg. weekly occasionally fail to keep the blood sufficiently free from parasites to prevent short term relapses. This weekly dosage, continued for a period of six months, does not invariably prevent the occurrence of long term relapses when use of the drug is discontinued.

Granulomas Caused by Talc.—In their experiments on rats Saxén and Tuovinen used pure talc and also powders containing talc, such as two sulfonamide wound powders containing 35 and 33 per cent talcum powder, respectively. They also used a powdered sulfonamide drug without any other admixture. The animal experiments established that a small quantity of talc introduced into uninjured tissue is generally resorbed in a short time without leaving any traces, but a large quantity may cause considerable foreign body granulomas. Similar granulomas occur regularly in injured tissues into which talc is rubbed. In this case comparatively small quantities of talc cause granulomas which are preceded by purulent inflammations in the necrotic area. A chemically clean sulfonamide powder disappears from the animal tissue without causing histologic changes. Histories of 6 patients with foreign body granulomas are examined. The authors believe that contamination of the tissue with talc through a torn glove is a rare occurrence. Granulomas may easily develop if sulfonamide wound powders containing talc are introduced into the operative field. In certain rare circumstances even pure sulfonamide powder may give rise to granulomas.

Stenosis of Splenic Vein in Children. E. Grundler.—p. 50.

Bone Marrow Puncture for Diagnosis of Typhoid in Children.—At Rogge's clinic sternal puncture was done in 47 of 185 children with typhoid. Bacilli could be demonstrated in the sternal punctate in a much higher percentage of cases than was possible by blood culture. While blood culture yields bacilli as a rule only during the first week of the disease, sternal puncture does so practically throughout the entire course of the disease. Frequently the sternal punctate was the only reliable proof of the presence of typhoid. The author regards puncture of the sternum or tibia as an important diagnostic aid when typhoid is suspected in children.

Blood Coagulation in Children with Infectious Diseases.—Ströder and Karp review observations on 255 children up to 14 years of age. They found that in scarlet fever, measles, typhoid, paratyphoid, pulmonary tuberculosis and whooping cough the coagulation time is normal, even if these diseases appear in the hemorrhagic form. Diphtheria, particularly the toxic form, increases the blood coagulation time. The prothrombin time is subject to considerable changes even in healthy children, and the aforementioned infectious diseases did not increase it to abnormal values. Hypoprothrombinemia was observed in about half of the cases of intestinal infections, particularly in Flexner's dysentery. The hypoprothrombinemia that accompanied infectious disorders showed a certain parallelism with the clinical course. About a fourth of the infants with nutritional disturbances had hypoprothrombinemia, and the prothrombin times were highest in the severest nutritional disturbances. However, as in the intestinal infections of older children, the prothrombin time does not parallel the temperature changes and in both conditions it may persist after recovery. Prothrombin time and coagulation time may show conformity in toxic diphtheria but do not necessarily have to do this. The bleeding time was unchanged in the infectious diseases that were investigated.

 *Digitalis and Strophanthin Preparations Considered as Drugs Which Favor Action of Chemical Mediators: Their Action on Normal Myocardium, in Myocardial Insufficiency and in Diseases Different from Those of Circulatory Apparatus. D. Danielopolu.—p. 66.

Surgical Treatment of Mitral Stenosis.—According to Mahaim, narrowing of the left auroventricular orifice need not always be due to a stenosing defect of the mitral valve. It may be caused by a tumor-like polyp in the left auricle which increases with time and which may involve the mitral ring; it may even pass through the ring and be lodged occasionally in the left ventricle. The tumor is often myxomatous and has the tendency to produce peripheral myxomatous embolism. Angiocardiography may reveal a lacunar auricular picture which could be considered as a definite roentgenologic sign. Surgical removal of the mitral polyp would be the only treatment for this condition.

Contusion of the Heart.—Hedinger reports the occurrence of sudden death in a soldier aged 53, nine days after he was kicked on the chest by a horse. Death resulted from infarction of the anterior wall of the left ventricle and rupture after a traumatic, thrombosing, dissecting aneurysm of the descending branch of the left coronary artery. For three days after the accident the patient had no complaints and returned to his unit to do his usual work. The grave traumatic coronary injury was masked completely during this period. A prolonged period of control even in the absence of clinical symptoms is suggested to prevent late lesions in cases of severe thoracic trauma in which a contusion of the heart seems likely.

Mechanism of Action of Digitalis and Strophanthin.—The results of experiments with digitalis and strophanthin preparations carried out by Danielopolu on guinea pigs, dogs and frogs, as well as therapeutic trials on man, suggest that these drugs have a nonspecific action and a specific or toxic action. The nonspecific action consists in the inactivation of cholinesterase by promoting the action of acetylcholine and inactivation of the adrenolytic factors by promoting the action of sympathin. By their inactivating action on cholinesterase the digitalis and strophanthin preparations stimulate the secretion of epinephrine. In their effect on the adult myocardial fibers and on the vascular fibers the favorable action of the therapeutic doses of these drugs on the activity of sympathin surpasses their favorable action on the activity of acetylcholine; in the embryonal cardiac fiber the latter influence surpasses the former. With small doses the action is inverse. Both the specific and the nonspecific action may be exerted with any dose, but the former becomes evident only with high doses which are

not used for therapeutic purposes. Systolic arrest of the action of the heart is to be considered as an effect of the toxic action. Digitalis and strophanthin preparations exaggerate the excitability of the nervous centers by their inactivation of cholinesterase in promoting the action of acetylcholine. The drugs exaggerate the excitability of the cardiac nerves by increasing the excitability of the neurons and the sympathomimetic and parasympathomimetic reactivity of the myocardium. The drugs are stored not only in the myocardium but in all the tissues of the body. Occurrence of sudden death after big doses of strophanthin (Fränkel's method) is due to the accumulation of acetylcholine because of the inactivating action of the drug on cholinesterase. It might be possible to increase the dose of strophanthin in grave cases by combining it with atropine, as the latter prevents the parasympathomimetic action of acetylcholine. Certain faculties of the digitalis preparations may be corrected and strengthened with atropine and with physostigmine, but strophanthin should never be combined with physostigmine. Digitalis and strophanthin preparations are not exclusively cardiac tonics but vegetative drugs which can be useful whenever one wants to promote the action of sympathin and acetylcholine. The dosage of these drugs should be based on the determination of their inactivating action on cholinesterase.

Reanimation by Artificial Circulation.—Schwegk produced circulatory arrest in dogs by rapidly withdrawing the blood from the femoral artery. Under morphine-ether narcosis the blood pressure in the other femoral artery was recorded with a mercury manometer. Artificial restoration of the circulation was then performed by pumping the blood from the right jugular vein and by reinjecting the artificially arterialized blood into the femoral or carotid artery. A modified Gibson apparatus was used in these experiments. The results demonstrated that artificial blood perfusion of the entire animal is possible in principle. Respiration and heart action could be restored by artificial circulation up to fifteen minutes after clinical death. In addition to respiration the functioning of vasomotor centers was manifested by the occurrence of Traube-Hering waves. The term reanimation appeared justified in only 2 instances in which heart action and respiration continued spontaneously after artificial circulation was discontinued. The duration of "clinical death" in these instances was seven and five minutes, respectively. Pupillary, corneal and tendon reflexes returned. In the first instance the dog survived the experiment for twenty-six hours, in the second instance only for five hours, but consciousness was not restored completely. Reanimation of the heart may be obtained without difficulty. A complete reanimation of the central nervous system could not be achieved because of the irreparable damage in the cerebral cortical areas resulting from the circulatory arrest, which lasted in these instances for seven and eight minutes, respectively, from the moment in which the blood pressure reached the zero point.

Artificial circulation in man may be considered in cases in which temporary cardiac failure may be bridged some time before the definitely expected circulatory arrest, e. g., threatening arrest of heart action during surgical intervention.

"Dripping Nose" as Early Symptom of Hunger Edema.

—While in a concentration camp where hunger edema was prevalent, van der Hal noted that a constantly dripping nose, in the absence of any other sign of rhinitis, was often a sign of impending hunger edema. The dripping nose persisted after the hunger edema developed.

Corneal Changes During Treatment with Arsphenamine.—According to van Doormaal, treatment with arsphenamine preparations may cause serious corneal lesions. He describes the case of a man, aged 47, who, while being treated with arsphenamine and a bismuth compound for syphilis developed a severe dermatitis, conjunctivitis and bilateral corneal ulcers which perforated. The patient recovered very slowly from his dermatitis and became almost blind. Corneal lesions which develop during arsphenamine treatment usually but not always appear in the course of arsphenamine dermatitis.

Toxic Fulminant Laryngobronchitis (Malignant Pseudocroup). B. Söderling.—p. 1812.

Prognosis in Disseminated Sclerosis and Disseminated Encephalomyelitis.—Differential diagnosis in the initial stage of disseminated sclerosis and disseminated encephalomyelitis was used to judge prognosis. In the initial stage the diagnosis was disseminated sclerosis in 84 of Thygesen's 144 cases, disseminated encephalomyelitis in 29, probable disseminated sclerosis or disseminated encephalomyelitis in 31. On revision of the diagnosis after from eight to fifteen years the diagnosis disseminate encephalomyelitis could be upheld in only 17 of the 29 cases and typical disseminated sclerosis had developed in 7; 4 of the 17 died during the first year, the others were free from symptoms after the first year or year and a half. In 19 of the 31 cases the disorder developed as disseminated sclerosis, mostly of benign type, and in 12 the diagnosis of disseminated sclerosis or disseminated encephalomyelitis was excluded. Of the 110 patients with disseminated sclerosis, 14 were fully able to work and 13 partly able to work; in 52 there had been steady progression with early incapacity for work, and 31 were dead. Almost all the benign cases had an acute or subacute onset with total or partial remission during the first year, but the same manner of start and early course were also seen in fully half of the cases with persistent progression. In practically all cases with insidious start and steady progression during the first year the course was unfavorable. The prognosis seems to depend more on the spread of the underlying process than on the intensity of single symptoms and to be poorer in the cases with early ocular symptoms in connection with other symptoms and in those with

the early stage marked by incoordination of varied origin. Nystagmus as an isolated symptom has no prognostic significance. The course is more favorable in the older age group.

"Fericillin." W. Jadassohn, P. Boymond and H. Isler.—p. 737.

Retraction of Coagulum Elicited by Thrombocytes.—Fonio separated the plasma by centrifugation of blood which had been made uncoagulable with sodium citrate. The coagulation was then brought about by recalcification. By this new test tube method photographs could be taken from the plasma clot. Retraction of the plasma coagulum occurred provided that the plasma contained thrombocytes. There was no retraction if the plasma did not contain thrombocytes. A pronounced retraction occurred when an emulsion of thrombocytes in isotonic solution of sodium chloride was added to the plasma which did not contain thrombocytes. Addition of an extract of thrombocytes did not produce retraction, which occurs only when intact platelets are added. Addition of corpuscular elements which are foreign to the blood proved ineffective. A retractozyme could not be extracted from the retracted coagulum. The new retraction test was performed on a patient with thrombopenia whose thrombocyte count was 75,000. The plasma coagulum proved completely irretractable three times when the new test tube method was used, and the fourth time there was only a feeble indication of retraction. A normal retraction occurred in all the tests in which an emulsion of normal thrombocytes had been added to the patient's plasma. The degree of the retractility of the thrombopenic coagulum may be determined more exactly by testing the retraction on the thrombocyte containing citrated plasma than by the evaluation of the behavior of the blood coagulum alone.

*Clinical and Electroencephalographic Study of Hyperpyretic Convulsions. M. Neyroud.—p. 759.

Hyperpyretic Convulsions.—Neyroud reports the occurrence of hyperpyretic convulsions in 70 children, 39 boys and 31 girls between the ages of 2 months and 6½ years. The highest incidence of hyperpyretic convulsions was observed at the age of 18 months. History revealed the occurrence of non-epileptic convulsions in grandparents, parents or siblings of 67 patients and the occurrence of epileptic seizures in grandparents or parents of 5. There was also a high incidence of meningitis, particularly among the siblings of the patients. Eighteen patients were of an extremely nervous type, 14 presented behavior disorders and 6 had disturbances of speech. Four of 10 children aged over 3 years still had enuresis. In the majority of the patients the hyperpyretic convulsions may be considered as a common accident which has nothing to do with epilepsy, and the prognosis of which is favorable. They may be classed among the "essential convulsions" of infancy. These hyperpyretic convulsions may be caused by sudden disturbances of the cerebral circulation or ischemia followed by hyperemia, and they are closely connected with the sudden rise of temperature. However, the high incidence of hereditary and constitutional stigmas among the 70 patients justifies a certain caution in evaluating the late prognosis of hyperpyretic convulsions; in 2 of them the hyperpyretic convulsive syndrome was the first manifestation of epilepsy. The electroencephalogram will be of considerable aid in the differential diagnosis of hyperpyretic convulsions of children who are normal with regard to their nervous system from those who may be epileptic in the future. In 51 of the 70 patients the encephalogram revealed normal condition. In 9 patients the electroencephalogram was doubtful. Four encephalograms were definitely abnormal, and 2 presented epileptic patterns in children who not only had pure hyperpyretic convulsions but also manifested a definite clinical aspect of epilepsy.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

COMPLAINTS ALLEGEDLY DUE TO EXCESSIVE AMOUNTS OF ORANGE JUICE

To the Editor:—A number of patients who have spent the winter in Florida, and some who have spent only a few days or weeks, tell me that after they have had large quantities of orange juice a sort of toxic condition develops. They complain of vertigo, nausea, listlessness and dermatitis. This is not a matter of a few glasses of juice a day, but enormous quantities of it. At first I thought that perhaps this was partly imagination and partly due to the fact that they distended themselves too much, but I have heard this complaint over a period of six or eight years, and patients are still complaining. Is there any real basis for this condition, or have any reports appeared in the literature?

Allen H. Moore, M.D., Doylestown, Pa.

ANSWER:—It is unlikely that the symptoms complained of are the specific effect of orange juice, except in persons who are allergic to some constituent of orange juice. Other than that, toxic symptoms could be attributed only to excessive amounts of substances contained in oranges, substances which do not cause ill effects in usual quantities. This is improbable. None of the principal constituents, water, sugars, citric acid, ascorbic acid (vitamin C) and minerals, are known to cause specific symptoms in amounts which would be ingested under the conditions described. Water intoxication requires tremendous quantities. Ascorbic acid can be taken in amounts much greater than would be probable in the form of orange juice without symptoms. The same is true of the carbohydrate, minerals and organic acids. Experiments in which maintenance of complete saturation of the body with ascorbic acid was obtained by drinking quarts of orange juice daily were without such an effect except for some distaste for the orange juice. The nausea mentioned in the query may be the mild nausea or distaste commonly associated with the ingestion of large amounts of single foods, especially when accompanied by distention because of the bulk. In the absence of more details, an opinion on the nature of the dermatitis cannot be given. It would appear that the other symptoms are more probably the result of lack of acclimation, known to affect visitors to warm climates, aided perhaps by overindulgence in food and drink, than the specific effect of the orange juice. No references to such an effect of orange juice have been found.

THE IODINE NUMBER OF THE FATTY ACIDS

To the Editor:—What is the significance and manner of determination of the iodine number as applied to unsaturated fatty acids in allergic diseases of the skin? Please give one or two references. M.D., New York.

ANSWER:—Inasmuch as iodine is absorbed at the double bonds in the carbon chain, the iodine number of the fatty acids derived from blood is a measure of the relative degree of unsaturation of the fatty acids. (For preparation of fatty acids and determination of iodine number, *J. Biol. Chem.* 94:401, 1931-1932; *ibid.* 112:457, 1935-1936.)

This value in normal persons is, in the range of 100 to 120 depending on the age group. It has been found that in 50 to 80 per cent of patients with chronic eczematoid dermatitis, the iodine number of the serum fatty acid is below 100. No direct relation between allergy and the iodine number of the serum fatty acids has been observed; however, at times patients with chronic eczema appear to be benefited when fats rich in unsaturated fatty acids are added to the diet (*THE JOURNAL*, Dec. 7, 1946, p. 855; *Am. J. Dis. Child.* 73:1 [Jan.] 1947).

ARGYRIA

To the Editor:—BAL has been recommended for the elimination of arsenic from the tissues. Kindly inform me if it has been used successfully in the elimination of silver as in argyria?

Hugh Macdonald, M.D., Peoria, Ill.

ANSWER:—There appear to be no references in medical literature to the use of BAL in the treatment of argyria. However, on theoretic grounds beneficial results would not be expected, inasmuch as silver deposits in the skin are in metallic insoluble form and are not available for attraction to the sulfhydryl (SH) groups of the BAL compound.

TREATMENT OF IVY POISONING

To the Editor:—I recently had a case of poison ivy. The patient appeared in my office in the acute phase and I gave him an injection of "Sherman poison ivy-oak extract." I was subsequently severely criticized by the dermatologist, who claims that it should only be used as a prophylactic measure and not as treatment. Please comment.

M.D., New York.

ANSWER:—The practice of giving injections of poison ivy and poison oak extracts in the acute stage of the dermatitis is a common one and has been urged on the members of the medical profession by the manufacturers of such extracts; therefore, severe criticism should not be meted out to one who follows what was accepted as good practice. However, the injection of such extracts during the acute stage is of doubtful value inasmuch as immunization against any of the many sensitizing agents requires months and even years rather than hours. The Council on Pharmacy and Chemistry has recently revised its statement on rhus preparations to omit claims for use of these agents in treatment of ivy, oak or sumac dermatitis (*N. N. R.* 1947, pp. 15-16). Bathing the affected areas twice daily for fifteen minutes with potassium permanganate solution in the strength of 1:2,000 together with daily intravenous injections of sodium thiosulfate or calcium thiosulfate will probably be as effective as any other method of treatment known at the present time. Freezing the areas with ethyl chloride has been advised, but this should be carried out with a great deal of caution by the physician.

CASTRATION IN WOMEN FOLLOWING MASTECTOMY

To the Editor:—What is the present status of opinion concerning castration in the female as a preventive measure for possible recurrence of cancer of the breast following mastectomy? Is sterilization by roentgen radiation as effective as surgical oophorectomy in these cases? Would the use of estrogen therapy be contraindicated in the treatment of the artificial menopausal symptoms that might follow the foregoing procedure?

M.D., Philadelphia.

ANSWER:—Routine castration by irradiation or surgical operation following radical mastectomy is by no means a settled question. Many surgeons, however, are resorting to post-mastectomy castration, and they claim improved results for their cases. L. Halberstaedter and A. Hochman (*THE JOURNAL*, 131:810-816 [July 6] 1946) are convinced that interruption of estrogenic stimulation can effect objective and/or subjective improvement in breast cancer. J. S. Horsley (*Surgery* 15:590-601 [April] 1944) advocated the removal of both ovaries when performing radical operation for cancer of the breast in young women. G. W. Horsley (*Am. J. Surg.* 125:703-714 [June] 1947) observed a five year "cure" rate of 43.5 per cent in radical mastectomy cases without oophorectomy as compared with 76.5 per cent in those of the premenopausal period with oophorectomy. His results were much better than those obtained with roentgen ray castration, though the few patients treated with roentgen therapy showed better results than those without either irradiation or surgical castration. However, T. de Cholnoky (*THE JOURNAL*, 125:739 [July 8] 1944) maintains that it is not exactly known yet whether the elimination of ovarian function has the effect of reducing or enhancing carcinogenesis. It may, therefore, be hasty to advocate bilateral oophorectomy for all women in the premenopausal age with early breast cancer.

Estrogen therapy should not be given to overcome the menopausal symptoms following the removal of a breast except in women past 60 years of age who have metastases. In this group estrogens will relieve the pain due to metastases. In younger women the male hormone, testosterone propionate, should be used instead of estrogens to relieve the menopausal symptoms.

HAY FEVER IN HIGH SCHOOL BOYS

To the Editor:—I have two boys in high school who have hay fever and chronic nasal sinusitis. They have had the best allergists and nose and throat specialists available (without obtaining much relief). I have had psychologic tests on them in several universities and they rate superior, college material. What careers should I try to steer them into because of their respiratory weaknesses (which happen to be hereditary on both sides of the family)?

M.D., Tennessee.

ANSWER:—It would be a grievous error to steer these boys into any career for which they have no compelling urge. Other than staying away from extremely dusty occupations or those in which strong chemical fumes are involved, these boys are not handicapped for any career. On the other hand, if the facts of the case justified it, a change to a different climate might be advantageous. The boys should be given a free choice, with some judicious guidance on the part of the father. Above all, they should not be made to feel whatever handicap they may have.

RECURRENT ULCERS OF THE MOUTH

To the Editor:—For six months I have been treating a white man aged 21 for recurrent ulcers of the mouth, inside of lips and tongue. They are round, punched out, raised, gray, quite deep, and painful, and they bleed slightly on occasion. They last for about seven to ten days and recur at intervals of about two weeks to three months. This condition was first noticed three years ago in Alabama while he was in the Army. He has been completely worked up by smears and cultures, which have all been negative. He was treated with high potency vitamin therapy, ultra-violet and dyes of all kinds. However, the ulcers recur with fair regularity. These attacks are preceded by a bout of constipation. He has had a gastrointestinal series and proctoscopic examinations, and all were negative. There may be a psychiatric factor in this. Any help will be appreciated.

Harry Grodzicker, M.D., Brooklyn.

ANSWER:—Certain data which are not given would help in the diagnosis. It is assumed that the serologic test results and lungs are not abnormal. It would be of help to know whether the ulcers are preceded by vesicles or papules. An allergic cause would be improbable if there is a negative family, personal and contact history and angioneurotic edema of the face often coexists. A recurrent granulocytopenia could be excluded as a cause by blood counts. The description does not fit a dietary deficiency, lupoid or chemical origin or the lesions of erythema multiforme. The necrotic ulceromembranous ulceration of Vincent's infection seems unlikely from the location and bacteriologic data. Nerve lesions are improbable if the lesions are bilateral. Dissimilar metal fillings may produce an electric current, but the lesions are said to be rarely ulcerative. Herpes simplex may cause a gingivostomatitis with similar lesions, from a reflex or central cause, but the lips usually crust and there are often general symptoms.

The diagnosis is probably to be found under the general term, aphthous ulceration. One form is the common canker sore, which follows a vesicular onset; but the lesion most like that in the present case is called periaadenitis mucosa necrotica recurrens—it occurs on the tongue, lips and cheeks, lasts one to two weeks and follows a papular onset. The ulcers may be superficial or deep; they are painful and may bleed; they tend to recur at varying intervals.

The etiologic basis of aphthous ulcers is uncertain, with emotional, allergic, psychic, toxic and gastrointestinal causes being mentioned. The treatment is likewise indefinite. The mouth often is a mirror of the intestinal tract, and intestinal function is affected through innervation; a vagotonia sounds quite possible in this case.

It is suggested that the case be considered with the foregoing comments in mind and that specific therapy be applied if indicated. The following empiric measures may also be tried: one of the atropine-like drugs, either routinely before meals or during the constipation period, to interrupt the neurogenic influence; the use of a mild saline laxative at bedtime; continuance of a high vitamin intake in the form of a multivitamin concentrate plus 100 mg. of nicotinamide per day for several weeks, and applications of a 10 per cent solution of "butyn" (3-dibutylamino-propyl *p*-aminobenzoate sulfate) or "acriviolet" (a proprietary mixture of acriflavine and methylosaniline chloride).

Unless the foregoing suggestions prove definitely effective, it would be wise to have the man consult a neuropsychiatrist.

SCLERODERMA AND PREGNANCY

To the Editor:—A white woman aged 21 who had bilateral cervical sympathectomy two years ago for scleroderma, is now two months pregnant. Is pregnancy contraindicated? I should also like to know if Raynaud's disease is any contraindication to pregnancy.

John Shelton Reed, M.D., Kingsport, Tenn.

ANSWER:—Neither scleroderma nor Raynaud's disease contraindicates pregnancy. The progress of either disease is unaffected by child bearing. When scleroderma is sufficiently extensive it may interfere with free respiration. There may in such cases be mechanical difficulties with expansion upward of the gravid uterus.

"SPOON NAILS"

To the Editor:—A woman aged 40 worked in the San Francisco shipyards for two years during the war. She now has several finger nails bowed outward from the base up, and the other nails are showing signs of change. There is no hereditary or other pertinent history. Is there any treatment for this condition?

M.D., California.

ANSWER:—The description of the woman's nails leads to the supposition that the so-called "spoon nails" have developed; this is a dystrophy the etiologic and pathologic bases of which are variable, complex or obscure. Treatment is as a rule of no avail.

ETHYLENE DISULFONATE

To the Editor:—I would appreciate information about the treatment of allergic eczema in children with ethylene disulfonate, especially the percentages of successes and failures, and any undesirable by-effects.

Erwin Levi, M.D., New York.

ANSWER:—Ethylene disulfonate has been the subject of considerable controversy. First, there is some doubt that a compound of the alleged structure of ethylene disulfonate exists. In view of the enormous dilution, 10^{-16} (1 part in a million billion), it is impossible to analyze the commercial article ("allergosil" brand of ethylene disulphonate) and find anything but water. Second, the theoretic bases which underly the clinical utility of this compound are exceedingly doubtful. Third, the concomitant drug and dietary restrictions which are insisted on by the manufacturer seem totally irrational on the basis of present knowledge. But these points may be of practical importance, as they may explain some of the improvements that are occasionally seen after use of the article.

As far as its use in eczema in children is concerned, there have been favorable reports by Wasson (*Arch. Pediat.* 60:511-517 [Sept.] 1943 and Bartlett (*Arch. Pediat.* 61:311-316 [June] 1944). These reports are uncritical, and in neither are there adequate controls. Archibald (*Arch. Pediat.* 62:219-222 [May] 1945) came to the conclusion that any effect the product had was the same as that of distilled water. He pointed out that distilled water has been used in various allergic conditions on a nonspecific basis and with occasional good results, equal in percentage to those he obtained with ethylene disulfonate. In evaluating the result of treatment with this drug in eczemas or other allergic conditions, it should be recalled that the proponents do much more than merely administer the drug and also that a hypotonic solution injected intramuscularly will have certain nonspecific effects, which may occasionally yield a clinical result. Much of the pertinent literature is summarized in the report by the Council on Pharmacy and Chemistry in *THE JOURNAL*, Aug. 31, 1946, page 1495.

HONEY IN THE DIET IN HEART DISEASE

To the Editor:—I should like information on the striking effects of oral administration of bees' honey in aiding the therapy of heart diseases—organic and function in nature. For many years I have given my cardiac patients, instead of glucose injections intravenously two times a day, 15 Gm. of bees' honey. I can confirm from personal experience an excellent effect. Bees' honey is the best nourishment of heart muscle. What is the scientific basis of this striking effect? Please discuss the rationale of this therapy.

N. Costa, M.D., Herzlia, Palestine.

ANSWER:—There is no justification in the literature for this statement that bee's honey is the best nourishment of the heart. All glucose is good food for the myocardium. A high carbohydrate diet is practically always prescribed for patients with myocardial insufficiency. Further observations should be made on honey to determine whether it is better than any other substance.

Honey is defined by Shuette and Baldwin (*Food Research* 9:244, 1944) as the nectar and saccharine exudation of plants, gathered, modified and stored in the comb by the honeybee. Chemically it is a natural concentrated unrefined syrup of invert sugar and flavored according to the floral source. The main component is 75 to 80 per cent invert sugar, a conversion product of sucrose. The minor components are organic acids, pigments, nitrogen-containing components or compounds and pollen. Seven members of the B vitamin complex (particularly nicotinic acid and pantothenic acid, riboflavin, pyridoxine and thiamine) and vitamin C (ascorbic acid) have been identified in honey. There are small amounts of iron, copper, sodium, potassium, magnesium, calcium, manganese and phosphorus, all of which have been shown to be essential to good nutrition in animals. Commercial processes for clarifying reduce the vitamin content 33 to 50 per cent. Honey has been used as a levulose tolerance test of liver function.

Glucose is as effective as any monosaccharide, and invert sugar is normally changed to glucose in the liver. Fructose is considered to be better at glycogen formation than glucose; galactose is less so. Glucose when injected is absorbed and causes an increase in liver glycogen. Some is converted to muscle glycogen, and some is oxidized. Fructose may be converted slowly to glucose in muscle. The only sugar that may be directly oxidized in the muscle is d-glucose (dextrose). The usefulness of any carbohydrate, therefore, depends on the ease with which it is converted into d-glucose.

Honey is a good source of carbohydrate and would be rational in the dietary and dietotherapy of cardiac patients manifesting myocardial insufficiency.

The vitamins, particularly nicotinic acid, and the minerals may contribute some to the nutritive value of honey over that of ordinary glucose. These considerations might give some scientific basis for the observation, but the observations should be confirmed before discoursing on the theoretic possibilities.

ASTHENOPIA AND CONTACT LENSES

To the Editor:—A patient has a high refractive error, otherwise his eyes are organically sound. He feels comfortable with his present glasses and is able to read and do other close eye work for many hours without undue fatigue of the eyes. However, after an hour or so of driving his car or witnessing a double feature movie he feels a definite tightening of the muscles of the eyeball. This progresses so that at the end of two or three hours his eyes feel like "tightened cords." Usually this tightness recedes as he rests his eyes. However, occasionally a severe headache and pain in the eyeballs result. The patient has noticed this trouble for the past eight years. Increase in the trouble has simultaneously progressed with the increase in the refractive error, as evidenced by the 4 successive prescriptions for glasses. He has been under the care of competent ophthalmologists. The question arises whether this "asthenopia," if it can be so called, can be corrected by properly prescribed contact lenses. The patient's work necessitates a considerable amount of driving.

Chester C. Burski, M.D., Chippewa Falls, Wis.

ANSWER:—Contact lens are recommended and being used in keratoconus and other conditions characterized by irregular corneal astigmatism, in ametropia, for corneal protection in lagophthalmos, trichiasis and ectropion, in high unilateral myopia, in unilateral aphakia, in albinism and coloboma of the iris. They are useful as a substitute for spectacles in sports, as football and swimming, and for cosmetic purposes by actors and actresses.

Contact lens will frequently allow normal vision when this is not possible with ordinary spectacles, but their most enthusiastic advocates do not recommend them for the relief of asthenopia. They are considerably more troublesome than ordinary spectacles, and probably less than 70 per cent of those fitted can wear them for long periods with complete satisfaction. This is particularly true of those who do not absolutely require this type of correction.

In that this patient can do close work for long periods without difficulty, it seems likely that the refractive error is properly corrected. Investigation should be directed toward determination of the muscle balance, duction power, the presence of induced vertical prism in his spectacles and their centration. The cause of the asthenopia should be determined and corrected.

DESIGNATION AND RELATIVE FREQUENCY OF BLOOD GROUPS

To the Editor:—How do the A, B, AB and O blood groups correspond to the old style groups of 1, 2, 3 and 4? Give relative rarity of groups A, B, AB and O in per cent of general population. M.D., Ohio.

ANSWER:—The use of letters for the blood groupings was first suggested by Landsteiner in 1901. Jansky (1907) suggested groups 1, 2, 3 and 4 corresponding with the frequency of the blood groups, whereas Moss in 1910 reversed the numbers. For this reason some confusion resulted in the use of the latter two systems. Most of the hospitals in the United States are using the Landsteiner system and have discarded the Jansky or Moss nomenclature. Such a step was recommended by the Public Health Committee of the League of Nations, and it is known as the international nomenclature.

The following table gives the corresponding groups and the relative frequency in per cent of the general population:

	Blood Groups			
	O	A	B	AB
International	1	2	3	4
Jansky	4	3	2	1
Moss	4	3	2	1
Percentage distribution	45	43	8	4

MEDICATION FOR PINWORM DURING PREGNANCY

To the Editor:—Is it safe to use the usual pinworm medication in pregnancy?
Mary L. Rosenstiel, M.D., Freeport, Ill.

ANSWER:—Yes, it is safe to give the usual medication for pinworm (*Oxyuris vermicularis*) in pregnancy. Exceedingly free elimination is necessary, but violent purging of the bowel should be avoided to protect the products of gestation. Hexylresorcinol is an efficient medicament. The adult dose is one 0.2 Gm. pill, not to be chewed or crushed. A package for a single complete treatment is supplied in one vial, containing five of the 0.2 Gm. pills, taken successively until the desired result is obtained.

A DIAGNOSTIC PROBLEM

To the Editor:—A white man aged 54 came to me about three months ago with complaints of acute stomatitis and conjunctivitis. The condition started suddenly with nausea, a chill and intense burning and smarting of the eyes with a profuse mucous discharge, stuffiness of the nose, sore throat and intensely tender tongue and mouth. Examination revealed the following: The temperature was 100 F. orally, and there were intense conjunctivitis and blepharitis; nasal congestion; intense glossitis and cheilitis, and large ulcers in the buccal mucosa with a heavy white exudate. The roof of the mouth and the pharynx were very red, and there were many different sized blebs, some of which were full of blood-tinged fluid. The gums were sore and swollen, and the angles of the mouth were tender. Red and white blood count, sedimentation rate, Wassermann and agglutination tests and urinalysis all were negative. The man had felt well until the night before, when he was attending a business meeting. He said that his eyes started to burn and discharge; his lips and gums began to swell until he had to take his teeth out. He had had nothing out of the ordinary to eat, and he does not drink or smoke. He has had three such attacks at intervals of four to six weeks during the last four months. The condition has run a course of about ten days previously and cleared up spontaneously. I have given penicillin and "pyribenzamine" but am not convinced that they do any good.

Leo R. Hawkes, M.D., Preston, Idaho.

ANSWER:—The history and observations in this interesting case might be resolved into a more exact restudy of some of the component parts as stated. First, have the patient keep a written record of his food intake, stating the quantities et cetera. All oral and parenteral medicaments should likewise be included. Second, make a detailed allergic study and analysis. Third, obtain appropriate smears and cultures of the lesions of the oral mucous membrane. Fourth, have a review of the oral mucosa by a specialist in oral medicine.

The grand summary of all these observations will lead to the final common path of the ultimate line of therapy.

INCREASING PATIENT'S TOLERANCE TO PENICILLIN

To the Editor:—I have attempted to treat a patient with chronic purulent bronchitis by penicillin aerosol; unfortunately, he has shown a pronounced sensitivity to the drug. I tried another type of penicillin by another manufacturer in the hope of avoiding reactions, but he manifested similar reactions to the second type of drug. The patient is reluctant to try another type of penicillin. I, too, hesitate to subject him to the manifestations, severe shortness of breath and a constrictive tightness in the chest, that followed the use of the drug. Since he already has some strain on the right side of the heart as a result of a long-continued pulmonary condition, I consider that further trials would be dangerous. Would it be possible to give him skin tests with the various types of penicillin by different manufacturers, using the patch test? If this is feasible, I should like a description of a method for preparing and reading such patch tests.

Louis V. Blum, M.D., Baltimore.

ANSWER:—If a patient has become sensitized to penicillin he will react to all samples of the antibiotic. It has been shown that sensitization is due to penicillin itself and not to any impurities contained in the product. It has been reported recently (Peck, S. M.; Siegal, S., and Bergamini, R.: Successful Desensitization in Penicillin Sensitivity, *THE JOURNAL*, August 30, p. 1546) that the repeated injection of small amounts of penicillin three times a week will increase the patient's tolerance to the antibiotic so that repeated small doses of 20,000 to 30,000 units may be given without reaction. The initial desensitizing dose recommended was 400 units, and the dose was doubled every three days until the patient tolerated doses as high as 20,000 units at a time. Skin tests with crystalline penicillin can be carried out in the usual manner. Patch tests are unnecessary.

NEUROLOGIC SYMPTOMS FOLLOWING INJECTION OF MERCURIAL

To the Editor:—The answer on page 396, *The Journal*, Oct. 11, 1947, on the subject, "Neurologic Symptoms Following Injection of Mercurial," the authority responsible ignores the systemic "mercuraphylline injection, now marketed as . . . itself to a discussion of the sciatic nerve an . . . Since I have observed a similar reaction in a patient to whom I was administering "mercuripurin" intravenously, this anatomic reply to the problem seems inadequate.

My patient was receiving weekly intravenous injection of "mercuripurin" 2 cc. Approximately two hours following each injection there regularly developed numbness, tingling and severe cramps in the lower part of the legs and in the feet. These symptoms persisted on each occasion for almost twenty-four hours. After four reactions, all of increasing severity, I discontinued administration of the drug. Diuresis had been profuse and adequate. There was no ascertainable neurologic residual.

This case, together with that of the earlier correspondent, indicates that the problem is more a true reaction to the drug than an involvement of the sciatic nerve.

PROPHYLACTIC USE OF INFLUENZA VIRUS VACCINE

An Instance of Inadequate Protection Against Influenza A

ARIE C. VAN RAVENSWAAY, M.D.
Boonville, Mo.

The development of a method for the prevention of infections with influenza A and B virus was one of the important projects undertaken during the recent war by the Commission on Influenza, under the direction of the Surgeon General, United States Army. This effort culminated in the mass production of a vaccine consisting of formaldehyde-inactivated strains of influenza virus, types A and B, and its large scale use in the United States Army. At present this vaccine is commercially available for civilian use and is being utilized widely as a prophylactic agent for virus influenza. The widespread acceptance of this procedure is a commentary on the excellence of the medical research conducted under official direction during World War II. There are, however, certain difficulties in evaluating prophylactic measures for diseases such as virus influenza. The reported clinical studies on which the presently accepted preventive value of this method is based, while impressive, may not accurately foretell results which will be obtained in conditions not encountered in the original studies.

It is not the purpose of this report to deny the value of the prophylactic use of influenza virus vaccine. Sufficient amply documented instances of its effectiveness are in the literature to indicate otherwise. The incident to be described in which the procedure was essentially a failure is reported to indicate the need for further study of the applications and limitations of the method and of the vaccine now available for use.

On Dec. 18, 1946, 237 of 527 cadets at Kemper Military School, Boonville, Mo., received 1 cc. of influenza virus vaccine procured by special order from Eli Lilly & Company and shipped from their Kansas City depot. The material was refrigerated from the time of arrival until its administration twenty-four hours later. Parents of all cadets had previously been circularized, and the group receiving the vaccine was selected on the basis of parental approval or disapproval after the exclusion of a small group because of previous allergic manifestations. The age group involved ranged from 14 to 18 years. No evidence is apparent that the selection of the treated group was influenced by age or by any other factor except the desire of the parent.

During the remaining weeks of 1946 and until mid-February 1947, relatively little respiratory disease was

observed in the cadet corps. Those instances seen were characterized by a mild pharyngitis, minimal malaise and fever and a short course. On February 15, however, an outbreak appeared, characterized by sudden onset, rather severe constitutional symptoms (fever, malaise, generalized aching) and but little evidence of exudative rhinitis, pharyngitis or bronchitis. The clinical appearance of these cases was considered to be typical of virus influenza. At this same time similar epidemics were appearing in other schools and communities in central Missouri. The epidemic reached its peak on February 24 with the admission of 27 patients (table 2). The incidence then dropped sharply, and on March 1 admissions for disease of the upper respiratory tract reached the level before the epidemic. During the period from February 15 to March 1, inclusive, 48 patients were admitted for hospitalization in the school dispensary from the vaccinated group of 237 cadets and 79 from the unvaccinated group of 284 cadets. This represents an incidence of 20.2 per cent from the immunized group and 27.8 per cent from the nonimmunized group. All patients admitted either were febrile or became febrile during their period of hospitalization. No useful information is available regarding the less severe infections not requiring hospitalization which are known to have occurred in considerable number. Analysis of the average duration of the febrile period and the average maximum temperatures in the immunized and nonimmunized groups gave information of no apparent significance. This is summarized in table 3.

Samples of blood were collected during the febrile period and after an interval of two weeks from 3 cadets who had not received prophylactic immunization and from 2 cadets who had been so immunized. Through Drs. M. H. Mothersill and N. M. Powell of Eli Lilly & Company these were titrated against living strains of influenza A and B virus, erythrocytes being used as an indicator. The results of these titrations are summarized in table 1. Failure to agglutinate erythrocytes is considered to indicate neutralization of the virus. In all 5 subjects the serum collected during convalescence possessed increased antibody titers against influenza A. In all except 1 case this increase was well defined. In contrast, in all 5 cases there appeared to be a slightly decreased antibody activity against influenza B in the convalescent serum. These observations are considered as sufficient evidence to establish the etiology of the outbreak as influenza A virus.

While the number of cases on which serologic studies were done is small, it is of interest that the initial specimens of serum from the 2 cadets who had received immunization contained substantially higher antibody

titers than those from the unimmunized 3. There appears to be no reason for assuming that this increased titer did not result from the immunization and provides evidence that the vaccine as administered was potent. Similarly, it is of interest that the antibody titers in the convalescent serums from the unimmunized do not exceed the values in the initial specimens from the immunized cadets. In this group of 5 persons it would appear that circulating antibodies were produced as effectively by the vaccine as by the disease.

COMMENT

Speculation as to the reason for the comparative failure of immunization in this group involves the mass of evidence on which influenza vaccination has been developed, and an elaborate discussion seems inappropriate for this report. A few points will be mentioned briefly. Differences of opinion have been expressed

vaccination is considerably longer than a few months when vaccine of a suitable potency is used."

Hirst, Plummer and Friedewald^{1a} have considered the relationship of the incidence of influenza in the general population to the degree of protection afforded a vaccinated group and stated, "There are good grounds for believing that an increased general attack rate of influenza would be accompanied by a smaller degree of difference of incidence between vaccinated and normal population." This is mentioned because the attack rates in the outbreak concerned in this communication were 20 per cent (vaccinated) and 28 per cent (unvaccinated), in comparison with the 2.2 per cent (vaccinated) and 7.1 per cent (unvaccinated) incidence described in the reports of vaccination in the epidemic of 1943-1944.^{1c}

Salk and Francis,^{1c} however, did not agree with this opinion of Hirst and co-workers, and stated, "Con-

regarding the composition and concentration of the vaccine and regarding the duration of its effectiveness.¹ In the preliminary report (1944) of the Members of the Commission on Influenza, Army Epidemiological Board,^{1b} evidence was presented that a high reduction in attack rate persisted for not more than six weeks following vaccination. The epidemic reported in this communication began approximately eight and one-half weeks following vaccination. In a recent review of the problem (1946) Salk and Francis^{1c} stated, "Both direct and indirect evidence is available to support the contention that the duration of effectiveness of influenza

is considerably longer than a few months when vaccine of a suitable potency is used."

Finally, mention should be made of the study of vaccination for influenza conducted at the University of California by Eaton and Meiklejohn,^{1d} in which influenza began four to five weeks after inoculation and in which vaccination proved as ineffective as at Kemper Military School. Attack rates were low and the inferior results of vaccination were explained in part on antigenic differences between the infecting strains of virus and those composing the vaccine. To me this appears the most likely explanation of the failure of vaccination at Kemper Military School. The relative merits of influenza virus vaccine produced by different pharmaceutical houses is a frequent subject for discussion. It is not general knowledge that the National Institute of

Health of the United States Public Health Service specifies the strain composition of these vaccines. Undoubtedly, the National Institute of Health is studying the epidemic of last winter with the aim of improving future vaccines.

SUMMARY

An incident is presented in which an outbreak of type A virus influenza occurred in a military preparatory school population of 521 cadets in which approximately 45 per cent had received immunization with influenza virus vaccine fifty-eight days before the outbreak of the epidemic. The reduction in incidence in the immunized group as compared with the non-immunized group, while apparently statistically significant, was insufficient to justify the use of the procedure.

CONCLUSION

Further critical study is necessary to define the application and limitations of influenza virus vaccine as a prophylactic agent.

ADDENDUM

Since the preparation of this paper other reports relating similar experiences have appeared. Furthermore, it has been shown that the strain of influenza A prevalent during the winter of 1946-1947 is quite dissimilar antigenically from those contained in the influenza virus vaccine available at that time. Vaccine now available contains this strain, which has been designated as FM-1. Reference is made to an editorial, "Influenza," and to "Medical Progress: Influenza" by John H. Dingle, both appearing in the Dec. 4, 1947 issue of the *New England Journal of Medicine*.

Vaccination of man against epidemic influenza has given promising results in controlled studies during the past few years. Whereas earlier experiments yielded suggestive, equivocal or negative data, the development of vaccines prepared by various means from allantoic fluid infected with influenza virus led to the demonstration of definite protective effects by such preparations both under conditions of epidemic¹ and experimental exposure of vaccinated persons to influenza virus.² Thus the reports of the members of the Commission on Influenza of the Army Epidemiological Board indicated a reduction in the incidence of the disease of about 70 per cent in the influenza A epidemic of 1943¹ and of 90 to 95 per cent in the influenza B outbreak of 1945.³

Encouraging as these results were, reservations had to be made because of proved antigenic differences between various strains of influenza viruses of either type. Such differences were readily demonstrable in the animal experiment for both influenza A⁴ and B,⁵ and also by the Hirst technic of inhibition of hemagglutination.⁶ The role of these antigenic differences in problems of diagnosis and prophylaxis of the disease appeared to be of minor importance in earlier studies

Technical assistance was given by Mrs. Leone S. St. Vincent, Mrs. Evelyn B. Rosenberg and Mrs. Leontine L. Guthrie.

The work described in this paper was aided by the Office of Naval Research and the United States Public Health Service.

and discuss these difficulties as illustrated by the study of an influenza outbreak in a large boarding school for boys.

EPIDEMIOLOGIC AND CLINICAL DATA

Early in March 1947 an epidemic of influenza type A occurred in a school for boys in New Jersey. The institution had 521 students enrolled at the time of the outbreak. Observed cases of the disease amounted to 278, or 53 per cent of the student body, before the epidemic had run its course. Of this number 183, or 35 per cent, were admitted to the infirmary, whereas 95, or 18 per cent of the student body, although given a diagnosis of influenza on clinical grounds, were not considered sufficiently ill to require admission.

At first it appeared that the disease had been introduced from another boys' school whose student population had recently recovered from a similar epidemic. A group of about 25 students had come down to the school in New Jersey for a basketball game on March 1. The first cases of the outbreak were considered to have occurred on March 2, a time compatible with the known incubation period of influenzal infection. However, following further investigation, it became apparent that 4 cases of disease of the upper respiratory tract which appeared similar in nature to the epidemic illness had occurred during the last week of February. Serologic tests done subsequently strongly suggested that at least 3 of these cases must be counted as the first overt cases of the outbreak.

The disease assumed epidemic proportions on March 2, with 7 patients admitted to the infirmary. On the following three days there were 21, 14 and 24 admissions, respectively. The peak of the epidemic was reached on March 6 and 7 with 31 and 32 cases, respectively. After this time the number of patients admitted to the infirmary fell off until spring vacation began, March 19. Thus the outbreak showed the rapid rise and fall so familiar in institutional epidemics of influenza.

The epidemic disease appeared simultaneously in a number of widely separated dormitories on the campus. On the first day four of the houses were affected. The following day saw admissions from all but three of the twelve dormitories. Two of these three had cases on the third day and the last on the fourth day after onset of the epidemic.

The epidemic was of unusual interest inasmuch as 88 per cent of the students had been vaccinated early in December 1946 with a commercial influenza vaccine

of combined types A and B. Of those who had received the vaccine, 54 per cent were considered to have been affected either moderately (admission to infirmary) or mildly (confinement to dormitory), whereas 49 per cent of the small group of students who were not vaccinated became ill. Of the vaccinated, 36 per cent had cases of moderate and 18 per cent had cases of mild disease. The corresponding figures for the nonvaccinated group were 30 and 19 per cent, respectively. Table 1 summarizes these data. It appears, then, that there was no difference between the vaccinated and nonvaccinated students as to susceptibility to the disease.

The illness, in general, was mild, and again no significant differences could be established between the vaccinated and nonvaccinated students. The chief complaints consisted of headache, fatigue, sore throat, cough, general aches and pains and pains in the chest. The average maximal height of temperature was 101 F. in both groups. The temperature rose to 105 F. in 1 person but in 34 per cent of the patients never went over 100 F. The period of elevated temperature varied from one to four days, with an average of 1.9 in the vaccinated and of 2.8 in the nonvaccinated groups. The significance of this difference is questionable, since the nonvaccinated group consisted of only a small number of students. The average time spent in the infirmary was 3.7 and 4.3 days, respectively. These data are included in table 1. Other physical signs noted consisted of flushed face and injection of the mucous membranes of nose, mouth and throat. The local glands in the region of the neck were only slightly enlarged. Injection of the conjunctivas was noted in the majority of the patients. Cyanosis of the lips was noted in many. No abnormalities in the chest were observed except for very occasional transient rales. Complications were few in number, the most important being bilateral otitis media, edema of the throat and early pneumonia of the lower lobe of the left lung with roentgen findings, each in 1 different patient. White blood cell counts taken during the acute phase of the disease were normal in the main, except for a few which showed a count below 5,000. Few of the patients seen were in any great distress, and for the most part they were only slightly incapacitated.

* Titer is the fold reduction of virus activity by a given dilution of specific serum.

LABORATORY STUDIES

Isolation of Virus.—The etiology of the epidemic was established both by isolation of the virus and by serologic means. Several strains of influenza virus, type A, were isolated from throat washings which had been treated with penicillin (500 units per cubic centimeter) and streptomycin (100 units per cubic centimeter) before inoculation into chick embryos by the amniotic route. On first passage, virus was present mainly in the amniotic fluids, although in 1 instance virus was found predominantly in the allantoic fluid. On second

amniotic passage, the viruses grew freely in the allantoic sacs and no hemagglutination was noted in the amniotic fluids. Some strains agglutinated guinea pig red cells to a titer eight to thirty-two times higher than that obtained with chicken red cells in the early passages. These data are suggestive of the O or

Chart 1.—Influenza at school L. Frequency distribution of titers in red cell agglutination inhibition test with acute and convalescent serums. The dotted lines represent the acute phase serums and the solid lines the convalescent phase serums.

“original” form of influenza virus as described by Burnet⁷ or of the intermediate forms⁸ which, although showing higher agglutination titers with guinea pig red cells than with the chicken erythrocytes (an O phase characteristic), grow well in the allantoic sac (a D phase feature).

One of the isolated strains of virus has been studied more extensively. It has not been sufficiently adapted as yet to mice by the intranasal route to produce infection in high dilution, nor has it shown any toxic activity⁹ when injected intravenously into mice. The lack of toxicity appears consistent with the general mildness of the disease caused by the virus.

The isolated strain of virus was found to be antigenically only remotely related to the PR8 and Weiss strains incorporated in the vaccine used. These strain differences were clearly demonstrated by the use of immune chicken serums¹⁰ as shown in table 2. The hemagglutination inhibition test employing progressively increasing dilutions of virus with constant dilutions of serum was used. The titers in this table represent the factors by which the hemagglutinins of homologous and heterologous viruses were reduced by each serum. It can be seen that the homologous neutralization was always best and that cross neutralization occurred only in the low concentrations of heterologous viruses.

Serologic Studies.—Serums collected from the subjects during and after the outbreak were tested for influenza virus antibodies by means of the hemagglutination inhibition and complement fixation tests. For the hemagglutination inhibition test, the technic already mentioned was employed, a constant dilution of serum (usually 1:80) being used. The “titer” of serum was defined as the ratio of the hemagglutinin end point in saline solution to the hemagglutinin end point in serum (1:80). Thus, if the former end point was 1:1,024, and the latter 1:16, the titer of serum was given as 64.

The details of the method have been described elsewhere.¹⁰ Tests were performed with the PR8, Weiss and L₂47 strains of influenza A virus and, on a smaller scale, with the Lee strain of influenza B virus. Chart 1 shows the distribution of serum titers to the three strains of influenza A virus in 25 paired specimens of acute and convalescent serum. The acute phase serums were collected on the first day of the disease and the convalescent phase serums ten days later. As can be seen in the chart the majority of the acute phase serums contained high titers of antibody to the PR8 strain (32 or higher). This indicated that the vaccine given three months prior to the outbreak had been of satisfactory potency, a fact which was confirmed by the assay in mice of a sample of the vaccine used. The titers against the Weiss strain were decidedly lower. None of the serums showed a high titer to the epidemic virus, the L₂47 strain. The vaccine failed, therefore, to produce sufficiently high and persisting antibody levels to the epidemic virus. This observation is in agreement with the antigenic relationship between the PR8 and L₂47 strains as demonstrated in the neutralization tests with chicken immune serums. The antigenic differences combined with the absence of cross reacting antibodies to the epidemic virus in the blood of the students offers a reasonable explanation for the failure of the vaccination to protect this group.

On comparison of the titers of convalescent serums with those found in the specimens of acute serum, it becomes obvious that the most pronounced rise in antibody level occurred to the L₂47 virus and that there was only a slight increase in titer in the convalescent serums when tested with the PR8 and Weiss viruses. The fact that most persons had high titers to the PR8 virus in the specimen of acute phase serum may account for the failure to demonstrate significant rises in antibodies to this virus in many of the convalescent serums.

Complement fixation tests were conducted according to the method described previously.¹¹ The antigens employed consisted of either the 600 S component,

which corresponds to the virus particle, or the 30 S fraction, corresponding to the soluble antigen, which reacts type specifically but not strain specifically in the

complement fixation test.¹² Both preparations were derived from allantoic fluids infected with the PR8 strain. The distribution of titers in the 25 cases during the acute and convalescent stage is shown in chart 2. As can be seen in the chart, many of the acute phase serums which reacted strongly in the inhibition test with PR8 virus exhibited also some reactivity with the 600 S antigen. None of the acute serums fixed complement in the presence of the 30 S antigen. There was a definite rise in antibody levels in the convalescent serums to both antigens. Twenty-two of the second specimens had titers of 1:16 or higher to the 600 S component, and 20 showed similar titers to the soluble antigen. The remaining cases showed some, although less pronounced, reactions.

A comparison of the diagnostic value of the various technics used in these studies is shown in table 3. This table is based on the number of diagnostic positive reactions obtained with the hemagglutination inhibition and the complement fixation tests. A positive result is considered a threefold or greater rise in antibodies, whereas a twofold increase in titer is considered doubtful or suggestive evidence of infection. The table shows that the most sensitive procedures were the hemagglutination inhibition with the epidemic virus, the L₂47

TABLE 3.—Number of Positive, Doubtful and Negative Results Obtained with Red Cell Agglutination Inhibition and Complement Fixation Tests (Based on Comparative Titrations of Acute and Convalescent Serums)

Test	Virus	Positive	Doubtful	Negative
Red cell agglutination inhibition..	PR8	8	11	6
	Weiss	7	8	9
	L ₂ 47	25	0	0
Complement fixation.....	PR8 600 S	24	1	0
	PR8 30 S	23	2	0

strain, and the complement fixation tests with the two PR8 antigens. The hemagglutination inhibition with the PR8 and Weiss strains either failed to detect any rises in antibodies or it yielded doubtful results, in a number of persons whose convalescent serums showed positive responses by the other two procedures.

The fact that rises were noted with the 600 S antigen of PR8 in complement fixation tests but not in the inhibition of hemagglutination requires further study. It has been shown that there existed a straight line relationship between these two reactions as long as the serums studied were free of antibodies to the 30 S antigen.¹¹ It was noted, furthermore, that on sonic vibration of the 600 S particles, an antigen was released that behaved serologically like the 30 S antigen. It is possible, therefore, that the rises in antibodies demonstrated with the 600 S antigen were actually due to some soluble antigen present in the virus particle. The possible presence of other antigens in the 600 S fractions also remains to be explored.

Single specimens of serum were obtained from a number of other persons. Some were from students who had been vaccinated and had not come down with the disease. These showed high hemagglutination inhibition titers to the PR8, lower levels to the L₂47

virus, and mostly did not contain antibodies to the soluble antigen. Another group consisted of persons who had been vaccinated and who subsequently contracted influenza. Their serums contained antibody to the 30 S fraction of PR8 virus in dilutions of 1:8 or higher. Finally, a number of serums were obtained from students who had not been vaccinated and who escaped the disease. Some of these gave high titers with the soluble antigen, suggesting that these students had undergone a subclinical infection; this implication was further substantiated by a high antibody level to the L₂47 virus in three of four serums reacting with the 30 S fraction.

COMMENT

Two phases of this study require some comment: (1) the diagnostic value of the various available serologic tests, and (2) the failure of the influenza vaccine to protect this group of persons. As to the serologic diagnosis of influenza, the inhibition of hemagglutination has been used for this purpose more or less exclusively in the past several years. This test is relatively simple and effective, as long as the infecting strain of virus is antigenically closely related to the test virus and the antibody level in the acute serum is fairly low. However, it was found^{12, 5} that the new strains in the epidemic of 1943 gave positive results in diagnostic tests in a much larger group of cases than the usually employed laboratory strain (PR8). This relative strain specificity constitutes a distinct drawback to the routine use of the hemagglutination inhibition test. The causative agent of a given epidemic or of sporadic cases may not become available for use as an antigen during the epidemic, or the isolation, if successful, may consume considerable time. It would seem important, then, to use diagnostic tests which are less subject to strain specificity. It has been indicated previously^{12a} that, as opposed to the larger virus antigen, the soluble antigen of influenza virus as present in infected mouse lungs is type specific but not strain specific. This has been confirmed with antigens prepared from the chick embryo.^{12b} The use of virus antigen 600 S and soluble antigen 30 S, prepared from the PR8 strain, for the diagnosis of this epidemic showed clearly the superiority of the complement fixation tests. All serums showed significant responses except two, which showed a doubtful rise in antibodies. This is in striking contrast to the results obtained with the PR8 strain in the hemagglutination inhibition tests. It is recommended that both tests be performed in order to secure reliable and complete information in epidemics and sporadic cases of infections of the upper respiratory tract.

In regard to the value of vaccination of man against epidemic influenza, various recently developed vaccines, which have been tested, proved successful in reducing the incidence of the disease in a number of studies.¹³ Protection was observed by Hirst eight days after vaccination,¹⁴ and Hirst and Salk found it to last, at least to some extent, for more than one year after vaccination;¹⁴ on the other hand, Eaton obtained little if any protection after five to six weeks,¹⁶ a finding more in accord with this year's observations.

One must now consider means of preventing such disappointing results. There are two points which require particular notice: (a) the epidemic occurred three months after vaccination, and (b) the epidemic strain of virus was notably different from the strains in the vaccine. It seems, then, that one must aim at prolongation of the immune response and increased cross protection. Several steps may lead to achievement of these aims: 1. One may strive to obtain higher antibody titers against the strains included in the vaccine because with rises in the homologous antibody levels the cross reacting antibodies usually also increase. This may be accomplished in several ways: (a) by immunization just prior to or in the early days after onset of an epidemic somewhere in this country (under these conditions, the antibodies will be at their height when needed most; this, however, will be a fairly unpredictable method, and one may not always be in time); (b) by the use of more concentrated vaccines, if one can avoid the untoward reactions by some treatment of the vaccine; (c) by the use of certain adjuvants which increase both the antibody levels and their persistence. The technic of Freund,¹⁵ which employs vaccines emulsified in liquid petrolatum, has been applied to prophylaxis in influenza, first by Friedewald¹⁶ in experimental animals and subsequently in man in this laboratory.¹⁷ The results obtained are rather promising, but liquid petrolatum will have to overcome several clinical objections before it will become generally acceptable. However, the data would suggest that an intensive search should be made for other adjuvants which would be equally effective but less objectionable.

A second general approach may be found in the use of different strains of virus for the vaccine; (a) a systematic search for strains of influenza virus with broader specificity seems indicated, and (b) since it appears that major epidemics are often preceded by localized outbreaks, the isolation of strains of influenza virus in preepidemic outbreaks and the inclusion of such strains in the vaccine will be of value if the subsequent epidemic should be caused by a similar strain. The experience with the Weiss strain, which was isolated in May 1943¹⁸ and used in the successful vaccine in the winter of the same year,¹ may be cited as an example. This approach would be a burden to those charged with the preparation of vaccine and it is doubtful whether enough vaccine could be produced in time to institute large scale vaccinations unless certain of the standardization procedures are dispensed with, as was the case with the 1943 vaccines.

It appears, then, that further investigations are necessary in order to increase the efficacy of influenza vaccines.

SUMMARY

An epidemic of influenza A in a school—three months after vaccination of 88 per cent of the students with commercial influenza A and B vaccine—is reported. There was no evidence of protection, although the specific antibody levels in the patients' serums indi-

cated that the vaccine had been of satisfactory potency. However, the epidemic strain of virus differed decidedly from the strains present in the vaccine, which explains the failure of the vaccine to afford protection. The problem of vaccination against influenza is discussed and suggestions for improving the vaccine are made.

ADDENDUM

Since the submission of this paper, a report of a similar situation by Thomas Francis Jr., Jonas E. Salk, and J. J. Quilligan appeared in the *American Journal of Public Health*, 37:1013-1016 (August) 1947.

PROSTATIC SURGERY AND HEART DISEASE

HERMAN L. KRETSCHMER, M.D.

and

STUYVESANT BUTLER, M.D.

Chicago

Patients with prostatic obstruction, either benign or malignant, fall into an age group in which degenerative diseases of the cardiovascular system are of frequent occurrence. In many of these cases the problem of operability is of vital and immediate importance to both the surgeon and the patient.

The presence of cardiovascular disease immediately raises two questions: 1. The urologist is concerned with the nature and extent of the cardiac lesion and the amount and type of the treatment required to make the patient a safe or a reasonably safe operative risk. 2. Many of the patients who have known cardiovascular disease are vitally interested as to whether or not they can be operated on successfully and what amount of risk they assume.

With these questions in mind we have undertaken a study of 314 consecutive patients with a view of determining the incidence, type and severity of cardiovascular lesions and their effect on operability, morbidity and mortality. Multiple resections were carried out to a total of four hundred and four resections. This was done because of unusually large glands, recurring carcinoma and the belief that in some of the cases of bad cardiovascular disease multiple short resections were safer.

We have been interested in this subject for some time. In a previous study by one of us¹ patients with heart disease in all phases of general surgery were studied to determine the effects of various types of heart disease on the surgical risk. At a later date one of us² undertook several studies to determine the incidence of cardiovascular disease in prostatic obstruction and the value of the electrocardiogram in these cases.

Many men in the older age groups have known cardiovascular disease. In many others, however, no symptoms referable to the cardiovascular system had been noted by the patient. In all our cases every attempt was made to make an accurate evaluation of the circulatory system from a study of the history.

From the Departments of Urology and Medicine, Presbyterian Hospital of Chicago.

physical examination and electrocardiogram. Although the electrocardiograms over the years have been read by several different persons, they have all been reappraised by one of us for the sake of uniformity. For the same reason the histories and physical examinations have all been carefully reviewed.

No patient was refused resection irrespective of the size of the gland or because of the cardiac condition, although surgical treatment was often delayed or modified because of the condition of the heart. No suprapubic or perineal prostatectomies were done.

THE INCIDENCE OF CARDIOVASCULAR DISEASE

The study of this series of 314 consecutive cases reveals that there were 112 patients, or 35.66 per cent, who showed evidence of heart disease, either clinically on physical examination or in the electrocardiogram. Many had more than one cardiac lesion (tables 1 and 2). Nineteen patients were in congestive heart failure when admitted to the hospital. With proper

cardiac management they were treated by transurethral resection; they made uneventful recoveries.

There were 45 whose hearts were enlarged more than 2 cm. to the left and 3 patients with demonstrable enlargement to the right. There were 35 patients with hypertensive cardiovascular disease and 2 with cardiovascular renal disease. Eight patients had aortic insufficiency and 8 aortic stenosis. Nine showed mitral stenosis and 39 had mitral insufficiency. Three had aortic stenosis with mitral insufficiency.

HISTORY OF ANGINA

There were 12 patients who gave a definite history of having had previous attacks of angina. Among these was 1 man who stated that he had 1,100 attacks of angina pectoris, for which reason he had been advised elsewhere that he could not be relieved of his prostatic obstruction. This advice was given despite the fact that urinary distress precipitated an anginal attack. His anginal attacks were greatly reduced in both number and severity after two transurethral resections. His postoperative course was uneventful.

There were 9 patients with a history of previous attacks of coronary occlusion with electrocardiographic confirmation in this group.

BLOOD PRESSURE STUDIES

There can be no doubt that abnormally low or high blood pressure adds to the surgical risk. This has been recognized for a long time; hence the importance of

TABLE 3.—*Blood Pressure Records*

careful studies on the blood pressure of the patient with prostatic obstruction. In some of the patients with severe infection and with a large amount of residual urine who have hypertension there is decided reduction in the elevated blood pressure after preliminary treatment with the indwelling catheter or by suprapubic cystostomy. This has been recognized by urologists for many years.

The results of the blood pressure studies are presented in table 3. There can be no question of the fact that the 9 patients whose systolic pressure was below 100 can be classified as having hypotension or that the 47 with systolic pressure over 175 have real hypertension.

There were 22 who had systolic pressures over 200 and diastolic pressures over 100.

THE ELECTROCARDIOGRAM

Should the electrocardiogram be used as a routine procedure in the patient with prostatic obstruction? The answer to this question depends on the following propositions: 1. Does it reveal lesions that cannot be recognized by the history and the physical examination? 2. Does it give any information in addition to that obtained from a careful history and physical examination?

A review of the electrocardiograms disclosed 37 patients with evidence of ancient or healed disease of the coronary arteries; there were 7 with active coronary

occlusion at the time of admission to the hospital. None of the latter were among those with a history of coronary occlusion.

There were 33 cases in which no heart disease had been diagnosed by the history or the physical examination but in which the electrocardiogram revealed evidence of important pathologic changes.

There were 31 patients with disturbances of conduction. These were divided among 4 with bundle branch block, 9 with prolonged interventricular conduction

and 18 with some type of auriculoventricular block, of whom 3 had complete heart block. Twelve cases of auricular fibrillation and 1 of auricular flutter were found; 15 patients had premature ventricular contractions. One instance of dextrocardia was found.

It is interesting to note that of the 31 cases of impaired conduction, 10, including a complete heart block, were not diagnosed except by electrocardiogram.

In view of the fact that in this series of 314 cases there were 112 (35.66 per cent) which showed evidence of heart disease either clinically or in the electrocardiogram, we have considered each case as it presents its individual problem to the surgeon and internist as to whether the cardiovascular disease is a factor. This concerns not only the risk involved in the operation, but also choosing the right time for the operation; that is, whether the resection should be delayed until the circulatory system has been brought to its optimum efficiency. We have considered that in 39 of these cases, while there was evidence of heart disease such

a colostomy it was decided to do a resection, from which he made a complete recovery. On the sixteenth day after resection complete suppression of urine developed. At necropsy both ureters were found completely occluded by metastatic carcinoma.

There were 2 deaths due to aspiration of stomach contents into the lungs, a clinical entity overlooked for many years and recently brought to light by Irons and Apfelmach.

The sixth death was that of a physician. He was an extremely difficult patient who insisted on removing his catheter at will and reinserting it while in bed. This resulted in severe urinary infection with secondary hemorrhage, septic manifestations and terminal pneumonia.

SUMMARY AND CONCLUSIONS

The prognosis as concerns the cardiac patient with prostatic obstruction is good, provided the condition is recognized before operation and proper treatment is instituted. No patient, cardiac or otherwise, has been denied relief of his obstruction. The low mortality and relief of their condition has been made possible for the following reasons: (1) careful preliminary study and treatment of the cardiac condition; (2) the fact that transurethral resection is a less formidable procedure than suprapubic or perineal prostatectomy; (3) the use of modern methods of anesthesia; (4) the use of blood transfusions, and (5) the possibility of getting these patients out of bed the next day after operation when this may be necessary.

ABSTRACT OF DISCUSSION

DR. HAROLD C. HABEIN, Rochester, Minn.: Transurethral prostatic resection can be carried out by the well-trained surgeon with minimal insult to the cardiovascular system. This is borne out by Dr. Kretschmer's report of only one death referable to cardiac failure in his series. There is little question that either suprapubic or perineal prostatectomy in the same group of patients would have been accompanied by a mortality rate of from three to ten times that which Dr. Kretschmer reported. Evidences of marked cardiac decompensation are not hard to recognize; it is the minimal decompensation that is often overlooked. Provided this is recognized, it usually is very easy to establish cardiac compensation. Often drainage of the bladder and rest are all that is required. Electrocardiographic studies are valuable and should be a part of the routine examination of patients in the older age groups. If there is no history of cardiac impairment and no physical signs of decompensation, these patients can be operated on with a high degree of safety. Probably the most important findings derived from electrocardiographic studies are those changes associated with acute myocardial infarction. Operation in the presence of recent coronary thrombosis is extremely hazardous; hence, surgical treatment should be postponed, if at all possible, for six to eight weeks or longer. The most difficult evaluation of surgical risk arises when the patient is suffering from angina pectoris secondary to coronary sclerosis. As Dr. Kretschmer has pointed out, most patients with angina pectoris will undergo transurethral surgery without serious difficulties. But many times, in our experience, patients with severe angina pectoris will withstand transurethral resection without difficulty, whereas those patients who have had only mild angina pectoris will experience the most difficulty. We have had the experience of having coronary thrombosis develop, during or after surgical treatment, among patients who have never had symptoms of angina pectoris. I was surprised at the large number of patients with mitral insufficiency which was reported. In my experience, practically every patient with mitral insufficiency has had a certain degree of mitral stenosis. I believe that every patient with rheumatic endocarditis should have the benefit of preopera-

TABLE 5.—Analysis of Deaths

Name	Age	Diagnosis	Cause of Death	Comment

as hypertrophy or mitral insufficiency, the heart disease was not of such severity as to be an important factor. There remain 73 cases in which the heart or circulation was a real factor in operative risk (table 4).

MORTALITY

There were 6 deaths in this series of 314 patients, or a mortality of 1.9 per cent. On the basis of 404 resections the mortality was 1.4 per cent. The deaths are presented in table 5.

In spite of the fact that there were so many serious cardiac conditions in this series there was only 1 death due to heart disease. This occurred on the tenth day after resection, the day scheduled for the patient's discharge from the hospital, and was due to coronary thrombosis. The second death, from pulmonary embolism, occurred on the fifteenth postoperative day, the day scheduled for the patient's discharge from the hospital. The third death occurred in a patient who one and one-half years before admission to the hospital had had a combined abdominal-perineal resection for extensive carcinoma of the rectum. He entered the hospital with complete retention. He could not tolerate an indwelling catheter. In view of the fact that he had

tive and postoperative chemotherapy or treatment with antibiotics as a prophylactic measure. In the case of the patient with infection of the urinary tract, the organism responsible should be cultured and its sensitivity to penicillin or streptomycin should be used. The appropriate drug should be administered at least three days preoperatively and as long postoperatively as there are evidences of acute infection.

DR. THOMAS A. MORRISSEY, New York: I am certain that Dr. Kretschmer's figures may be fairly closely approximated by numerous other operators and clinics throughout the country. The urologist must make up his mind as to which is more important, the prostatic obstruction or the heart disease. The normal incidents of prostatic obstruction are bound to accentuate a latent cardiac pathologic condition by their associated symptoms—changes in blood pressure and blood nitrogen, frequency, principally nocturia, and interrupted sleep, residual urine with or without infection—so that the relief of the obstruction is indicated as a means rather than an end to the alleviation of the associated cardiac pathologic condition and the increased heart load. Urologists in New York City who do numerous perineal prostatectomies point out the cardiac strain of the operative posture on patients with cardiac impairment. The so-called exaggerated lithotomy position must be considered in the selection of the type of operation. Dr. Kretschmer acknowledges this by his recognition of the need for multiple resections in cases in which a considerable time is occupied with bleeding, etc., in a difficult resection. The anesthesia problem cannot be overemphasized. Low spinal block with exacting attention to level of anesthesia is important in obtaining satisfactory results. However, the anesthetic agents and techniques used are not as important as the judgment, skill and experience of the anesthesiologist. Complications which meant increased heart load are now less of a problem. Sulfonamide drugs, penicillin and ligation of the vas have all been instrumental in elevating the safety of all procedures. Levine has reported a series of over 400 patients with organic heart disease who had been subjected to various types of prostatic surgery. These showed an unexpected mortality of 6.4 per cent. He found that the postoperative complications were the same in the cases involving cardiac disease as in the noncardiac cases. This phase of prostatic surgery cannot be overemphasized. Over ten years ago Dr. Kretschmer emphasized the importance of stabilizing patients with cardiovascular disease who showed electrocardiographic changes with hypertension before operation. The low mortality which he reports in his present series is noteworthy and undoubtedly the result of careful supervision and the application of the principles which he sets forth in the management of these cases.

DR. A. E. GOLDSTEIN, Baltimore: Dr. Kretschmer has called to our attention many of the cardiac conditions that are encountered in the series of cases in which he has operated. All our patients with prostatic disease have some cardiac abnormality. I do not believe that we have ever refused an operative procedure because of a cardiac condition. I am certain that it was not Dr. Kretschmer's intention to convey the idea that the transurethral operative procedure is the only operation that should be performed on patients with cardiac disease. He says that it is a less formidable operation. In my hands it is not so. I, and many other men, can perform perineal prostatectomies in less time with less damage to the patient than the transurethral operation causes. Likewise, I am certain there are many men in this audience who can do a suprapubic operation probably with less damage and less trauma than when they do a transurethral. When he speaks of mortality of 1.9, which is certainly low in comparison with that of a recent report given out by us—252 cases with a mortality of 3.9 per cent—quite true, twice as much—the difference is not of sufficient importance to put into my hands just the transurethral operative procedures for cardiac conditions. We should remember that Dr. Kretschmer is a very able surgeon. He has mastered the transurethral operative procedure, but what about the surgeon in the small country town who is performing transurethral operations, the man who has had little experience? He seems to be able to handle the suprapubic operation much better with

certainly a lower mortality than with the transurethral. In our recent series no one died from a cardiac condition. I would not like this audience to go away from here thinking that the only type of operative procedure to be employed in cardiac conditions is the transurethral. Again I repeat, I am certain that it was not Dr. Kretschmer's thought. Dr. Kretschmer recently visited Baltimore and was at one of our clinics. He saw the perineal operative procedures performed and observed that each patient did not remain on the table over half an hour, which I think is as little time as one can expect to perform any prostatic operative procedure. As to getting patients who have undergone transurethral operations out of bed the first day, we get all our patients on whom the perineal operation has been done out of bed on the first day.

DR. HERMAN L. KRETSCHMER, Chicago: Dr. Habein stressed the importance of obtaining a careful and detailed history in this group of patients. I agree wholeheartedly. In this day of mechanization in medicine, the taking of the history seems to be rapidly becoming a lost art. His point emphasizing just how much work the heart can do on exertion is timely. And, as he stated, it gives one a good idea of just what a heart can do. Dr. Habein called attention to the fact that great care must be used in the administration of fluids. With this I agree. The administration of fluids has become so routine, without consideration of the patient's condition, that cardiac embarrassment has resulted from the routine administration of large amounts of fluids. In answer to Dr. Habein's question on malignant endocarditis, I have had 1 case following transurethral resection. The importance of maintaining blood pressure was mentioned by Dr. Habein. Of course I agree with him in this statement. My experience tallies with his that since the days of resection we too see fewer and fewer cases of pulmonary embolism. Dr. Morrissey's remarks about the increase of heart disease are timely. We are an aging nation. There are more older persons living in this country today than ever before. As a result there has been a definite increase in the number of persons with cardiac disease. In reply to his question about the difference in mortality between suprapubic prostatectomy and resection, may I state that in my experience the mortality and morbidity are much lower with resection. In answer to his question about studies on blood chemistry may I say that they were made and tabulated in our studies but had no bearing on the results and so were not mentioned. Dr. McCarthy called attention to the fact that there are still some differences of opinion on resections versus open prostatectomy. There will always be differences of opinion on surgical procedures, but as time goes on these differences become less and less. I wish to agree with Dr. Goldstein's statement that a man should do the type of operation that he is best qualified to do. The object of the paper was not to make a plea for resection but to present the incidence and extent of heart disease in an unselected series of cases of prostatic obstruction, and to determine the effect of heart disease on mortality.

Myasthenia Gravis.—It seems that by 1927 the clinical concept of myasthenia gravis embodied all important aspects of the present day clinical concept except for the clinically demonstrable effects of certain pharmacologic agents, particularly neostigmine, quinine and curare. The story of this important development begins with the discovery by Harriet Edgeworth of the first effective treatment for myasthenia gravis; that is, ephedrine. Dr. Edgeworth herself was probably the first subject of a therapeutic test for myasthenia gravis. Soon after her announcement of the effectiveness of ephedrine in her case, she submitted to studies at the University of Minnesota. . . . In 1935, Viets and Schwab advocated the use of neostigmine as a therapeutic test for myasthenia gravis. In my opinion, the contention of these authors that the marked strengthening effect of neostigmine in cases of myasthenia gravis is one of the fundamental characteristics of the disease has stood the test of time in spite of occasional protests to the contrary.—Eaton, L. M.: *The Clinical Concept of Myasthenia Gravis, Proceedings of the Staff Meetings of the Mayo Clinic*, Jan. 7, 1948.

TREATMENT OF SLIPPED CAPITAL
FEMORAL EPIPHYSIS

ARMIN KLEIN, M.D.
ROBERT J. JOPLIN, M.D.
and
JOHN A. REIDY, M.D.
Boston

The treatment of epiphysiolysis or slipped capital femoral epiphysis at the Massachusetts General Hospital, since our report in 1943, has been standardized in conformity with our conclusions reported then.¹ Patients with pronounced slipping of the epiphysis have been treated by arthrotomy, reposition of the displaced epiphysis on the neck and fixation by means of a three-flanged nail. Patients with only a minimal slipping of the epiphysis have been treated by lateral nailing in situ, without arthrotomy and without correction of the early deformity.

Any child 9 to 16 years of age, who complains of limp and/or pain in the region of the hip, anterior part of the thigh or the knee is suspected of having a slipped epiphysis. Examination may reveal that he walks with the involved limb in external rotation. On flexion of the hip, this external rotation may be increased or there may be only a slight limitation of internal rotation.

The diagnosis is made from anteroposterior and lateral roentgen views of the hip. The degree of involvement is determined by the distance that the head has slipped from the superior outline of the femoral neck. If this distance (line BC in figures 1 and 2) is 1 cm. or more, the slip is considered pronounced, requiring replacement of the head to its anatomic position. If, however, the slip is less than 1 cm., it is considered minimal and necessitates no alteration of the existing relationship of the femoral head and neck. With all cases of suspected slipping, the lateral roentgen view is the essential and in some cases the only means of determining the amount of slipping present.

Fig. 1.—The upper figures are lateral views, the lower anteroposterior views. Line AB is the superior border of the femoral neck projected. Line BC is the distance from the femoral head to the projection of the superior border of the femoral neck—the distance that the head has slipped.

We are now reporting a survey of 45 patients who had 51 slipped capital femoral epiphyses. Nineteen of these 51 cases were reported previously, in 1943. The

remainder, 32 hips, have been admitted for treatment since January 1943. Of the 19 cases previously reported, only 10 can be analyzed here, for these were the only ones in which treatment was with the three-flanged nail. They have been followed for five to thirteen years. One patient had both hips and four others had single hips nailed in situ, and 4 had an arthrotomy and nailing of the involved hips because the slip amounted to more than 1 cm. Thus, there were

Fig. 2.—Close-up view of abnormal hip (lateral view).

6 cases, or 60 per cent, detected early enough for the hips to be nailed in situ. Four, or 40 per cent, required open reduction before the nailing.

The number of cases admitted annually has been more than doubled since our last report. Obviously, the men in the dispensary are keener to detect a slip of the epiphysis. Nineteen cases were admitted in the five years 1938 through 1942, but there were 32 cases admitted in the last three years. Only 28 patients were treated in this period, however, because 4 had bilateral involvement; i. e., about 15 per cent after admission for a slip of one epiphysis had a slip of the second seven and one-half to twenty-eight months later. This 15 per cent is a drop of 6 per cent from the 21 per cent reported in 1943 for the incidence of contralateral involvement.

Of the 32 cases reported since 1943, in 20 the hips were nailed in situ and in 12 after arthrotomy. Thus, about 62 per cent were recognized early enough for the hips to be nailed in situ, while about 38 per cent required preliminary arthrotomy and reduction. Since these percentages are the same as for the cases reported in 1943, it is evident that though we are detecting more cases of slipped capital femoral epiphyses, we are not seeing them early enough to avoid open operation.

Generally speaking, three types of patients are seen at our clinic: those with a past history of no complaints referable to the hip, but with a definite history of recent trauma suddenly followed by a disabled hip joint; those with a history of gradual onset but with increasing and continuing disability at the hip, and, finally, those with a history of recurrent periods of disability alternating with periods of quiescence and presenting cardinal signs of a slipped epiphysis.

There were only 3 cases in the first group of acute slipping. These patients were treated by manipulation, cautiously slow and extremely gentle. The affected hip was reduced by being brought slowly into flexion with traction, internal rotation and finally extension in

Read before the Section on Orthopedic Surgery at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1947.

abduction. When the reduction was verified by anteroposterior and lateral roentgenograms, the epiphysis was nailed in situ. It should be stressed emphatically, however, that the manipulation must be exceedingly gentle so as to avoid trauma to the surfaces of the joint and consequent traumatic arthritis. If the reduc-

Fig. 3 (J. M.).—Minimal slip of the femoral head on the left, anteroposterior view.

tion cannot be accomplished by only the gentlest manipulation, with the patient under general anesthesia, an arthrotomy for reduction is indicated.

The second group consisted of most of the children whose duration of complaints and whose physical examination indicated the probability of a slow gradual slip, perhaps minimal in amount. These children suspected of having slipped epiphyses were not allowed to stand or walk. They were examined roentgenologically and, on confirmation of the diagnosis, were hospitalized for operation as soon as possible. Such cautious treat-

Fig. 4 (J. M.).—Minimal slip of the femoral head on the left, lateral view. The slip is more apparent in the lateral than in the anteroposterior view. (fig. 3).

ment must be used to avoid further slip, which has occurred in patients treated in the past with plaster spica, splints or even bed rest. These patients with a minimal slip had it nailed under general anesthesia through a lateral incision as for a fracture of the femoral neck.

The third group, those with complaints which were gradual in onset, intermittent and of rather long duration, had pronounced displacement.

After the degree of slip had been determined by roentgen examination, the hip joint was exposed by the Smith-Petersen intrapelvic approach.² The femoral neck was separated from the epiphysis at the epiphysal plate with a curved osteotome or a properly curved hip gouge.

SITE OF OSTEOTOMY FOR REDUCTION OF SLIP

The gouge was kept in place, once the osteotomy was complete, to immobilize the epiphysis and also to serve as a skid on which to manipulate the femoral neck into place. This was accomplished by traction in flexion, internal rotation and, finally, abduction and extension of the femur. As the neck glided down into its corrected position, under visual control of the operator, the gouge was withdrawn from the epiphysal region.

If roentgenograms confirmed correction of the slip in both its anteroposterior and lateral planes, then through

Fig. 5 (J. M.).—Anteroposterior view after nailing in situ.

a separate lateral incision the hip was nailed as for a fracture of the femoral neck.

When the operation was completed, the patient was returned to bed for traction. Buck's extension with a 5 pound (2.3 Kg.) weight was maintained for seven to ten days for the cases of fixation in situ by nailing. In the cases of open reduction balanced traction was used for ten to twelve days or until the sutures were removed. Two weeks after operation, the patients were given crutches and taught to use them correctly. Plaster spicas for postoperative use have been discarded because an analysis of earlier cases in which treatment was given at this hospital by such means has shown a distinct tendency toward stiffened hips. Non-weight-bearing splints had been used for the hips operated on in conjunction with a high sole under the sound lower limb. This method was also discarded because any such brace produced some excessive strain on the hip joint so protected. Finally, the high sole likewise adds strain to the sound hip joint. Patients complained of pain in the sound hip and limped until the high sole was removed. With the possibility of a slip in the

2. Smith-Petersen, M. N.: Arthroplasty of the Hip: New Method. *J. Bone & Joint Surg.* 21: 269-288 (April) 1939.

contralateral hip always in mind, it was logical to give up splints and high soles for crutches alone. A comparative analysis of the records of 6 patients treated with splints and high soles, 5 patients treated with crutches and high soles and 4 patients treated only with crutches showed that there apparently was no harm from the use of crutches alone. The average indexes of motion and of function were fully as good for patients using crutches alone as with any other method, but definitely better than when a splint was used. The use of crutches was therefore advised for the first three months of convalescence.

During this period of convalescence, the child is returned to his normal environment as soon as possible. He may expect to return to school or work after an average postoperative period of thirty-nine days if the epiphysis has been nailed in situ and within three months if the slip has required open reduction.

Patients were examined periodically throughout their convalescence. It was soon obvious that with the clinical type of patient, especially the boys, the admonition to use crutches for three months was not always respected. Nevertheless, it was most gratifying to note the gradual relief of all complaints and the progressive increase in function of the affected hip.

Fig. 6 (J. M.).—Lateral view after nailing in situ.

Both hips, the normal and the one operated on, were examined and appraised as to function. This is the only way to detect any possible slip in the other hip, and by comparison, with the normal hip to note improvement in the one operated on. As in our previous report,¹ function

of the hip was appraised by designating a factor for each motion according to its importance. The amount of demonstrable motion is multiplied by this factor to give a product for that particular motion. The sum of these products represents the "index of motion."³ An example of the use of the index of motion in a specific case follows:

	Motion, Degrees	Factor	Product
Flexion.....	145	0.4	58
Abduction.....	45	0.4	18
Adduction.....	30	0.2	6
Rotation			
Internal.....	30	0.2	6
External.....	60	0.1	6
Extension.....	10	0.1	1
			95

On this basis, the index of hip motion was then computed for the affected hip as compared with the sound hip. Since such an index of motion does not include pain or limp, we assigned equal value to the index of motion, absence of pain and absence of limp, calling

the average of these the percentage of true normal function of the hip.

The results of treatment with nailing in situ of the early slip of less than 1 cm. are analyzed in table 1. There were 31 patients, 4 with bilateral involvement. This entire group of 35 hips was followed for an aver-

Fig. 7 (P. A.).—Pronounced slip of the femoral head on the left, anteroposterior view.

age period of thirty-two months. They showed, on an average, slightly over $\frac{1}{8}$ inch (0.32 cm.) shortening on the nailed side. Their average index of motion was 90 per cent of normal. Only 1 patient had any pain and this was of minor degree, and none had any limp. Their average percentage of normal hip function was 96. Six of this entire group had been reported in 1943 after they had been followed for an average period of fifteen months.

Fig. 8 (P. A.).—Pronounced slip of the femoral head on the left, lateral view.

They have now been reexamined after having been followed for an average period of sixty-five months. At the first report their average index of motion was 82 per cent and their average percentage of normal hip function was 94. Now they show a definite improvement to an average index of motion of 92 per cent and to 96 per cent of normal function (table 2).

3. Ferguson, A. B., and Howorth, M. B.: Slipping of Upper Femoral Epiphysis: Study of Seventy Cases, J. A. M. A. 97: 1867-1872 (Dec. 19) 1931.

Table 3 represents the data on 16 patients with pronounced slipping. They were treated with arthrotomy, osteotomy through the epiphysal plate, replacement of the head to its anatomic position on the neck and lateral nailing of the fragments as described previously. This whole group was followed for an average period

Fig. 9 (P. A.).—Anteroposterior view after osteotomy at the epiphysal line, replacement of the femoral head to its anatomic position on the femoral neck and nailing with a three-flanged nail.

of thirty-three and one-half months. They showed an average shortening of slightly more than $\frac{1}{4}$ inch (0.64 cm.) on the side operated on. Their average index of motion was 85 per cent of normal. Only 1 patient had any pain and this was of minor degree, and only 1 patient limped. Their average percentage of normal hip function was 92.

It is interesting to compare these figures with those reported in 1943 for a comparable group of patients with pronounced slipping and treated likewise by arthrotomy, osteotomy and nailing. In 1943, the average

Fig. 10 (P. A.).—Lateral view after osteotomy at the epiphysal line, replacement of the femoral head to its anatomic position on the femoral neck and nailing with a three-flanged nail.

index of motion attained was approximately two thirds of normal and the average percentage of normal hip function was 76. Now, with greater experience and better convalescent care, there has been an improvement in the average index of motion from 66 to 85 per cent and in the average percentage of normal hip

function from 76 to 92. Four of this group had also been reported in 1943 after they had been followed for an average period of eighty-one months. At the first report their average index of motion was 73 per cent of normal and their average percentage of normal hip function was 79. Now they show a definite improvement from 73 per cent to 90 per cent average index of motion and from 79 to 87 per cent of normal hip function.

In a survey of the roentgenograms of the 51 cases reported,⁴ there were no signs of aseptic necrosis, and only 2 cases showed any signs of traumatic arthritis. These 2 cases were in the arthrotomy group that had an osteotomy through the epiphysal plate and replacement of the epiphysis to its anatomic position. One of these cases by roentgenogram showed signs of traumatic arthritis preceding operation, and the subsequent reaction in the joint was considered an exaggeration of the preceding status. The second case was probably the result of failure to correct the slip completely. In replacing the epiphysis, the reduction must be meticulously complete in both the anteroposterior and lateral planes as shown by roentgenograms taken during the operation and before nailing. Then only will con-

Fig. 11.—Right, hip gouge. Left, gouge following epiphysal line to separate head from neck.

gruous surfaces be in direct apposition throughout the arc of motion in that joint. If the correction of the slip is not complete, any incongruity of the opposing joint surfaces predisposes to traumatic arthritis. Thus, in the 51 cases in which nailing was done, only 2 showed any signs of traumatic arthritis by roentgenogram. One patient thirty-four months and the other eighty-one months after operation had 80 and 58 per cent, respectively, of normal hip function.

CONCLUSIONS

Patients suspected of a slip of the capital femoral epiphysis should immediately be forbidden any weight bearing on the affected limb.

Anteroposterior and especially lateral roentgenograms should be made immediately to confirm the diagnosis and to determine the extent of the slip.

The hip should be nailed as soon as possible, in situ if the slip is minimal, and after arthrotomy and reduction if the slip is pronounced. Nailing in situ is a relatively simple procedure for the surgeon who has been adequately trained. Open reduction and nailing, when required, is a difficult procedure even in the hands of

4. The survey of the roentgenograms of all our cases forms the basis of another report soon to follow in more detail.

the orthopedic surgeon, until he acquires the proficiency gained through experience.

Nailing insures the patient against further slipping of the epiphysis and accelerates fusion of the epiphysal line.

Average	12+	32.4	1/4+	90.49	99.71	100	96.70

Follow-up period: 7 months to 7 years.
Shortening: 0 to 3/4 inches.

Early postoperative mobilization is fostered by Buck's extension for the cases of nailing in situ and balanced traction for the cases of open reduction. Mobilization is further promoted by encouraging walking with the aid of crutches as early as two weeks after operation.

Slip of the contralateral hip should be detected early by periodic examinations continued until the epiphysis has fused.

TABLE 2.—*Lateral Nailing in Situ, Second Report*

(R)	14	5	53	72.3	87.90	100	100	100	100	90.70	95.90
Average	14	16 1/2	65	82.75	92.56	100	98	100	100	94.01	96.92

Manipulation is permissible only in the recent, acute slip.

With hips nailed in situ one can expect 90 per cent normal motion and 96 per cent normal hip function. Those nailed after arthrotomy and replacement will give 85 per cent normal motion and 92 per cent normal hip function. These figures obtain for observation

periods of approximately three years, but are better with longer follow-up.

Traumatic arthritis follows inadequate replacement of the epiphysis.

Aseptic necrosis was not manifest in any case.

Convalescent care of patients with open reduction is practically the same as for those nailed in situ.

The child treated by the nailing method is not kept out of his normal environment for any inordinately long period of time.

To correct a pronounced slip, osteotomy at the epiphysal plate gives a better result than one performed at any other site.

ABSTRACT OF DISCUSSION

DR. H. R. MCCARROLL, St. Louis: After listening to this report, we might imagine that the problem of the slipped femoral epiphysis is completely solved. Unfortunately, I do not believe that is true. Very few of us attempt to measure the degree to which the femoral head has slipped. There is no such thing as a fine line of distinction beyond which we can state that arthrotomy and osteotomy must universally be carried out. In deciding this, we must weigh the clinical picture as well as the roentgen manifestations. I get lost in attempting to study the statistical data of the essayists. If my analysis of their results is correct, all cases would be classified as "excellent," with but 3 exceptions, and these would be 1 good and 2 fair. These figures have not been approached in any other clinic. Since the method of treatment used by the authors has been in general use in this country for several years, it seems strange that their results should be so far superior to most others. The authors have stressed lack of postoperative immobilization and urge early ambulation with crutches. We

have occasionally encountered postoperative absorption of the femoral neck with the femoral head seemingly remaining intact. This manifestation, which must be classed as a form of aseptic necrosis, precludes any possibility of early activity for these patients; yet such a complication is not mentioned in this report. We are advised that hips with minimal slipping should always be nailed to prevent further displacement. I am still not convinced of that fact. With adequate bed rest and skin traction, many of these epiphyses will heal without further displacement and with good results. I should like to rewrite one sentence of the authors' conclusions. Their sentence reads in part as follows: "Open reduction and nailing is a difficult procedure even in the hands of the orthopedic surgeon, until he acquires the proficiency gained through experience." I should change this to read: "Open reduction, osteotomy and nailing is a difficult procedure, even in the hands of the orthopedic surgeon. Period." This operation, although indicated in many instances, is not as simple a procedure as has been depicted for us today. In my estimation, at least, it still carries considerable risk of secondary changes in the hip over which we at present have no control.

DR. TOM OUTLAND, Elizabethtown, Pa.: These results are by far the best reported, and they are so far superior that when I read this paper, I began to look around for the catch in it. If there is one here, it eluded me, even if it has not eluded Dr. McCarroll. I certainly am not rash enough to differ radically with any of the important conclusions that Dr. Klein and his associates have drawn. I do not think that the slight incongruity of the opposing joint surfaces from not quite perfect reduction is very important in the production of traumatic arthritis. The circulation of the femoral head is at best precarious, and anything that interferes with it (and that is probably the factor that results in the slipping of the epiphysis) throws it out more or less completely. If this circulation is not promptly reestablished, some permanent change is bound to occur whether it is coxa magna, so-called traumatic arthritis or frank aseptic necrosis. In other words, since the circulatory disturbance is the fact that causes the slipping, the fate of the femoral head may already be determined before it reaches the hands of the orthopedic surgeon. I have used about the same procedure for the past five years, and have a small series of cases. The only difference in the technic is that I prefer to use skeletal traction rather than even a gentle manipulative reduction. I am not sure that I could exercise the fine restraint that Dr. Klein and his group do by not using force when I am attempting to reduce any bone parts. I have felt that perhaps, rather than a rapid changing of the position of the two fragments by manipulation, the already embarrassed circulation would be less interfered with if it were done gradually by traction. I can only congratulate Dr. Klein on the excellent results he has shown, and hope that my own results in the future may approach that, although I rather doubt it.

DR. FRANK R. OBER, Boston: It is my custom to treat the type of case which Dr. Klein describes with a Thomas splint with a patten and high sole on the other side. These patients have all done exceedingly well, although there may be as much as $\frac{3}{8}$ inch (0.96 cm.) of shortening. If a diagnosis is made early and a single hip is involved, the patients do well. Of course, in a clinic there is a social problem which is a little different. Time may not mean much to children, but it does mean a lot in tying up hospital beds. Nailing slipped heads is not always an easy matter. Although the pin is driven through the neck into the head, the head may push off and rotate. In old cases of slipped femoral epiphysis, the head is dense and as hard as marble. In such cases, it would be wise to reduce the hip and then drill a hole into the head, inserting the pin. A great many of these cases result in loss of motion after the operation.

DR. HAROLD B. BOYD, Memphis, Tenn.: Dr. Klein and his colleagues have given us a good paper. Their results are superior to ours. This is probably due in part to a larger percentage of advanced cases in our series. From the standpoint of prognosis and treatment, we have divided our cases into four groups. First, complete traumatic separation of the epiphysis. These patients usually have a slipping epiphysis which is com-

pletely separated by superimposed trauma. In our experience, these completely separated epiphyses, due to acute trauma, usually undergo aseptic necrosis despite accurate surgical reduction and maintenance of the position by internal fixation. I should like to ask whether patients of this type have been included in the series reported by the authors. The second group consists of gradually slipping epiphyses in which the displacement is less than one third of the diameter of the neck of the femur. Usually the displacement of the epiphysis is less than 1 cm. These we prefer to treat by the insertion of three Knowles pins, using roentgenographic control. The hip joint is not opened. In this group, good results have been obtained and no incidence of aseptic necrosis has been seen. In group 3, the epiphysis has slipped more than one third of the diameter of the neck. In most of these patients, we have performed a cuneiform osteotomy through the neck of the femur. After removal of the wedge of bone and correction of the deformity, Knowles pins are used for internal fixation. In this group, approximately 50 per cent have had good hips; the other 50 per cent range from fair to poor and in 2 patients almost complete ankylosis resulted. We have noted aseptic necrosis of the epiphysis in a few cases in this group. In group 4 the epiphysis is united in malposition. After severe slipping of the epiphysis, there is usually an associated external rotation of the hip. In old cases of neglected bilateral slipping, the patient may walk with the thighs externally rotated 80 to 90 degrees, with a gait resembling that of Charlie Chaplin. These patients are difficult to treat. Often the best solution is a trochanteric osteotomy to correct the external rotation. In these severely deformed neglected patients, the prognosis is poor regardless of the type of treatment.

DR. CARL BADGLEY, Ann Arbor, Mich.: I have no reason to doubt the excellent results which Dr. Klein and his group have shown. I believe that they have had these excellent results. I believe that the method of treatment which they have advocated is an excellent one. I think that we are arguing about the end results in different types or stages of this lesion. I have no doubt that if we get the early case and employ internal fixation, we have done the best we can do to prevent the catastrophe of a slipped epiphysis. There is no reason why I should deny the honesty of the authors. Our results, on an average, of all of our cases are 65 per cent good functional hips. Far better statistics could be given in early cases. That includes the entire group. Some patients with bad displacements have the epiphyseal line fused. One should not attempt, in our experience, to replace the head when the epiphyseal line is fused. That is an indication for a subtrochanteric osteotomy. We also have found that a screw or the Knowles pin is much easier to employ than the nail. I do not think that it makes much difference, as long as one uses internal fixation. I wish to compliment the authors on an excellent paper.

DR. JOSEPH S. BARR, Boston: As Dr. Badgley has come to the defense of the veracity of the statistics, perhaps I do not need to say anything. Some years ago, in looking up our end results on slipped epiphyses, we were appalled by the number of poor results. The staff wished to reassess our methods of treatment, and to go along some new lines of thought. This was then made a special assignment, and placed in the hands of Dr. Klein, Dr. Joplin and Dr. Reidy. It has been a long time job. Dr. Klein and his associates have been in sole charge of this work. Each year their results are reassessed before our staff, with a frank and open discussion. Before this paper was read here, it was read before our complete staff, and it was freely and thoroughly criticized. I can assure you that these patients were seen. They were not evaluated by questionnaire. I do not know the exact numbers that were lost, but it was a very small percentage. I wish to emphasize that the open reduction and replacement is technically an extremely difficult procedure, and many of our staff freely admit that we are not nearly as well qualified to do them as the men who have the special assignment. As to the question of aseptic necrosis, there has been none recognized in this series of cases. I have seen the roentgenograms in these cases. They are available to Dr. McCarroll or any of you who wish to study them. If you pay the postage, we will send the

roentgenograms, and you can look at them yourselves. It is a small series, and when it gets to be 100 or over, we may find—and I think that probably we will find—that there will be a small percentage of aseptic necrosis. I do not believe that it will be as large as in previously reported series, in which forceful manipulations have been done and patients have been kept in plaster for long periods.

DR. H. WINNETT ORR, Lincoln, Neb.: Since Philip Wilson's paper about ten years ago on the open fixation of the head, we have done a certain number by that method. I want to emphasize that no surgeon should attempt to nail a head in this kind of a hip until he has reduced the displacement. Some of the roentgenograms shown here this morning prompt me to make that remark. If you do know how to reduce the displacement, primarily, if you know how to hold it during the operation and know how to hold it postoperatively, in about 75 per cent of the cases, no operation is necessary.

DR. JOHN A. REIDY, Boston: The osteotomy of Dr. Badgley is something that definitely should not be done unless the epiphysis is actually fixed to the head, so that there is no question of further slipping. If you can do an osteotomy and use internal fixation which will allow early motion of the hips, the results might be satisfactory. The important thing so far as our treatment is concerned is the early mobilization of these hips. The circulation may be greatly impaired by the operative procedure, but early function can help reestablish a relatively normal physiology with a satisfactory return of circulation and prevention of aseptic necrosis. Dr. Boyd's cuneiform osteotomy, in our experience, has been unsatisfactory. It is a more difficult procedure and one in which more bleeding is apt to result. I think that it interferes with the circulation to a greater degree than does the osteotomy through the epiphyseal plate. Closure of the epiphysis might be hastened by using two pins rather than the three-flanged nail. We have seen several cases in which the nailing has been complete, yet growth continued to take place from the epiphysis. In 1 or 2 cases the head grew away from the nail. These cases must be watched for further slipping as long as the epiphyseal plate remains open. Dr. Outland's roentgenograms suggest that what he has done is satisfactory, and if the slip can be reduced by this type of traction, done gently, good results should be obtained. The statistics on these cases were difficult to obtain, and we disliked using such complicated figures, but, using a modification of the method first applied by Ferguson and Howorth, we felt it was the simplest way to arrive at an accurate evaluation of the joint function. In examination of the hip a deep knee bend might indicate a very good result; yet internal rotation and abduction could be lacking. If all motions of the hip are examined and specific values given each, according to its importance, a fairly good estimation of the function can be obtained. These cases were evaluated by the three of us in this way in most instances, and in some by the whole orthopedic staff.

Occupational Therapy Needs Research.—Occupational therapy received its first trial in modern times when, toward the end of the eighteenth century, William Cullen advocated farming for mental patients and by its results directly influenced Pinel to accept and introduce occupational treatment for mental disease. Physicians in many countries soon accepted this apparently successful method, and the use of occupational therapy gradually increased until it reached a peak toward the middle of the last century, after which it steadily declined until the beginning of this century for reasons which are not too clear. . . . The intensification of occupational therapy during the second World War accounted for more than a twofold increase in its use and should lead thoughtful persons to the question, "Is occupational therapy a war therapy? Was it overpublicized to the lay public and underproven to the medical profession?" Already we can read reactions to its greatly accelerated use which are disconcerting but must be answered. . . . Here then is the first challenge—we are on trial again. To this challenge there is and can be only one answer—research.—Licht, Sidney, M.D., *Modern Trends in Occupational Therapy, Occupational Therapy and Rehabilitation*, December, 1947.

CHEMOTHERAPY OF LEPROSY

G. H. FAGET, M.D.†
Medical Director, United States Public Health Service
and
PAUL T. ERICKSON, M.D.
Senior Surgeon, United States Public Health Service
Corville, La.

Early in 1941 a new drug, "promin," was introduced in the treatment of leprosy at the National Leprosarium. After several months' treatment of a few patients with this drug rather decided improvement occurred in their specific leprosy lesions. In November 1943 the "promin" treatment of leprosy was first reported in the medical literature¹ and was regarded as the most encouraging experimental treatment ever undertaken at the National Leprosarium. Since then "promin" and its related sulfones, "diasone" and "promizole," have been used extensively in the treatment of leprosy with exceedingly good results.

At the Second Pan-American Leprosy Conference held in Rio de Janeiro, Brazil, in October 1946, the Subcommittee on Therapeutics took cognizance of the divergent opinions on the effect of chaulmoogra oil and its derivatives in the treatment of leprosy.² The committee advised that the efficacy of chaulmoogra oil be reevaluated. Simultaneously, it recognized the sulfone drugs as having an efficient therapeutic action in lepromatous leprosy, but felt that it was too early as yet to approve them as definite chemotherapeutic agents for this disease.

We are in a transitional period as far as the treatment of leprosy is concerned. It seems that chaulmoogra oil will gradually be abandoned as an inadequate remedy³ and that the sulfone drugs will replace chaulmoogra oil until a better treatment is evolved. It is the purpose of this paper to acquaint the members of the medical profession of this country with this new treatment and, at the same time, bring up to date our experience with the sulfone drugs and the antibiotics in leprosy.

THE SULFONE DRUGS

"Promin" is the sodium salt of p,p'-diaminodiphenyl-sulfone-N,N'-didextrose sulfonate. "Diasone" is disodium formaldehyde sulfoxylate diaminodiphenylsulfone. "Promizole" is 4,2'-diaminophenyl-5'-thiazolylsulfone. Diaminodiphenylsulfone, the parent chemical from which these drugs are derived, seems to be the active principle of each.

It is well known that the sulfone drugs were first assayed with satisfactory results in experimental animal tuberculosis by Feldman and associates,⁴ Calloman⁵ and others. They were later put to therapeutic

test in human tuberculosis by Hinshaw,⁶ Petter and Prenzla⁷ and others, with conflicting findings. At present it seems that the sulfone drugs have been abandoned in clinical tuberculosis in favor of antibiotics. Whether this is a wise decision only time will tell.

TECHNIC OF ADMINISTRATION

In leprosy, oral administration of "promin" was tried first but proved to be too toxic. The patients could not tolerate an adequate dose. Since then intravenous injections of "promin" have been favored in all cases.⁸

The dose of "promin" which consistently gives good results with a minimum of toxic effects is 5 Gm. daily. An initial dose of 1 Gm. daily being increased gradually, this dose is attained in the majority of patients. The most frequent toxic manifestation encountered is a slow destruction of erythrocytes. Infrequently, leukopenia and allergic dermatitis occur. Nausea, vomiting or headaches are seldom encountered and are never severe. Sneezing occurs rather frequently immediately after intravenous injection of the drug but disappears in a few minutes. Hematuria has not been seen in our group of patients but may develop on high dosages. In some patients who experience repeated toxic reactions the maximum dose may not exceed 2 Gm. Experience has shown the wisdom of discontinuing treatment for one week after each two weeks of daily intravenous injections of "promin." This routine technic has resulted in fewer and milder types of toxic reactions. During the week of rest, sufficient time is usually afforded the patient's hemopoietic system to restore the blood cells lost through the hemolytic action of this drug. It is seldom necessary to administer iron and liver extract as adjuvants for anemia. Urinalysis and red and white blood cell counts and hemoglobin estimations are performed for each patient every three weeks to detect early manifestations of toxicity.

The blood concentration of "promin" following each intravenous administration rises rapidly but is transitory. The drug is rapidly eliminated in the urine, and usually only a trace or none remains in the blood stream at the end of twenty-four hours. The rapid elimination of "promin" from the body together with its relatively low toxicity on present recommended dosage has suggested the use of a larger daily dose given in several divided doses or over a period of several hours as with the multiple syringe or intravenous drip methods. Occasionally, however, in patients with renal impairment, after a prolonged course of treatment there is apt to be an accumulation of "promin" in the blood. In such cases, high blood levels, reaching 20 to 30 mg. per hundred cubic centimeters in twenty-four hours, have been found and the dosage must be materially reduced.

"Diasone" therapy was initiated in July 1943.⁹ Muir's experience with "diasone"¹⁰ has been somewhat

similar to ours but was of a shorter duration. "Diasone" has the advantage over "promin" of being less toxic by oral administration; otherwise, its toxic effects are similar to those of "promin." Treatment should be started with small doses, which are gradually increased as the patient builds up a tolerance for the drug. At present, treatment is started with one 0.3 Gm. capsule or tablet by mouth daily. Provided no toxic reactions are observed in two weeks, the dose is increased to two 0.3 Gm. capsules or tablets a day. After a few more weeks, in the majority of patients, the optimal dose of 0.3 Gm. three times a day is tolerated. Rest periods of two weeks are advisable every two months. Periodic laboratory examinations of blood and urine are necessary, as with patients taking "promin." Occasionally it is found necessary to administer iron and liver extract to counteract secondary anemia.

Blood levels of "diasone" have been found to be low, since the drug is rapidly excreted in the urine. An initial rise of several milligrams per hundred cubic centimeters declines to from 1 mg. per hundred cubic centimeters to a trace twelve hours after the evening dose.

"Promizole" as a treatment of leprosy was started in March 1945.¹¹ It is administered by mouth in tablets or capsules containing 0.5 Gm. each. At first 0.5 to 1 Gm. is given three times a day. After one to two weeks this dose is gradually increased to individual tolerance. An optimal dose of 6 to 8 Gm. a day is seldom exceeded. Toxic manifestations are rare and usually mild but, when they occur, are similar to those of "promin" and "diasone" therapy.¹² Frequent clinical and laboratory examinations are likewise necessary to detect any untoward manifestations early.

With large daily doses of "promizole" it is found that the blood level declines rapidly and reaches 1 to 2 mg. per hundred cubic centimeters twelve hours after the last dose.

None of the sulfone drugs produce crystalluria. No evidence of renal damage has been observed under the carefully controlled technic of medication employed in this institution. Early in our experimental study with "diasone," when a large initial dose of 1 Gm. daily was used, a few cases of hematuria were encountered. Even in these patients no crystals were recovered from the urine after careful search, and the causative factor of the hematuria was not determined.

THERAPEUTIC EFFECTS

With but few exceptions, only patients with lepromatous leprosy, and mostly with far advanced disease, have been subjected to sulfone therapy. While no claim is made that these drugs are specific remedies, they have proved therapeutically more effective in leprosy than any previous treatment tried at the Carville Leprosarium. Unfortunately they work slowly. Definite objective improvement, as a rule, seldom becomes manifested before six months of treatment. Thereafter, improvement is progressive with few, if any, relapses. The disease seldom, if ever, appears to get worse under treatment. The percentage of patients improved is in direct proportion to the dura-

tion and the intensity of treatment. It is our impression that the progress of improvement is similar with each of the three drugs. The diaminodiphenyl sulfone parent radical, common to all, appears to be the active principle. That the patients in the "promin" group are

Fig. 1 (case 1).—Before treatment.

as a whole in the best condition at present can probably be attributed entirely to their being under treatment for the longest period of time.

Experience has shown that the relation of improvement to duration of treatment can be approximately

Fig. 2 (case 1).—After treatment for two years with "promin."

estimated. After six months of treatment almost 25 per cent of the patients show some improvement. After one year this percentage is increased to 60, after two years to 75, after three years to almost 100. The extent and stage of the disease does not suppress the

action of the sulfone. Even far advanced lepromatous disease is checked and improves under treatment. The extent of improvement usually varies proportionately with the size of the dosage tolerated by the individual patient. The use of a larger daily dose of "promin" than that at present recommended, given by the multiple syringe or intravenous drip methods, has not been sufficiently explored as yet to determine whether or not improvement might be hastened without danger.

Only objective improvement has been considered in evaluating the therapeutic action of the sulfones. Clinical objective improvement is substantiated by photographic and laboratory evidence.

Clinical improvement in cases of lepromatous leprosy is manifested in various ways. Small nodular lesions slowly shrink and flatten to complete absorption. Finally only a pigmented spot usually remains. Larger and deeper nodular lesions disintegrate more slowly with subsequent scar formation. Infiltrative plaques gradually subside with diminution of inflammatory swelling and edema of dermal tissues. Leprous ulcerations of extremities gradually form healthy granulations and heal through cicatrix formation. Trophic plantar ulcers become disinfected, granulate and gradually close with residual callosities. Occasionally regrowth of hair may follow resolution of lepromatous lesions. This has been found to occur in eyebrows, beard and arms and legs.

Mucosal lesions appear to respond more rapidly than cutaneous lesions. Oral nodules and infiltrations usually subside and disappear after a few months.

Oral ulcerations also heal within a few months to a year. Nasal obstruction is relieved through subsidence of the inflammatory mucosal lesions of leprosy rhinitis. Epistaxis is checked by the healing of nasal mucosal ulcerations. Improvement in leprosy laryngitis occurs frequently, with restoration of the patient's voice and relief of dyspnea. Emergency tracheotomies generally become unnecessary.

Sulfone therapy appears capable of checking the progress of conjunctival, corneal and iridocyclitic leprosy infiltration. There is occasional improvement of impaired vision.

ACUTE LEPRO REACTIONS

Attacks of acute lepro reactions with erythema nodosum or erysipeloid dermatitis are not commonly aborted by sulfone therapy. Patients experiencing such episodes previously may have recurrences during the course of treatment. However, the frequency as well as the severity of subsequent attacks is lessened by this treatment. In only a few cases, severe attacks have occurred despite treatment. In some of these instances it was found best temporarily to discontinue the administration of the sulfone drugs.

Fig. 3 (case 2).—Before treatment.

Attacks of acute iridocyclitis may occasionally occur during the course of sulfone therapy. These are generally mild and subside on continuation or intensification of treatment. Episodes of acute leprous neuritis are also not prevented or aborted by sulfone therapy. However, it is believed that these drugs are not

responsible for the initiation of these acute inflammatory reactions in leprous nerves.

BACTERIOSCOPY

Another feature in the improvement during sulfone therapy is the reversion of skin and nasal smears from bacteriologically positive to negative. Statistically, it has been found that the percentage of bacterioscopically negative smears among treated patients is in direct proportion to the duration of

Fig. 4 (case 2).—After eighteen months of treatment with "diasone."

treatment. During the first year of treatment, practically all cases of lepromatous leprosy remain bacilliferous. During subsequent years of treatment, an ever increasing proportion of patients revert from positive to negative in the routine monthly skin and nasal smears. After four years of continuous intensive treatment the incidence of negative reports exceeds 50 per cent. This strongly suggests that the sulfone drugs have some bacteriostatic properties against Hansen's bacillus.

A study of the histology of lesions before and after prolonged treatment with "promin" has been reported

by Fite.¹³ His findings indicate that "promin" appears to eliminate bacillary infection from the blood stream and the small blood vessels, thereby preventing the formation of new lesions. Improvement under "promin" does not seem to be accompanied by characteristic cellular changes. The histologic changes which do occur are predominantly of an atrophic nature,

Fig. 5 (case 3).—Before treatment.

with gradual lessening of the number of acid-fast organisms present in the lesion to the point of final disappearance.

Three brief clinical abstracts together with photographs before and after treatment will serve to demon-

strate further the therapeutic effects of the diamino-diphenyl sulfone preparations "promin," "diasone" and "promizole" in leprosy.

REPORTS OF CASES

CASE 1.—A Mexican woman, aged 23, had far advanced lepromatous leprosy at the beginning of treatment with "promin" in October 1944. The disease was of about five years' standing. Clinical manifestations at time of admission in April 1942 were: extensive confluent lepromas covering almost the entire face, body and limbs; a few small ulcers on right elbow. The disease progressed unfavorably with chaulmoogra oil given orally and intramuscularly over a period of two and one-half years. Skin and nasal smears were always positive for *Mycobacterium leprae*. After twenty-four months on "promin" therapy, 5 Gm. intravenously daily, the patient was discharged with the disease arrested. At the time of discharge there were no active lesions present and the patient had been bacterioscopically negative for twelve consecutive months (figs. 1 and 2).

CASE 2.—A Negro man, aged 32, had moderately advanced lepromatous leprosy of about six years' duration. Clinical manifestations were: multiple nodules, discrete and confluent, scattered over forehead, ears, cheeks and nose; a few small nodules scattered over both arms and legs. No improvement was noted with chaulmoogra oil given orally and intramuscularly over a period of two years. Skin and nasal smears were always positive for *M. leprae*. The patient was discharged with disease arrested after nineteen months of treatment with "diasone." The dosage was 1 Gm. daily. At the time of discharge there were no active lesions present and the patient had been bacterioscopically negative for twelve consecutive months (figs. 3 and 4).

Fig. 6 (case 3).—After twelve months of treatment with "promizole."

CASE 3.—A Mexican man, aged 35 years, had fairly early active mixed type of leprosy at the beginning of treatment with "promizole." The disease was of about six years' standing. Prior to April 1945, when "promizole" was begun, he had received only eleven intramuscular injections of chaulmoogra oil in 1941 and sixteen in 1942 and chaulmoogra oil by mouth in doses of 25 minims (1.5 cc.) three times per day regularly from 1942 to 1945. When "promizole" was begun the clinical findings were as follows: discrete eruption of brown nodules over the face, ears, limbs and body, becoming confluent in some areas over the face and ears, and some areas of anesthesia over feet, ankles and lower third of legs. Nasal and skin smears were positive for *M. leprae*.

"Promizole" has now been administered in doses of 6 Gm. daily for a period of twenty-three months. Definite improvement has taken place in the shrinking of all nodules after one year of therapy. At present skin and nasal smears are negative (figs. 5 and 6).

STATISTICS

Up to the present at the Carville Leprosarium sulfone therapy of 371 patients has been initiated. The accompanying table reveals the extent to which "promin" and "diasone" have been used and shows the number and percentage of arrested cases obtained in patients treated with these drugs in relation to duration of treatment.

¹³ Fite, G. L., and Gemar, F.: Regressive Changes in Leprosy Under Promin Therapy, *South. M. J.* 39: 277, 1946.

The "promin"-treated group has been excluded, since only 20 patients have been treated for a period too short for proper evaluation. Another group of 36 patients, treatment of whom was initiated but later discontinued, has also been deleted. The reasons for discontinuation of treatment were as follows: (1) voluntary absence, 14; (2) deaths mainly from inter-current disease or accidents, 13; (3) toxic manifestations or inability to take drug, 7, and (4) aliens deported from this country, 2. A small group of patients has received at least six months' treatment with either "promin" or "diasone" before changing from one to the other because of inability due to toxic manifestations or other reasons to take one drug and not the other. Four patients of this group are at present receiving "promin" and 14 "diasone."

The "promin" and "diasone" groups comprise 317 patients who have been treated for varying periods up to six years. Eight have been under treatment for five to six years, 37 for four to five years, 44 for three to four years, 76 for two to three years, 60 for one to two years and 92 for less than one year. In the "promin"-treated group there are 178 patients; in the

arrested disease, although 1 who has had about four years of treatment will soon meet the necessary requirements. These patients because of intolerance to the drugs or for other reasons were rather irregular in taking treatment.

In the entire group there are 38 patients discharged with arrested disease, representing 11.9 per cent of all the patients treated with "promin" or "diasone." That the percentage of patients discharged with arrested disease for the entire period is greater in the "promin" (17.4) than in the "diasone" group (5.8) can, perhaps, best be explained by the fact that the patients treated with "promin" have been under treatment for a longer time. Any attempt to compare the efficacy of these drugs in arresting the disease must await more prolonged treatment with "diasone."

During the year 1946 the number of patients discharged with arrested disease has more than doubled the annual average for the ten years prior to the institution of sulfone therapy, and the number of deaths was less than half the annual average for the previous years. Since the hospital population has not varied significantly in number or composition during the peri-

Number of Cases of Leprosy Treated and the Number and Percentage of Arrested Cases Secured with "Promin" and "Diasone" Therapy in Relation to Duration of Treatment

* An arrested case is one having twelve consecutive months of negative bacterioscopy including skin and nasal scrapings and being free from any other signs of disease activity for at least one year.

"diasone"-treated group 121 and in the group that received both drugs at one time or other, 18.

Thirty-one, or 17.4 per cent, of the "promin"-treated patients have been discharged with arrested disease. An arrested case of leprosy in this institution is defined as one having twelve consecutive months of negative bacterioscopy including skin and nasal scrapings and being free from any other signs of disease activity for a period of one year. Of the 31 discharged patients 3 were under treatment from one and one-half to two years, 7 from two to three years, 11 from three to four years, 8 from four to five years and 2 over five years. There have been no known relapses, and 11 of these patients have chosen to remain under observation in the institution. The period of observation following arrest of the disease has varied from a few months to three years.

Seven, or 5.8 per cent, of the patients treated with "diasone" have been discharged with arrested disease. Of these 1 had the tuberculoid type of leprosy; he was treated for less than a year, and the disease would undoubtedly have become arrested without treatment. Two of the other 5 were treated from one to two years, 2 from two to three years and 2 from three to four years. Four of these have since remained under close observation for four months to two years without recurrence of the disease.

The group of patients having received "promin" and "diasone" at different intervals present no cases of

ods under consideration, this good record can be attributed entirely to the beneficial effects of sulfone therapy.

The ultimate value, however, of sulfone therapy in leprosy is not definitely established. This must await the test of time, five to ten years and possibly even longer. Only then can one be reasonably sure that relapses will not occur.

ANTIBIOTICS

Among the antibiotics penicillin has been used and streptomycin is at present being investigated in the treatment of leprosy. As reported by one of us¹⁴ and by Mom,¹⁵ penicillin, except for some favorable action on secondary infections of leprosy ulcerations, does not influence the course of the disease.

Treatment with streptomycin has been investigated in a group of 10 patients with lepromatous leprosy for a period of eight months.¹⁶ The drug was administered intramuscularly in doses of 0.25 Gm. (250,000 units) every three hours for a total of 2 Gm. (2,000,000 units) in twenty-four hours. This treatment was continued without interruption, except in 2 cases, for four months. Thereafter, because of rather severe

15. Mom, A. M., and Sister Maria Bernal: Penicillin in Treatment of Leprosy, *Internat. J. Leprosy* 14: 37, 1946.

16. Faget, G. H., and Erickson, P. T.: Use of Streptomycin in the Treatment of Leprosy: A Preliminary Report, *Internat. J. Leprosy*, to be published.

toxic manifestations in the form of vertigo, tinnitus, loss of hearing, fever, cutaneous eruptions and an intense eosinophilia, the dosage was reduced to 0.5 Gm. every twelve hours for a total of 1 Gm. (1,000,000 units) in twenty-four hours.

Therapeutically, encouraging changes seemed to occur in the leprosy lesions in some cases during the first three months of treatment. There appeared to be some changes on the improvement side in some of the nodular and macular lesions. Nasal obstruction and epistaxis were relieved in a few cases. A leprosy ulcer of the soft palate healed rather rapidly in 1 patient. After this initial response, further improvement was not tenable, suggesting development of resistance to streptomycin by *M. leprae*.

Although encouraging therapeutic effects from streptomycin seemed to occur, they are not as yet conclusively demonstrated. Also, when the drug is given in large and continuous dosage over a prolonged period of time it produces toxic manifestations which seem to be too severe in comparison with the results obtained. For comparable results the sulfones have thus far been found to be less toxic and therefore more feasible in the treatment of leprosy.

CONCLUSIONS

In the chemotherapy of leprosy with the sulfone drugs "promin," "diasone" and "promizole," objective clinical improvements are produced which are sustained and cannot be attributed to spontaneous remissions in the disease. These objective improvements, although slow in their development, are progressive during the course of treatment. They are substantiated by the photographic changes which occur in the lesions. Laboratory examinations indicate that the sulfone drugs have a bacteriostatic action in leprosy.

Since the sulfone drugs are slowly acting chemotherapeutic agents, further research should be continued in the hope of discovering more powerful bactericidal agents.

Streptomycin is an antibiotic deserving further investigation as a possible chemotherapeutic agent for leprosy. Toxic effects, however, seem to be too severe in comparison with results obtained.

Until faster acting remedies are discovered, the sulfone drugs must be considered the optimal treatment of leprosy. Their further investigation in all leprosy throughout the world is recommended.

ABSTRACT OF DISCUSSION

DR. HAROLD M. JOHNSON, Honolulu, Hawaii: At last we are on the threshold of optimism and may later even cautiously mention the word "cure." The encouraging reports of Faget and his group influenced Dr. Norman R. Sloan of Kalaupapa settlement, on the island of Molokai, to seek these promising drugs. "Promin" and "diasone" could not be obtained until May 1946. Chaulmoogra oil and its derivatives had long been discarded in Hawaii. Diphtheria toxoid and quinacrine hydrochloride had their trial without success. "Promin" has been given to 106 patients at Kalaupapa at about the same dosage and routine as used at Carville. Seventy-two have received "promin" for six months or more. A conservative estimate shows that 55 are definitely improved, 8 stationary or doubtful and 9 worse. This last group is composed principally of patients suffering from intercurrent lepra reactions. One hundred and

nine patients are now receiving "diasone," but it is too early to evaluate as the drug has been used only a few months. It appears to be as effective as "promin" and its oral use renders the drug easy to administer. The Pyridium Corporation's drug 806 (2-butoxy-5-aminopyridine sodium formaldehyde bisulfite) is being used on 8 young patients. In 1 a severe hematuria developed after seven weeks and the drug was stopped. Dr. Sloan believes that it has produced a definite regression of facial lepromas in several cases. The toxicity may restrict its use. At the Kalihi receiving hospital, near Honolulu, 21 patients are being treated with "promin." In these cases the disease is not so severe and active as in Kalaupapa, but Dr. Edwin Chung-Hoon has enough material correctly to evaluate the improvement. The results and reactions closely parallel the cases treated at Kalaupapa. "Diasone" is also being used when intravenous injections are impossible or undesirable. "Diasone" is not an innocuous drug. It has caused more reactions than "promin." One patient at the Kalihi hospital died with agranulocytic angina. "Diasone" was the etiologic agent. It is not unusual to see a Herxheimer-like reaction in the tuberculoid and lepromatous types. This can be alarming if laryngeal lepromas suddenly swell and produce stenosis. A few cutaneous reactions have occurred but nothing more than urticaria and fleeting macular exanthems. Fatigue, cyanosis and anemia must be watched. The cases of tuberculoid leprosy responded well undoubtedly because of less virulent phase of this type of leprosy. It is well known that the cases of tuberculoid leprosy undergo regression without treatment, but the reactions subside much faster with "promin" and "diasone."

DR. M. T. VAN STUDDIFORD, New Orleans: Those suffering from Hansen's disease have a psychology all their own. Any agent which causes a rise of temperature or is followed closely by acute lepra reactions is quickly avoided by them. The older inmates of the hospital have become good prognosticators and have discarded chaulmoogra oil for the sulfones. These they take with enthusiasm, preferring in the main "promin." In this report the authors have dealt with the sulfones separately and have shown statistical results superior to any previous methods or drugs. Using six, twelve, eighteen and twenty-four month periods of treatment, they have shown a gradual improvement in the lepromatous group; they have shown that there has not yet been a cure-all found but that results are so promising that with improvements in methods in maintaining longer, higher blood concentrations and with improvement of the drugs, a higher percentage of cures can be expected in the future. Hansen's disease is not to be reckoned in months but in years or decades. We are not dealing with a hurry-up job. Reactions of the skin to the sulfones are commonly a rosacea-like eruption on the face, shoulders and arms. The discrete lesions resemble papular necrotic tuberculids. These involute slowly if treatment is stopped but seldom cause enough reaction to discontinue treatment. One must keep certain facts in mind in the treatment of Hansen's disease; namely, that tissue which has been affected is slowly, if ever, replaced; changes for good or bad come and go; several years of improvement might be lost in weeks or months, but with any treatment that has accomplished continuous good results, as have the sulfones, a brighter outlook can be maintained until a better treatment is found.

DR. PAUL T. ERICKSON, Carville, La.: It is somewhat disheartening to hear that a death has occurred from the use of "diasone" in the treatment of leprosy. Since this death was apparently due to agranulocytosis, it emphasizes the need for close observation on white blood cell counts and differential counts in patients under treatment with this drug. We have not had a single death from drug toxicity from any of the sulfone drugs and toxic manifestations have been rather mild. Some patients have been taking "promin" daily for as long as six years and "diasone" daily for three and one-half years, except for rest periods, and have done very well. A constant vigil, of course, has been maintained to discover signs of toxicity early. Patients with decreased renal function have been

kept on lower dosages. I did not mention much about the subjective improvement or the gain in weight which is so noticeable in our patients after sulfone therapy. The great majority say they have more pep, sleep better and feel much better. Gain in weight is general; some patients have to be cautioned about gaining too much weight. Finally, a word of caution is necessary. I do not wish to leave you with an impression that is too optimistic. Arrested cases of leprosy were secured on chaulmoogra oil when that drug was so much used. After three to five years, however, many of these persons with so-called arrested leprosy returned in a condition much worse than at their original admission. I hope the same will not occur with cases arrested on the sulfone drugs; only time will tell.

ETHICS GOVERNING THE SERVICE OF PRISONERS AS SUBJECTS IN MEDICAL EXPERIMENTS

Report of a Committee Appointed by Governor
Dwight H. Green of Illinois

INTRODUCTION

During the war the Governor of the state of Illinois and the Department of Public Safety permitted prisoners in one of the state penitentiaries in Illinois to serve voluntarily and without any prior promise of a pardon or a reduction of sentence in prison as subjects in medical experiments. These experiments were designed to find a better preventive and curative treatment of malaria. The question has arisen of giving a reduction of sentence in prison as a reward for such service in addition to that ordinarily allowed because of good conduct.

The expression "reduction of sentence in prison" is used to indicate that under the parole system the total sentence is not reduced since the prisoner is subject to the regulations of the Parole Board after parole, his activities are supervised and the board may return him to prison. A prisoner is not subject to parole or a reduction of sentence in prison until the minimum duration fixed by court has been served in the case of sentences for an indeterminate period (e. g., ten to twenty years) when the maximum is less than life and in the case of sentences for a definite term of years but not including life.

PURPOSE OF COMMITTEE

The committee was appointed by the Governor to advise the Department of Public Safety relative to the ethical principles governing the conditions under which prisoners may be (a) permitted to serve as subjects for medical experiments and (b) granted a reduction of sentence in prison as a reward for such service.

THE ESTABLISHED ETHICAL RULES UNDER WHICH HUMAN BEINGS HAVE SERVED AS SUBJECTS IN MEDICAL EXPERIMENTS

Medical scientists, medical students, soldiers, sailors and other volunteers have on many occasions served as subjects in medical experiments designed to advance

human welfare. These experiments have been conducted according to certain ethical principles or rules in all the countries of the world which have contributed to the prevention, cure and control of disease and suffering. These rules, which have been in force by common understanding and practice, may be summarized as follows:

1. Consent of the human subject must be obtained. All subjects have been volunteers in the absence of coercion in any form. Before volunteering, the subjects have been informed of the hazards, if any.

2. The experiment to be performed must be based on the results of animal experimentation and on a knowledge of the natural history of the disease under study and must be so designed that the anticipated results will justify the performance of the experiment. The experiment must be such as to yield results unobtainable by other methods of study which are necessary for the good of society.

3. The experiment must be conducted (a) only by scientifically qualified persons and (b) so as to avoid all unnecessary physical and mental suffering and injury and (c) only after the results of adequate animal experimentation have eliminated any a priori reason to believe that death or disabling injury will occur. If there is any a priori reason that accidental death or disabling injury may occur, as in such experiments as those of Walter Reed in which the mosquito was demonstrated to transmit yellow fever, then medical scientists should serve or should have served as volunteers along with nonscientific personnel.

These rules have been adopted in essence by the House of Delegates of the American Medical Association.¹

An example of human experiments which were ideal because of their conformity with the foregoing ethical rules are the experiments at Stateville.

HISTORICAL BACKGROUND FOR USE OF PRISONER VOLUNTEERS

A historical background for the use of prisoner volunteers as subjects in medical experiments exists.² The matter of reward for such service may be summarized as follows:

In one experiment a pardon was offered as a reward prior to the starting of the experiments; in another experiment, a definite reduction of sentence prior to starting the experiments was offered, and in other experiments a reduction in sentence before starting the experiment was not promised but a reduction in sentence was considered and allowed in relation to each individual case (New Jersey and Illinois).

In this connection it would seem likely that reduction of sentence having been allowed, such reduction of sentence may be known to prisoners and that whether it is or is not stated in the contract made with the volunteer, it will be operative in his mind and may influence his decision to volunteer.

This report has been slightly condensed for publication in *THE JOURNAL*. The members of the committee were Dr. Robert S. Berghoff, Dr. Morris Fishbein, Rabbi George Fox, Father Ralph Gallagher, Dr. A. C. Ivy, chairman, Mr. Kaywin Kennedy and Mr. Oscar Mayer.

THE PURPOSES OF IMPRISONMENT

We should emphasize the generally accepted purposes of imprisonment. There are five such purposes:³

1. Punitive or retaliative, historically the oldest purpose of imprisonment, holds that revenge is the purpose of punishment.
2. Expiative holds that some sacrifice or atonement or penance by the wrongdoer is necessary and is best fulfilled by punishment.
3. Exemplary or deterrent is to try to prevent crime by the example of punishing persons who commit crime.
4. Socioprotective is the wish to protect society from dangerous and vicious persons.
5. Reformative indicates that the purpose of imprisonment is to reform the prisoner.

THE PURPOSE OF THE PAROLE SYSTEM

A reduction of sentence in prison is now recognized under the parole system "for the purpose of encouraging and rewarding good conduct and industry"⁴ (page 39), and for "exceptional bravery or fidelity"⁴ (page 42) in a good cause. The parole law is based on the presumption that the reward of good behavior in prison and the supervision of the parolee after release from prison are reformative. The prisoner who does not cause trouble and manifests industry expiates some of his offense against society and has given some assurance that he can live lawfully.⁵ It is also presumed, at least in part, that good conduct in prison is an evidence of true reformation and not of a desire to be released from prison.

The reduction of sentence in prison under the parole system is viewed as a reward for good conduct. Service as a subject in a medical experiment is considered to be a form of good conduct.

THE OPERATION OF THE PAROLE SYSTEM

It would appear likely that a reduction of sentence in prison as a recognition for service in a medical experiment is consonant with the statutory "good time," "merit time" and "industrial credits" provisions of the parole system.

Prisoners render meritorious services in prison, such as working in a barber shop, the kitchen, the shoe shop or furniture shop, and this service is rewarded. The rendering of such service is encouraged by the warden and his administrators, and service as a subject in a medical experiment may be similarly encouraged and rewarded.

WHAT SORT OF VOLUNTEER IS ACCEPTABLE?

Since one of the purposes of the parole system is reformative, the reformative value of serving as a subject in a medical experiment should be considered. Serving as a subject in a medical experiment is obviously an act of good conduct, is frequently unpleasant and occasionally hazardous and demonstrates a type of social consciousness of high order when performed primarily as a service to society. The extent to which the service of a prisoner in an experiment is motivated by good social consciousness on the one hand and by the desire for a reduction of sentence in prison on the other is a matter for consideration in the case of each prisoner.

3. Bruce, A. A.; Burgess, E. W., and Harno, A. J.: *Parole and the Indeterminate Sentence*, Parole Board of the State of Illinois, 1928.

4. *Rules and Statutes Relating to Parole and Pardons*, Department of Public Safety, Division of Correction, September 1944.

5. Act of March 19, 1872, State of Illinois. See also, Act establishing Department of Public Welfare as amended in 1927. *Progressive Merit System*, Parole Board of the State of Illinois, March 1, 1920. Bruce, Burgess and Harno.³ Footnote 4.

Regardless of a prisoner's motives for volunteering for an experiment, a habitual criminal or a prisoner who has committed a notorious or heinous crime should not be considered an acceptable volunteer for a medical experiment.

THE REWARD SHOULD NOT BE EXCESSIVE

The most important requirement for the ethical use of human beings as subjects in medical experiments is that they be volunteers. Volunteering exists when a person is able to say "yes" or "no" without fear of being punished or of being deprived of privileges due him in the ordinary course of events.

A reduction of sentence in prison, if excessive or drastic, can amount to undue influence. If the sole motive of the prisoner is to contribute to human welfare, any reduction in sentence would be a reward. If the sole motive of the prisoner is to obtain a reduction in sentence, an excessive reduction of sentence which would exercise undue influence in obtaining the consent of prisoners to serve as subjects would be inconsistent with the principle of voluntary participation.

It is not considered a function of this committee to determine where the reward becomes excessive. This is a matter to be considered in relation to each prisoner and the nature of the experiment.

Obviously no one may make representations to a prisoner concerning the extent and types of reward which may accrue as a result of his service as a subject in a medical experiment.

SUMMARY

The ethical principles most pertinent to the present consideration are (1) that all subjects should be volunteers in the absence of coercion in any form; (2) before volunteering, they be adequately informed of the hazards, if any, and (3) that the choice of volunteers be made on the basis of established criteria.

There exist a number of precedents for the reduction of sentence in prison of prisoners who have served as subjects in medical experiments. A reduction of sentence in prison for serving as a subject in a medical experiment may be considered favorable to the reformative purpose of imprisonment. Authorities agree that a reduction in sentence in prison under the parole system is a reward for good conduct and it is rational that a prisoner should earn "good time," "merit time" or "industrial credits" by serving as a subject in a medical experiment. However, it would seem self evident that any prisoner considered unlikely to become a law-abiding citizen, or who has committed a notorious and heinous crime, should not be considered favorable for service in a medical experiment.

Reduction of sentence for serving as a subject must not be excessive; the most important ethical requirement is that the prisoners be volunteers, and excessive reward can become undue influence or coercion and would be inconsistent with the principle of voluntary participation.

Obviously, the foregoing discussion and summarizing statements should be considered only as advisory to the Governor and his Department of Public Safety and should be acted on by the statutory authority of the state of Illinois.

It is recommended that a permanent Medical Committee be appointed to advise the Department of Public Safety regarding questions of a medical nature.

CANCER IN CHILDREN FROM BIRTH TO FOURTEEN YEARS OF AGE

HAROLD W. DARGEON, M.D.
New York

This article is the ninth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

Although it has been known and statistically recorded for many years that neoplasms in childhood result in a high mortality, only comparatively recently have cancer and related diseases received attention as an important child health problem. In the last decade cancer, leukemia and other tumors have exceeded almost all common diseases among the causes of death in certain age groups during childhood. This high mortality ratio is probably mainly due to the decline in deaths from other diseases. The increasing recognition and more accurate diagnosis of the neoplasms of childhood have likewise raised the statistical incidence.

Among the causes of childhood mortality in 1942 in the United States cancer and allied diseases stood tenth in the 2 year age group; third, from 3 to 10 years of age and sixth, from 10 to 14 years of age. In New York in the three year period 1942 to 1944 the deaths from neoplastic diseases during childhood exceeded those from all forms of tuberculosis (fig. 1). Wider recognition of this high mortality would stress the need for greater effort toward the establishment of early diagnosis of neoplasms in children.

It is well known that there are many types of cancer which are curable notwithstanding the present limited knowledge of the disease. An increasing number of survivals for five and ten years after treatment is being

Fig. 1.—Mortality statistics for the years 1942, 1943 and 1944, compiled by the Bureau of Records and Statistics, Department of Health, New York, show a significant decline in deaths from communicable diseases, with deaths from tumors exceeding many of them.

reported. Although certain tumors (medulloblastomas and lymphomas, for example) have a consistently unfavorable prognosis, there is encouragement in reliable reports of long periods of survival among children who have had many of the other varieties of cancer:

intracranial tumors, osteogenic sarcoma, retinoblastoma and sarcomas of soft somatic structures, that is, fat, nerve and muscle. A child patient at Memorial Hospital, New York, who had a reticulum cell lymphosarcoma has lived for seven years without clinical recurrence.

Parents often remark that treatment for their child was not sought earlier because they had supposed that

Fig. 2.—Mortality statistics for the United States, 1939 to 1943 inclusive, compiled by the United States Chamber of Commerce, show that many of the childhood deaths from tumors occur during the first five years of life. The exact figures for Hodgkin's disease are not available.

cancer was always fatal in a child. The prognosis is often unfavorable, but a constantly hopeless attitude in the presence of cancer in a child is not justified. A particularly important age group in which reduction in the death rate might be realized is that from birth to 5 years of age. Not only do the largest number of deaths, by five year age groups in children, occur in the age period from birth to 5 years of age (fig. 2) but also a large number of the curable types of cancer¹ are found in the preschool child. Increased vigilance in this group should bring many children under observation in time to effect a cure.

Cancer of the breast, uterus and ovaries in the female and cancer of the stomach, intestines and prostate in the male, which comprise such a large group of neoplasms in the adult, are so infrequent as to be curiosities in the juvenile group. Most types of tumors present in children are seldom observed after maturity, although they have been described in the adult.

Studies² of large series of cases indicate that there are six sites most frequently affected by cancer in children: (1) the bones; (2) the kidneys; (3) the eye and orbit; (4) the lymphatic and blood-forming organs; (5) the soft somatic tissues, and (6) the nervous system.³

TUMORS OF THE BONES

Varieties of Osseous Tumors.—The benign varieties of osseous tumors include bone cyst, osteochondroma, giant cell tumor and the recently described⁴ osteoid osteoma. These are observed not infrequently in pediatric and orthopedic clinics. Initially benign types of osseous tumors, such as osteochondroma and giant cell tumors, may become cancerous.

The cancers are preponderantly osteogenic sarcoma and endothelioma, or Ewing's tumor (fig. 3). The types of cancers of the bone observed among children under 15 years of age on the Bone Service and Pediatric Service at Memorial Hospital from 1921 to 1946 were predominantly osteogenic sarcoma, of which there were 72 cases, and endothelioma, of which there were 50 cases. There were 15 tumors of miscellaneous types.

Osteogenic sarcoma occurs principally in the humerus, femur and tibia and less frequently in other long bones and flat bones. Endothelioma more frequently affects the long bones than the flat bones.

The bones may be involved by direct extension of an adjacent tumor of the soft part. The bones are also demonstrably affected in leukemia as well as in metastatic cancer, such as in neuroblastoma, retinoblastoma and embryonal carcinosarcoma of kidney (Wilms' tumor). Osseous involvement may also occur

Fig. 3.—P. P., a girl aged 7 months; endothelioma of femur with pathologic fracture (patient of Dr. Bradley Coley).

as part of the constitutional anatomic alterations of neurofibromatosis.

Diagnosis of Tumors of the Bone.—Osteogenic Sarcoma: There may be pain, impaired function, fever and swelling of the affected part in osteogenic sarcoma, but not all these symptoms are present in every case. The roentgenogram in some instances is difficult to interpret, and the growth may be confused with osteomyelitis or other osseous neoplasms. If any doubt exists a biopsy is indicated. An aspiration biopsy is often sufficient, but at times a formal biopsy is necessary.

Endothelioma (Ewing's Tumor): Pain is common in an endothelioma. Fever, swelling and impairment of function may also occur. The roentgenographic appearance of the growth is subject to a wider variation than is found in any other type of primary osseous tumor.⁵ A biopsy is therefore necessary in all cases.

In general the diagnosis of tumors of the bone must be made by exclusion. There are no pathognomonic

signs early in the disease, and even when the disease is moderately advanced differential diagnosis may offer difficulties. As is well known, the disease is insidious and frequently occurs in the growing child. The active growth of the child may interfere with the early subjective and objective indications of the disease which would be recognizable in the adult who has attained his maximum development.

Up to the age of at least 6 years the child makes relatively few complaints. Trauma, sometimes even severe injury, infections and other disorders are apparently accepted by the young child as part of his existence and are forgotten in a surprisingly short time after their occurrence. Therefore the diagnosis of disease in the preschool period, and frequently later, must usually be made by objective evidence. It is obvious that the symptoms should be thoroughly investigated when a child complains, especially if the pain or disability is constant or periodic.

There are two clinical observations, not flawless but helpful, which are applicable to the diagnosis of any childhood neoplasm, including that of cancer of the bone: (1) the unusual child; (2) the atypical symptom complex. The child who differs in appearance from his fellows or whose appearance, growth or physical capacity varies from that recognized as his average or normal state may have a neoplasm. An illness that fails to follow the usual clinical course either initially or subsequently may be cancer.

The usual diagnostic methods of history-taking, physical examination, roentgen examination, biopsy and blood analysis are usually sufficient to indicate the possibility of the presence of cancer of the bone.

Differential Diagnosis.—There are certain conditions encountered chiefly in childhood which should be considered in the differential diagnosis of osseous tumors: (1) infectious disorders; (2) noninfectious systemic disorders; (3) orthopedic defects; (4) traumatic masses; (5) nonosseous neoplasms; (6) metastatic neoplasms, and (7) tumors of the central nervous system.

The infectious group includes (a) rheumatic infections; (b) pyogenic osteomyelitis, both acute and chronic; (c) tuberculosis, and (d) syphilis. The non-infectious group includes (a) scurvy; (b) sickle cell anemia, and (c) xanthomatosis.

The disorders to be differentiated from tumors of the bone in children are herewith considered separately:

1. Infections to Be Differentiated from Tumors of the Bone: (a) Rheumatic infections: The pains associated with a tumor of the bone may be confused with the myalgias and arthralgias (growing pains) of rheumatic infection. In frank cases of rheumatic fever no problem arises, but in low grade rheumatic infections considerable difficulty may be experienced. The primary roentgenograms of the bones may be normal in appearance, and no clinical or laboratory evidence suggestive of rheumatic infections may exist. Neoplasms, however, cannot be ruled out initially. A therapeutic test of salicylate administration may reduce the symptoms of pain from tumor as well as from infection. Close observation is important in such cases and calls for periodic rechecking of clinical, laboratory and roentgenographic observations.

(b) Pyogenic osteomyelitis: In acute pyogenic osteomyelitis a history of sudden onset is usually helpful in diagnosis. The objective signs, the presence of

5. Coley, B. L., and Petersen, R. L., in Dargeon.²⁴

fever, the blood count, the blood culture and the roentgenograms—all are of assistance.

In chronic pyogenic osteomyelitis the history may or may not be of aid. The physical symptoms may also suggest a tumor. The roentgenograms do not always positively differentiate the two conditions, and histologically the diagnosis may be uncertain. A high alkaline phosphatase determination may suggest the possibility of a tumor. The pathologist's report with regard to sections of tissue is especially important in diagnosis. Usually the diagnosis can be made by an evaluation of all available measures, but infrequently it cannot.

CAUTION: If any doubt exists clinically as to the nature of the disease, radiation therapy should not be administered until after further observation.

(c) **Tuberculosis:** Tuberculosis of bone may resemble a neoplasm, particularly if tuberculous granulomas exist. The history, the roentgenograms of the lungs as well as of affected sites and a biopsy will generally clarify the situation. A weak Mantoux test (0.00001 mg.) may be performed.

(d) **Syphilis:** In the presence of syphilis osseous changes are usually noted in infancy, a period in which primary tumors of bone are rare; however, syphilis can roentgenographically simulate osseous tumors of many varieties. The maternal history and serologic tests in addition to the clinical symptoms and serologic examination of the child usually serve satisfactorily to differentiate the disease.

2. **Noninfectious Systemic Disorders:** (a) **Scurvy:** Scurvy rarely occurs after infancy. The two processes, osseous tumors and scurvy, may be differentiated by clinical evidences of the disease: gingival and cutaneous hemorrhage, multiplicity of osseous involvement, diminished capillary resistance and the usually prompt response to ascorbic acid therapy.

(b) **Sickle cell anemia:** There are severe crises in which extreme pain in the bones may be experienced in sickle cell anemia. Studies of the moist blood film will reveal the typical cells. There is also a positive indirect van den Bergh reaction and a high icterus index in this disease. It occurs almost exclusively in the Negro.

(c) **Xanthomatoses and other systemic diseases with osseous involvement:** Xanthomatoses such as Niemann-Pick disease, Tay-Sachs disease, Hand-Schüller-Christian disease and Gaucher's disease usually may be positively diagnosed, if not by clinical observations then by the presence of the characteristic cells in the biopsy specimen and by the studies of the sternal marrow.

3. **Orthopedic Defects:** The pain and disabilities of orthopedic disorders, either acquired or congenital, are not always easy to differentiate from those produced by tumors of the bone. This is particularly true in the young child. If improvement does not result after the indicated corrective measures have been taken, serial roentgenograms should be continued as a diagnostic safeguard against the possibility of cancer.

4. **Traumatic Masses:** Swellings of subcutaneous tissue secondary to injuries may infrequently cause discomfort or severe pain, but sometimes the masses are hard and relatively immovable. The history, the regression of the mass and the normal roentgenographic appearance will eliminate tumor in the diagnosis.

It is important to observe closely any swelling that is believed to arise from trauma but does not disappear within a reasonable time. Serial roentgenograms must

be taken and a biopsy performed if doubt as to the cause persists. The "silent" swelling attributed to trauma may be cancer.

5. **Nonosseous Neoplasms:** The bones may be involved by locally invasive tumors (liposarcoma, fibrosarcoma or myxosarcoma) in which the soft part component is usually conspicuous, but a biopsy may be required.

6. **Metastatic Neoplasms:** Neuroblastomas, retinoblastomas, lymphomas (Hodgkin's disease, lymphosarcoma and leukemia) not uncommonly exhibit involvement of the bones (fig. 4). There is usually clinical evidence of a primary site which is not in bone. Characteristics of the peripheral blood and sternal marrow are usually pathognomonic in the leukemias. Metastasis in bone from Wilms' tumors occurs but is rare. The primary intrarenal tumor is evident enough to clarify the diagnosis.

Fig. 4.—M. O'N., a girl aged 19 months; metastatic neuroblastoma.

7. **Tumors of the Central Nervous System:** Although it is unlikely that a diagnosis of local tumor of bone would be entertained without more evidence than pain or disability of an extremity, the possibility of referred pain to an extremity from a cord tumor is to be considered in the presence of such clinical symptoms.

Treatment of Osseous Tumors.—No generalization may be made for as large a variety of tumors of the bone as occur in children. With few exceptions, surgical treatment, often radical, is indicated.

For osteogenic sarcomas amputation of the affected leg or arm is still the recommended procedure. A course of radiation therapy is given preoperatively by some surgeons.

Prognosis.—Cancers of bone share a high mortality rate with other types of cancer which occur in the juvenile period. It is probable that this rate could be lowered. There are verified cases in the Bone Sarcoma Registry and Children's Tumor Registry of survival of children for ten years after treatment for cancer of the bone.

TUMORS OF THE GENITOURINARY TRACT

In tumors in children the genitourinary structure involved most frequently in both sexes is the kidney. In the male the testes and prostate-vesical-neck region are occasional sites of neoplasms. In the female the ovary and vagina are infrequently affected.

Fig. 5.—E. St. G., a girl aged 4½ years; Wilms' tumor; the retrograde pyelogram shows dislocation and distention of renal pelvis and calices.

*Embryonal Adenomyosarcoma of Kidney (Wilms' Tumor).*⁶—Wilms' tumor is one of the more commonly observed tumors throughout the childhood period. It occurs chiefly in the child between 4 months and 4 years of age; but it may be found at any age in childhood and into maturity and as late as the sixth or seventh decade. It is an embryonal tumor which originates early in fetal life, and it is seldom observed at birth⁷ (figs. 5 and 6).

The multiple types of tissue that the tumor may contain—muscle, fat, nerve, glands, cartilage, bone, glomeruli and tubules—suggest that it is better to consider the disease as a large group of neoplasms termed Wilms' tumors than as a single entity; in this way the course, the prognosis and the variability of end results are better understood.

Diagnosis: A mass in the abdomen or flank is usually the first indication of the disease. Symptoms of intra-abdominal pressure, such as constipation, distention, pain and indigestion, do not occur early. Hematuria or other urinary disorders are seldom present. The pyelogram reveals a dislocation of the kidney pelvis, usually downward or upward depending on the location of the tumor within the kidney. The calices and pelvis are distorted. Although most Wilms' tumors are not observed roentgenographically to extend beyond the vertebral column, some do appear to extend beyond the vertebral column; therefore this observation is not always of diagnostic significance.

Differential Diagnosis: Tumors of the genitourinary tract must be differentiated from splenomegaly and hepatomegaly; hydronephrosis; the distended abdomen

of megacolon; celiac disease; tuberculous peritonitis and many other tumors, including polycystic kidney and the lymphomas (lymphosarcoma, leukemic infiltrations and Hodgkin's disease); neuroblastoma; ganglioneuroma; myosarcoma; adrenal tumor; teratoma; pheochromocytoma, and mesenteric cyst. Most of these are readily differentiated by the history and clinical manifestations.

It is seldom that at least a tentative diagnosis of Wilms' tumor is not established preoperatively. Because the tumor is usually highly malignant biopsy is contraindicated.

Treatment: Surgical excision is performed as soon as possible. The large size of some of these tumors may increase the technical difficulties of removal. If this is the case, roentgen therapy usually, not always, will reduce the size of the tumor and is recommended by some surgeons. Postoperatively the site that the tumor occupied is irradiated.

Prognosis: There are many known cures of Wilms' tumors. There is no accurate way of knowing what the percentage of cures is, but the number of deaths from this disease is undoubtedly considerably higher than the number of cures. The conflicting reports of results probably reflect the variability of the inherent nature of Wilms' tumors as well as of the time which elapsed before the institution of treatment.

Tumors of the Testis.—Tumors of the testis are unusual and are mostly teratoid in nature. Their consistency varies, and they must be differentiated from hernia and hydrocele. They require immediate excision, and sometimes surgical treatment should be preceded by irradiation.

Tumors of the Vesical Neck and Prostatic Region.—The exact origin of many tumors of the vesical neck

Fig. 6.—M. F., a boy aged 2½ years; Wilms' tumor, left: the mass contained a great deal of cartilage.

and prostatic region is difficult to determine histologically. The tumors produce symptoms of obstruction. They are usually myosarcomas and are not of frequent occurrence. Treatment has been unsatisfactory, inasmuch as surgical excision is usually impossible. Irradiation has not been effective except as a palliative measure.

7. Wells, H. G.: Occurrence and Significance of Congenital Malignant Neoplasms, Arch. Path. 30:535 (Aug.) 1940.

Ovarian Tumors.—Ovarian tumors are uncommon but are observed in the young child as well as in the adolescent. Teratomas, cysts, carcinomas, granulosa cell tumors and dysgerminomas have all been observed. The diagnosis is suggested by the presence of a pelvic mass which frequently causes constipation. Tumors that produce hormones often cause striking alterations in somatic and sexual development. The prognosis depends on the type of tumor and the promptness of treatment. Surgical removal of the tumor is required.

Myosarcoma of the Vagina.—Myosarcoma of the vagina is a rare tumor, but its presence should be suspected when a girl at any age from infancy through adolescence has a persistent bloody vaginal discharge. Treatment is by surgical removal of the tumor followed by irradiation. The prognosis is usually poor, perhaps because of delayed diagnosis.

TUMORS OF THE EYE AND ORBIT

Retinoblastoma (Glioma Retinae, Retinal Neuro-epithelioma).—Retinoblastoma arises from the granular layer of the retina and could be included histogenetically under tumors of the nervous system. It appears to have been one of the earliest described⁶ cancers in children. Many cases are recorded in the literature. It is seldom observed after the fifth year and most frequently occurs during infancy (figs. 7 and 8). The

Fig. 7.—R. W., a boy aged 3 years; retinoblastoma: the pupil is dilated, the globe of normal size.

hereditary nature of this tumor has been indicated by several authors including Wells,⁷ who has stated: "The hereditary factor seems to be particularly important in tumors of the retina as compared with tumors of other nerve tissue."

In more than half the 48 cases at Memorial Hospital the retinoblastoma was bilateral. There may be an interval of some years before the second eye becomes affected, although usually it is evident when the patient is first examined or within several months thereafter.

Diagnosis: The tumor is diagnosed by the presence of a peculiar pupillary reflex (gray, green, white, glassy, red); the dilated pupil; squinting, and visual impairment because of which the child turns his head to use the good eye. There is apparent awkwardness in the use of the arms, and if the child is old enough to walk he stumbles and runs into objects.

Differential Diagnosis: Retinoblastoma is to be differentiated from other congenital ocular lesions, such as cataract, coloboma and tunica vasculosa lentis (retrolental fibroplasia). These anomalies are often associated with other defects: the globe may be microphthalmic, and the pupil may be contracted rather than dilated.

Retinoblastoma must also be differentiated from infections, such as pseudoglioma (organized exudate in

the vitreous), confluent tubercle, retinitis and histoplasmosis. The usual associated clinical characteristics and the history, both prenatal and postnatal, will aid in differentiation.

Treatment of Retinoblastoma: If the disease is unilateral, prompt enucleation of the eye must be accomplished. If bilateral, the eye that is more involved is

Fig. 8.—R. F., a boy aged 9 years; tunica vasculosa lentis; the pupil is contracted, and microphthalmia is present.

removed. The decision with regard to the remaining eye requires fortitude on the part of the parents. They may choose to have it removed or may prefer to have it treated by irradiation. No generalities are suitable in this disease, and each case must be decided as an individual problem.

Prognosis: Among 9 patients with bilateral retinoblastoma treated at Memorial Hospital by surgical means and by irradiation, 6 survived five years or longer, 2 with vision.⁹

The course of the disease may progress regardless of the type of treatment, and if it is unchecked it generally results in widespread metastases. Late radiation sarcoma has been observed after radiation therapy for retinoblastoma.⁹

Orbital Sarcoma.—Orbital sarcomas may be observed in early infancy as well as later in childhood. They arise from any soft orbital tissue, frequently from muscle tissue (fig. 9).

Fig. 9.—C. S., a girl aged 6 weeks; orbital sarcoma.

Diagnosis: The progressive or persistent orbital swelling with or without proptosis or conjunctival changes should be considered as a possible tumor.

Treatment: The tumor and globe are removed. Irradiation is often used postoperatively.

Prognosis: Most of the orbital sarcomas are highly malignant and have an unfavorable prognosis.

TUMORS OF LYMPHATIC AND BLOOD-FORMING
ORGANS

Leukemia, lymphosarcoma and Hodgkin's disease are included among the neoplasms of lymphatic and blood-forming organs observed in children. Mycosis fungoides is also classified among these diseases, but

Fig. 10.—A. A., a girl aged 12 years; reticulum cell lymphosarcoma; she has survived seven years following the surgical removal of the tumor.

it is of doubtful occurrence in the age period being considered.

Leukemia.—Leukemia is one of the principal causes of death from neoplastic diseases in children. The diagnosis can seldom be made early, because there may be no symptoms or signs and the peripheral blood may be normal. The classic signs of adenopathy, splenomegaly, hepatomegaly, purpura and pathognomonic evidence in specimens of peripheral blood are indications of advanced disease.

Leukemia frequently simulates other diseases, such as respiratory infections and adenitis. Large leukemic infiltrations in the thorax or abdomen may suggest tumors of other histologic varieties. It has long been recognized that in many patients whose biopsy was believed to indicate a lymphosarcoma there may subsequently develop the hematic characteristics of leukemia. Since the use of antibiotics and the resultant prolongation of the lives of many patients with leukemia by the prevention of death from intercurrent infection, such instances will probably be more widely noted. From Jan. 1, 1946 to June 1, 1947 there were 5 children treated in the Pediatric Service at Memorial Hospital who had a biopsy diagnosis of lymphosarcoma. In 4 of these, the studies of the peripheral blood or the sternal marrow revealed evidence of leukemia.

Acute leukemia is the usual variety of the disease in children. Because of the difficulty of distinguishing between the immature cells of the myeloid or lymphoid group, more detailed classification is usually omitted. Chronic myeloid leukemia occasionally occurs in childhood, but it is doubtful that chronic lymphatic leukemia does. Another rare variety is eosinophilic leukemia.

Diagnosis: The clinically diagnostic features of this disease are well known. The peripheral blood in acute forms of leukemia exhibits anemia; leukocytosis (which is common but variable) and, somewhat less often, leukopenia; thrombocytopenia; young polymorphonuclear cells, and numerous mononuclear cells of the nongranular variety.

The most satisfactory and accurate aid in the diagnosis, the differential diagnosis and the study of remissions and course of the disease is the examination of the sternal marrow smear. This procedure¹⁰ is valuable and should be included in the investigation of any obscure or undiagnosed disorder.

Roentgenograms at times reveal periosteal reaction and osteolytic defects, but more commonly they exhibit only an area of rarefaction below the diaphyses of the tibia and femur.

Treatment: The use of radioactive isotopes in leukemia in children at Memorial Hospital did not give encouraging results and has been discontinued. Urethane was used in 2 cases. A more palliative effect was noted in 5 patients in whom nitrogen mustard was used. Many institutions throughout the world are pursuing clinical investigations with these and other chemicals, but the results cannot be completely evaluated at this time.

Hodgkin's Disease.—The clinical appearance of large masses of lymph nodes, particularly in the neck, axillas and inguinal regions in Hodgkin's disease is well known.

Diagnosis: The diagnosis must be made by biopsy.

Differential Diagnosis: Adenopathy from infectious causes as well as from other types of tumors must be

Fig. 11.—M. G., a girl aged 4 months; extensive hemangioma of face; the distribution is almost completely right-sided.

differentiated from Hodgkin's disease. Difficulty may be experienced in histologic differentiation between lymphosarcoma or benign lymphoma and Hodgkin's disease.

10. Smith, C. H.: Bone Marrow Examination in Blood Disorders. *M. Clin. North America* 31:525 (May) 1947.

Prognosis: Hodgkin's disease terminates fatally, but palliative roentgen therapy is possible and may prolong life for several years.

Lymphosarcoma.—During childhood lymphosarcoma occurs oftener in the tonsil, nasopharynx and lymph nodes than in other lymphatic structures.

Fig. 12.—A. S., a girl aged 6½ years; rhabdomyosarcoma of the thumb; the tumor has been present since infancy.

Diagnosis: Persistent adenopathy or intrathoracic and intra-abdominal masses indicate that a biopsy is required.

Differential Diagnosis: The difficulties in the histologic differentiation of a lymphosarcoma from other varieties of lymphoma and at times from neuroblastoma are familiar to most pathologists.

Treatment and Prognosis: The prognosis is generally unfavorable. It is believed that if the tumor is localized and can be surgically extirpated the prognosis might be improved. One child treated in this way at Memorial Hospital has survived more than seven years (fig. 10).

TUMORS OF SOFT SOMATIC STRUCTURES

Hemangioma.—One of the commonest tumors observed in white children, although extremely rare in the Negro, is the hemangioma.

Diagnosis and Differential Diagnosis: The hemangioma may be diagnosed readily if it is cutaneous in location. If it is subcutaneous, visceral or osseous, the tumor must be differentiated from other tumors and nonneoplastic disorders of those sites.

Visceral hemangiomas occur at times in association with cutaneous lesions. Infrequently they are present in the absence of external lesions, and it is therefore important to realize that death may result from hemorrhage, pressure or serious interference with function in the locality affected even though tumors are not externally evident.

Treatment of Hemangiomas: The practice of waiting for spontaneous or traumatic thrombosis to produce regression is not invariably satisfactory. Although many hemangiomas regress in this manner, some may

produce severe disfigurement (fig. 11) or serious functional defects if they are permitted to grow.

The development of hemangioma in an infant during the first few weeks of life requires close, almost daily, supervision to estimate the rapidity of growth. Usually hemangiomas which appear in this early period rapidly increase in size. This may be due not so much to growth of the tumor as to the gradual engorgement of a neoplasm whose pattern was established prenatally.

Cauterization with carbon dioxide snow is a simple and satisfactory method of treating many capillary hemangiomas. Surgery and radiation therapy may be required for the treatment of certain hemangiomas, particularly of the cavernous, racemous and hypertrophic varieties.

Lymphangioma.—Lymphangioma is not common. It is usually observed in its soft cystic form in the neck or thoracic region (hygroma cysticum coli). It may also diffusely infiltrate to the subcutaneous tissue or appear in the skin itself as localized cysts. Mesenteric cysts are of lymphangiomatous nature.

Surgery appears to offer the best prognosis. The operative problem in some cases of hygroma, however, is formidable.

Tumors of Fat, Muscle and Nerve.—Tumors may arise in any subcutaneous structure. They appear usually as painless, silent swellings and therefore in many cases are considered to be hematomas. With few exceptions any nontraumatic swelling should suggest

Fig. 13.—V. S., a boy aged 1½ years; lipoma, an uncommon tumor in childhood: a small mass was noted at 7 months; the mass grew to the size illustrated within eleven months.

cancer. Any traumatic swelling that does not regress in the usual time and manner should be considered to be cancer unless clinical characteristics or, preferably, biopsy results prove otherwise. A solid tumor may be transilluminated almost as well as a cyst.

Operative removal of the tumor is the recommended treatment.

TUMORS OF THE NERVOUS SYSTEM

Neoplasms of the brain, intracranial structures, sympathetic nervous system, spinal cord and peripheral nerves comprise a large group of common benign and malignant tumors.

Intracranial Tumors.—As might be expected, there are many histologic varieties of intracranial tumors.

Fig. 14.—K. S., a boy aged 7 years; severe hydrocephalus from effects of cerebellar astrocytoma.

The commonest are the astrocytoma, medulloblastoma, craniopharyngioma, meningioma and ependymoma. The tuberculoma is encountered in the United States with diminishing frequency.

In children most intracranial tumors are subtentorial, whereas in the adult supratentorial growths predominate numerically. The symptoms produced depend on the site affected and the degree of intracranial hypertension produced. This seems obvious until it is recalled that in the infant and young child the easily expandable head may permit a tumor to develop for a prolonged period before any signs or symptoms are evident.

The symptoms of intracranial hypertension are familiar: headache, vomiting (especially early morning or unrelated to ingestion of food); sometimes nausea, papilledema, and Macewen's sign (cracked pot resonance on percussion of the skull). In what might be considered the initial phases of the disease diagnosis is difficult. The earliest indications are slight and are usually forgotten by the parents or patient until memories are refreshed some time after the diagnosis has been made.

Tumors of the Posterior Fossa.—Tumors of the posterior fossa are most frequently medulloblastoma or astrocytoma. Ependymoma of the fourth ventricle is also not uncommon.

Cerebellar symptoms may precede or follow signs of intracranial hypertension. Such symptoms are ataxia, in which the child may walk on a wide base; vertigo, and nystagmus. Hypotonia is frequent after the disease has progressed. The knee jerks are diminished or are absent. Some involvement of the cranial nerves may be noted if compression of the brain stem occurs. If the neoplasm expands the posterior fossa, the inion

may appear on the roentgenogram to be higher than normal in relation to the atlas. Ventriculograms usually disclose dilated lateral ventricles.

Lumbar puncture should not be performed when there are indications of tumor of the posterior fossa or of intracranial hypertension from any cause.

Supratentorial Tumors: Craniopharyngioma (Rathke's Pouch Cyst).—The craniopharyngioma is one of the most frequently described intracranial tumors of childhood. It is a cystic tumor arising from the stomodaeum. Because of its location in the suprasellar region it produces a variety of symptoms.

Diagnosis: In addition to the symptoms of intracranial hypertension, which are almost always present, visual difficulties and optic atrophy, hemianopsia and somatic changes, such as obesity, pubertas precox and infantilism, are of frequent occurrence. Psychic changes are not uncommon.

The diagnosis may almost always be confirmed with certainty if roentgenographic evidences of separation of the sutures, increased definition of digital markings, crystalline shadows in the suprasellar areas and, frequently, destruction of the clinoid processes are demonstrable.

Differential Diagnosis of Intracranial Tumors: (1) Congenital hydrocephalus is usually present at birth and is progressive. (2) Subdural hematoma and (3) pachymeningitis hemorrhagica are diagnosed by aspiration of the contained serous or serosanguinous fluid. (4) Encephalitis may be difficult to diagnose if the evidence is inconclusive. Repeated investigations may be necessary before the possibility of tumor can be excluded. (5) Lead encephalopathy is also at times difficult to differentiate. The lead lines observed in the bones roentgenographically and occasionally the history are helpful. The gingival condition is usually normal, and there is frequently no basophilic stippling of the red cells, or anemia. The urine will contain lead in quantitatively significant amounts.

Fig. 15.—M. B., a girl aged 3½ years; neuroblastoma: the primary tumor was a dark nodule near the right nasolabial fold.

Because of the many types of cerebral structures affected by neoplastic diseases, many erroneous diagnoses are made. Principal among these are gastrointestinal disorders, behavior problems and chorea.

Treatment: Surgery is indicated in almost all intracranial tumors. Tumors of the brain stem are inoperable. Irradiation is used postoperatively in

medulloblastoma and sometimes in certain nonmalignant varieties, such as hemangioma.

Prognosis: Although the craniopharyngioma is histologically benign, the prognosis must be guarded because of the proximity to important cerebral structures.

Approximately one third of all intracranial tumors in childhood are curable if treatment is instituted before irreparable injury to the brain has occurred.¹¹

Tumors of the Spinal Cord.—Tumors of the spinal cord are uncommon in childhood. The tumor may arise outside of the cord and affect it either by invasion or by pressure. Many types are described: sarcomas, dermoids, lipomas and neurinomas.

Diagnosis: The symptoms are usually bilateral, but not invariably so. The symptoms at the level of the lesion are segmental pain and other sensory disturbances. Muscular atrophy may also occur. The signs below the level of the disease consist of both motor and sensory disorders which become progressively worse until little motor activity is present and sensation is completely lost.

The spinal fluid is often yellow and may clot on standing. Jugular compression does not increase the pressure of the spinal fluid. Roentgenograms, particularly by means of myelography, will often show the lesion.

Differential Diagnosis: Chorea, poliomyelitis, tuberculous spondylitis and the Guillain-Barré syndrome have been confused with cord tumors but may be differentiated by the usual confirmatory characteristics in the presence of these diseases.

Treatment: If feasible, surgical removal is the treatment. Palliative irradiation is indicated for lymphomas and extradural sarcomas.

Sympathetic Nervous System: Neuroblastoma.—The neuroblastoma is one of the more frequently observed cancers of the nervous system. It arises from the sympathetic neuroblast. The most commonly described site is the adrenal medulla, but it is probable that this is only one of many primarily involved tissues. Thirty-eight cases in children have been observed at Memorial Hospital. In 12 of these the sites of the primary tumors were believed on autopsy to be as follows: adrenal, 8; cervical sympathetic chain, 1; right sciatic nerve, 1; presacral area, 1, and periorbital tissues, 1.

Diagnosis: Unfortunately, a neuroblastoma is seldom recognized before it has metastasized to the skull, liver, lungs or bones, because the primary site may be small. Although clinical and roentgenographic observations may be suggestive, biopsy is necessary.

Differential Diagnosis: In some instances it is not easy to differentiate between neuroblastoma and lymphosarcoma. Neuroblastoma is to be considered in the differential diagnosis of any mass in the flank or the posterior mediastinum. In 1 case it was observed that the primary site was apparently the cheek, and in another the thigh was first affected.

Treatment: Treatment is by extirpation of the primary tumor, and by radiation if metastases are not extensive.

Prognosis: There have been some cases reported¹² of survival five years after treatment. Usually, however, the prognosis is grave.

Ganglioneuroma.—The ganglioneuroma is a benign tumor which has been noted in early infancy as well as in the run-about child. It usually is found intrathoracically or retroperitoneally. It may reach huge proportions.

Diagnosis: In the diagnosis of any posterior mediastinal or retroperitoneal mass the ganglioneuroma must be considered a possibility. Usually the existence of the tumor for a duration of months to years without the occurrence of metastases is helpful in the differentiation of neoplasms in these sites.

Treatment and Prognosis: Treatment is by extirpation. The prognosis is favorable.

Pheochromocytoma.—Pheochromocytoma is a curious and rare tumor of nerve origin and is suggested when hypertension is present with or without signs of a mass in the flank or abdomen.

Surgical removal has been attended by shock. Great care must be exercised during the operation to prevent vascular collapse.

Neurosarcoma.—Some sarcomas of the soft parts originate in the peripheral nerves. These tumors start, as do their benign counterparts, as small subcutaneous nodules which may cause no subjective symptoms and may not enlarge rapidly.

Diagnosis: The clinical diagnosis is usually made as "soft part tumor."

Treatment: The nature of most of these masses is interesting to speculate about, but the correct management demands a prompt and complete excision if this is possible. If this cannot be done a biopsy should be performed so that the diagnosis may not be doubtful.

Prognosis: There are authenticated cures of neurosarcoma.

Neurofibroma and Neurofibromatosis.—There is an extensive literature concerning this interesting group of hereditary neoplasms, neurofibromas and neurofibromatosis. The tumors may be single or multiple and may be intracutaneous or subcutaneous. The lesions associated with neurofibromatosis are numerous. Café au lait spots are usually present in quantities. Personality defects and mental retardation may also be present. One of the patients at Memorial Hospital, a boy aged 9 years, has gynecomastia and an increase in follicle-stimulating hormone.

Diagnosis: There is usually no difficulty in diagnosis when multiple stigmas are present, as they usually are in neurofibromas and neurofibromatosis. Osseous changes in the vertebral column have been observed in children who demonstrated nothing externally but a few small café au lait spots.

Treatment: Inasmuch as about 15 per cent of all neurofibromas may undergo cancerous changes, the removal of accessible tumors is indicated. The deeply situated growths, in the thorax, for example, may be so diffuse as to preclude their complete removal.

Nevi: Neuroncervus (Pigmented Mole) and Melanoma.—The pigmented mole is commonly observed. Unless it is of great size, is growing rapidly or is

11. Bucy, P. C.: Personal communication to the author.

12. Farber, S., in Nelson, W. E.: *Mitchell-Nelson's Textbook of Pediatrics*, ed. 4, Philadelphia, W. B. Saunders Company, 1946.

subject to trauma, it may be left alone. The melanoma is a cancer. Clinically malignant melanoma is exceedingly rare before puberty. Histologically cancerous alterations may begin at any time during or after puberty. Thorough removal as early in life as possible is imperative.

Teratomas, Teratoid Tumors and Dermoid Cysts.—Teratomas, teratoid tumors and dermoid cysts are complex tumors of embryonal origin, which occur at many sites: the sacrococcygeal region, the brain, thorax and abdomen.

Diagnosis: There may be little difficulty in diagnosis if the tumors occur at or near the surface of the body; however, if they are situated in a bodily cavity, they must be differentiated from any other mass which might occur at that site.

Treatment: Treatment is by surgical excision. The operative time of choice is not always simple to decide. An extensive surgical procedure cannot be tolerated by many infants. There is risk in delaying the operation inasmuch as an estimated 3 to 45 per cent of the tumors of this type are or will become cancerous.

Prognosis: The prognosis is variable, as would be expected; it depends on the histologic type, the size and the location of the tumor.

PROPOSALS FOR CANCER CONTROL IN CHILDHOOD

The need for collaboration in the study of tumors in children has been recognized by all those engaged in this field. The American Academy of Pediatrics has endorsed such a coordinated study as part of its national child health program, by the establishment of a Children's Tumor Registry. The combined experience of various clinics is required to evaluate results, incidence and diagnostic criteria, because the type of tumors observed in each hospital may vary considerably.

The satisfactory control of any disease requires the application of preventive measures, if available, or an aggressive therapeutic attack before the disease has progressed beyond the period of possible cure. Some prophylactic measures for childhood cancer are outlined in succeeding paragraphs.

The success of the methods now employed in treatment is determined not alone by the capabilities of the surgeon and radiotherapist but also by the rapidity with which they are permitted to institute treatment for a potentially curable neoplasm. Therefore the outcome of the curable case depends largely on how early it is recognized and how promptly treatment is started.

No member of the entire group of physicians concerned with the problem of cancer in children—the

surgeon, radiologist, pathologist, pediatrician or health officer—is more important than the family physician, who usually sees the patient first and whose opinion and recommendations are the basis for the family's decisions.

Therapy, with certain modifications, has been relatively standardized; consequently, many localities in the country now offer proper treatment. The current necessity is for greater attention to earlier diagnosis.

A satisfactory cancer program for children should include (1) periodic health examinations; (2) excision or biopsy of swellings as indicated; (3) excision of potentially cancerous growths; (4) systematic clinical investigations, and (5) a revision of the attitude toward benign tumors.

1. *Health Examinations.*—The periodic health examination should take place monthly from birth to 1 year of age, quarterly from 1 to 6 years and semiannually thereafter. In this examination a roentgenogram of the thorax and a complete blood count in addition to other pediatric routines should be included.

2. *Excision or Biopsy of Swellings.*—Excision preferably, or biopsy, should be done of any suggestive swelling which is (a) of traumatic origin but of unusual duration or otherwise different from the frequent hematomas of childhood or (b) of nontraumatic origin, except enlargements of organs, such as the breasts and testes, associated with the growth of the girl or boy, and gynecomastia.

3. *Excision of Growths.*—Excision of potentially cancerous growths, such as melanoma, teratoma, dermoid and neuroma, should be accomplished as soon as possible.

4. *Investigation.*—A disorder that appears to satisfy all but a few of the criteria of a common disease may be cancer. Investigation and even repeated investigations, therefore, should be routine in the presence of (a) an atypical symptom complex or (b) an unusual child patient, especially the precocious or retarded child, if the departure from his norm has been increasingly apparent or if the child has periodic vague illnesses with phases of normal health between attacks.

Observation of the child with an unusual growth or retardation of growth of the body as a whole or some of its members should suggest to the physician the possible presence of a neoplasm. The child who is a behavior problem may likewise have a neoplasm. The necessity for eliminating the possibility of organic nervous disease in behavior problems has been repeatedly stressed by psychiatrists and psychologists engaged in this field as well as by neurologists.

5. *Revision of Attitude Toward Benign Tumors.*—A revision in the attitude toward benign tumors is imperative. Any neoplasm, regardless of its histologic structure, may cause death if its size, rapidity of growth, anatomic location or interference with function seriously disturbs vital activities. There are many examples of grave benign tumors, the most striking of which are the intracranial tumors. These are for the most part histologically benign, but they involve such important structures that they result in a high mortality.

The term benign tumor is therefore in many cases prognostically misleading to the patient and at times to the physician, unless all the implications of a tumor so designated are thoroughly understood.

Clinical Notes, Suggestions and New Instruments

DEATH FOLLOWING ACCIDENTAL INGESTION OF DDT

Experimental Studies

NATHAN J. SMITH, M.D.
Wadsworth, Kan.

DDT (1,1,1-trichloro-2,2-bis[*p*-chlorophenyl]-ethane) has recently become widely used in readily available commercial insecticides. Therefore, this chemical has added to the list of protoplasmic poisons which do not produce detrimental effects when used as intended,¹ but may be extremely harmful, and even lethal, when ingested accidentally or with suicidal intent. A case of accidental fatal poisoning by ingestion of a commercial DDT preparation was observed recently, which came to autopsy six and one-half days after drinking the poison. Other instances of accidental DDT intoxication undoubtedly will occur as long as these preparations are available commercially, and thus an investigation into the toxic effects of one of these commercial insecticides should be of interest.

REPORT OF CASE

Mr. B, age 58, a white laborer, had been in good health until Aug. 1, 1946. On the afternoon of that day he drank, accidentally, 120 cc. of a 5 per cent solution of DDT. He immediately realized his error and drank a quart of milk within a few minutes after swallowing the poison. The patient then drank several glasses of beer.

Within an hour of the accident he noticed the onset of severe epigastric pain, and he vomited copious amounts of "coffee ground-like" material. These symptoms continued with increasing severity, the episodes of emesis occurring every thirty to sixty minutes for the following several hours. The vomitus varied in color from dark brown to bright red. Thirty-six hours after drinking the DDT preparation, the patient was still vomiting frequently and began having involuntary spastic contractions of his fingers and wrists.

On August 3 an osteopath was called who gave some unknown hypodermic medication and other medication to be taken every thirty minutes in a glass of milk. None of the latter was retained. His symptoms of epigastric pain, repeated emesis and some abdominal distention continued until August 6, when he was admitted to the Veterans Administration Center, Wadsworth, Kan. At the time of admission he had passed no urine since two hours after ingesting the DDT mixture six days before and had had but two tarry black stools during this time. The patient complained of thirst, but any attempt to take water by mouth was followed by an emesis of brown blood-stained vomitus.

On physical examination the patient was a small, well developed white man of 58 years who appeared acutely ill. His temperature was 99.6 F., respirations 25 per minute, and pulse rate 66 per minute. The blood pressure was 180 systolic and 72 diastolic. Other positive physical findings were confined to the abdomen and nervous system. There was some distention of the abdomen. The upper quadrants were rigid and tender to palpation, with the liver palpable 2 cm. below the costal margin at the midclavicular line. The pupils were unequal and did not react to light or accommodation. The patellar, abdominal and cremasteric reflexes were not present. No pathologic reflexes or clonus were elicited. The extremities had normal muscle tone; there were no tremors.

From the Department of Pathology, Veterans Administration Center, Wadsworth, Kansas.

The photomicrographs used in figures 1 and 2 were furnished by the Army Institute of Pathology.

Dr. F. C. Helwig, Consultant in Pathology, Wadsworth Veterans Center, Wadsworth, Kan., made many fine suggestions in the preparation of this report.

Published with permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or conclusions drawn by the author.

J. Angley, J. C.: *Air Surgeon's Bull.* 2:77-78 (March) 1945. Draize, J. H.; Woodard, G.; Fitzhugh, O. G.; Nelson, A. A.; Smith, R. B., and Calvery, H. O.: *abstracted, Bull. Hyg.* 20:213 (April) 1945.

Laboratory data at the time of admission showed the erythrocyte count to be 3,120,000 with 78 per cent hemoglobin. The total leukocyte count was 11,600. The nonprotein nitrogen was 150 mg. per hundred cubic centimeters. The patient was catheterized, and 300 cc. of straw-colored urine was obtained. The pH was 7.0, specific gravity 1.012, albumin 1 plus. The reactions for sugar, acetone and diacetic acid were negative. Microscopic study showed 3 to 8 white blood cells per high power field and an occasional granular cast.

The patient was given 1,000 cc. of 10 per cent glucose in isotonic solution of sodium chloride soon after admission on August 6. He continued to have repeated episodes of hematemesis and six hours after admission began to perspire profusely and to become comatose. On August 7 his condition had not improved. He had several black tarry stools and repeated episodes of hematemesis. He continued in deep coma and coarse moist rales developed at the bases of both lungs. The blood pressure fell to 110 systolic and 60 diastolic, and the pulse became rapid (120 per minute). The patient died at 10:15 p. m. August 7, thirty hours after admission.

Fig. 1.—The central portions of all of the hepatic lobules show extensive necrosis with complete destruction of the parenchymal cells. The few viable cells remaining about the portal areas have undergone extensive fatty degeneration.

NECROPSY

Necropsy was performed sixteen hours after death and eight hours after the body had been embalmed. The body was that of a 58 year old white man, 5 feet 4½ inches (163.8 cm.) in length, weighing approximately 120 pounds (54.4 Kg.). There was definite rigor mortis and livor mortis present. The abdomen was slightly distended.

The heart was removed and weighed 220 Gm. The coronary vessels were sectioned serially, and several large atheromatous plaques were present. The vessels were patent throughout their course. The lungs were removed and weighed 1,350 Gm. Section through the pulmonary parenchyma revealed a uniform, dark red surface from which a large amount of blood-tinged fluid exuded. The liver weighed 1,550 Gm. Its surface showed no change, but on cut section the parenchyma presented a yellow-brown surface studded with pinpoint hemorrhagic and necrotic-appearing foci. This picture was uniformly present throughout the entire organ in both right and left lobes. The stomach contained 400 cc. of thin, brown, blood-tinged fluid. The mucosa was decidedly hyperemic, with many small submucosal hemorrhages grossly visible. In the first portion of the duodenum, a well healed old ulcer was present measuring 1.5 by 2.0 by 0.5 cm. The right kidney weighed 220 Gm. Its capsule stripped with ease, and a smooth surface, pale yellow in color, was present. On section the very pale cortex con-

trasted sharply with the dark red medullary portion. The left kidney weighed 210 Gm., and it appeared similar to its fellow. The ureters were normal. The urinary bladder contained only 50 cc. of clear urine. The meninges were not altered, and the cerebrospinal fluid was clear. The brain weighed 1,420 Gm. Serial sections through the cerebral hemispheres, cerebellum and brain stem revealed no gross lesions.

Sections from representative areas of all the organs were examined, and the following changes were observed. In the lungs the alveoli were found to contain many large pigment-laden phagocytes, and in occasional areas peribronchial pneumonia was seen. A section of the myocardium showed many small areas of perivascular scarring and myofibrosis. The intima of the aorta was thickened, and in the media and adventitia changes of syphilitic aortitis were found. The liver was the site of an extreme toxic change (fig. 1). The central portions of all the lobules showed extensive necrosis with complete destruction of all parenchymal cells, leaving only a few reticular fibers, bile-stained cell fragments and occasional extravasated erythrocytes. The few viable cells remaining about the portal areas had undergone extensive fatty degeneration, with large lipid

Fig. 2.—The renal tubules are the site of extensive degenerative change. Abundant acidophilic and bile stained debris as well as hyaline droplets fill the lumen.

vacuoles in the cytoplasm of many of the cells. The cells remaining intact showed considerable variance in structure. Several small vacuoles were all that remained of the cytoplasm in some cells, while others were swollen, with a coarsely granular, deep-staining cytoplasm which often contained small deposits of bile. All were enlarged and distorted, and they varied greatly in size. The structures in the portal areas were unaltered. The kidney tubules showed extensive changes which were most conspicuous in the proximal convoluted tubules, but extensive damage, even into the distal convoluted and collecting tubules, was present (fig. 2). The tubular epithelium was the site of many types of degeneration and necrosis. The lumen of the tubules in these areas contained abundant acidophilic and bile-stained debris, with many hyaline droplets also present. With the atrophy and degeneration of the tubular epithelium, the lumen of the tubules appeared greatly enlarged with well formed hyaline and granular appearing casts frequently seen. Some evidence of regeneration of the destroyed epithelium from remaining basilar portions of the cells was seen in many areas. These severe toxic changes were found to uniformly affect all sections of the kidney. In the glomeruli the vascular apparatus was unaltered. Bowman's space contained many shreds of coagulated protein material and swollen sloughed epithelial cells. In sections from both kidneys a few small arteriosclerotic scars were found.

The final diagnosis was toxic hepatitis, toxic tubular degeneration of the kidneys, syphilitic aortitis, healed duodenal ulcer, generalized arteriosclerosis, coronary arteriosclerosis with myofibrosis, and bronchopneumonia.

EXPERIMENTAL DATA

An attempt was made to ascertain the role which DDT played in production of the lesions observed in the case reported here. The York Pharmacal Company, manufacturer of the insecticide ingested by the patient, was very cooperative and furnished samples of their product. These constituents were present in the following proportions:

D.D.T.	5 %
"Lethane" (384 special)	2 %
Xylene	7 %
Deodorized kerosene	86 %

To determine the effect of each of the four constituents in production of the specific changes found, rabbits were given doses of the insecticide and of each of the four ingredients by gastric tube. The dosage was calculated in each instance to be in proportion to the relative body weight. The animals were killed at 6.5 days, the duration of the patient's course after ingesting the poison. Below is a summary of the findings.

Two rabbits were given the original insecticide mixture. The kidneys in both animals were affected with a severe toxic tubular degeneration, and in the liver an extensive centralobular toxic change was seen. Proportionate amounts of xylol and "lethane" each were given to 2 rabbits and the animals killed in the specified time. No changes were noted in either the liver or kidneys. When a rabbit was given the calculated dosage of deodorized kerosene, many stages of tubular degeneration were seen microscopically in the kidneys, and the liver was the site of rather pronounced parenchymatous damage. Five per cent DDT in cod liver oil was given to 2 rabbits and produced a toxic tubular degeneration in the kidneys, although not as great as that seen in the animal poisoned with kerosene. The damage to the liver was more striking, however, with an actual central necrosis seen in some lobules in the liver sections. One animal poisoned with a 5 per cent solution of DDT in deodorized kerosene showed the most extensive hepatic and renal damage. In rabbits poisoned by the insecticide and in those given 5 per cent DDT in kerosene, the lesions closely simulated those noted in the patient studied.

The factor of alcohol ingestion was ignored in pursuing these studies, inasmuch as no information was available as to the amount and exact time the patient drank the quantity of beer mentioned in the history. The possibility of alcohol increasing the susceptibility of tissues to a parenchymatous poison, such as is seen in carbon tetrachloride intoxication, is a factor to be considered.

From these limited studies one would be led to believe that the commercial insecticide mixture in question contained adequate amounts of two chemicals, kerosene and DDT, to produce severe hepatic and renal damage. DDT apparently was the factor of prime importance. These studies might also suggest a possible synergistic action when DDT and kerosene are combined.

COMMENT

I have found in the literature only 2 deaths resulting from DDT intoxication. The first case, reported by Hill and Robinson,² was that of a 19 month old infant who died within four hours after ingesting 30 cc. of a 5 per cent mixture of DDT in kerosene. Terminal pulmonary edema was the only pathologic lesion demonstrable. Hill and Damiani³ reported a second case of fatal poisoning occurring in a man aged 47. Symptoms of intoxication began twenty-four hours after working in a room which had been sprayed with a solution of 6 per cent

1a. "Lethane" (384 special) is a liquid insecticide concentrate containing 12.5 per cent by volume beta-butoxy-beta'-thiocyanodiethyl ether and 37.5 per cent by volume beta-thiocyanooethyl esters of aliphatic acids containing 10 to 18 carbon atoms, standardized with petroleum distillate. A review of the toxicology of this substance by W. D. Murphy in *J. Agr. Med.* 1937, states that the substance is nontoxic in warm-blooded animals in amounts used in commercial insecticides.

DDT in kerosene. Lesions simulating periarteritis nodosa were found at autopsy. These workers suggest that DDT possesses allergic properties similar to the sulfonamide compounds and certain iodides which have been found capable of producing a hypersensitive state.

The case reported here appears to be unique in that, although the patient ingested lethal quantities of a poisonous mixture containing DDT, he lived for 6.5 days and sufficient time was allowed for the development of demonstrable lesions in the affected organs. Heretofore only in animal experiments have opportunities for the study of these changes been available. Lillie and Smith,⁴ Cameron and Burgess,⁵ Nelson and others⁶ and Woodard and his co-workers⁷ have all carried out such studies in extensive animal experiments. Animals ingesting DDT in single large doses, as well as in repeated small doses, have shown a constant histopathologic picture with hepatic and renal degeneration. The changes described are not unlike those observed in this case with a severe centrilobular necrosis and degeneration in the liver and varying types of tubular damage in the kidneys.

In addition to changes in the liver and kidney, other less constant changes have been observed in some of the animals studied. Cameron and Burgess⁵ have noted occasional fatty infiltration and even focal necrosis in some of the fibers in sections of striated muscle. Mucosal gastric hemorrhages also have been seen in some animals given large oral doses of DDT.⁶ Lillie and Smith⁴ found a partial tyroglysis with pericellular vacuolation in the anterior horn of the spinal cord in some cats in their series. However, other workers⁸ have reported no demonstrable lesion in the brain or spinal cord, and neither of the two recorded human autopsies has revealed any change in the central nervous system.

The clinical manifestations of DDT intoxication, as have been reported in nonfatal cases, are based chiefly on the neurotoxic action of the chemical.⁹ The patient studied by Wigglesworth¹⁰ suffered from extreme nervous tension, mental anxiety and heaviness and aching of the extremities. Case and his co-workers¹¹ experienced identical symptoms when they exposed themselves to DDT for forty-eight hours in a room which had been painted with a paint containing DDT. However, in the case reported here, the severe gastrointestinal symptoms and the onset of coma so predominated in the patient's clinical course that he was unable to give an account of any less striking symptoms. It was also impossible to examine the urine or feces for DDT or bis(p-chlorophenyl)-acetic acid (DDA) as had been done in animals and in one case reported by Stohlmán and Smith.¹⁰ Moreover, we did not determine the presence of DDT in any tissues or body fluids, as has been done by Stiff and Castillo.¹¹

With the increasing use of DDT insecticides by the general public, it is not unlikely that occasional cases of poisoning from its accidental ingestion will be encountered. The experience with the case reported here would indicate that degenerative lesions in the liver and kidney similar to those previously studied in animals may be anticipated.

SUMMARY

A case is reported in which a man accidentally ingested a lethal amount of a commercial insecticide containing DDT. At autopsy pronounced tubular degeneration of the kidneys and severe toxic hepatic degeneration were noted. Similar lesions were reproduced experimentally in a small series of rabbits.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statements.

AUSTIN SMITH, M.D., Secretary.

PARATHION, GENERIC TERM FOR O,O-diethyl O-para-nitrophenyl thiophosphate

At its recent meeting the Council considered a request from S. A. Rohwer, chairman, Interdepartment Committee on Pest Control of the Agricultural Research Administration, United States Department of Agriculture, concerning the acceptability of the proposed name "parathion" (pronounced pa-rá-thi-on) for the new insecticide, O,O-diethyl O-para-nitrophenyl thiophosphate. On the basis of the brief submitted by Mr. Rohwer, the Council's Committee on Nomenclature recommended that the name be declared acceptable, and the Council voted that parathion be recognized as the common, or generic, name for O,O-diethyl O-para-nitrophenyl thiophosphate.

HEXACHLOROPHENE, GENERIC TERM FOR bis(2-hydroxy-3, 5, 6-trichlorophenyl) methane

The Council considered the proposal of a pharmaceutical manufacturer for the use of the term hexachlorophene as a generic designation for bis(2-hydroxy-3, 5, 6-trichlorophenyl) methane. No objection was raised to the term, and the Council voted to recognize hexachlorophene as the generic, or common, designation for bis-(2-hydroxy-3, 5, 6-trichlorophenyl) methane.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1947, p. 57).

The following dosage form has been accepted:

BREWER & Co., INC., WORCESTER, MASS.

Solution Procaine Hydrochloride 2% with Epinephrine 1:25,000: 30 cc. vials. Each cubic centimeter contains procaine hydrochloride 20 mg., epinephrine 0.04 mg. and sodium chloride 3.7 mg. in water, with sodium bisulfite 0.1 per cent and chlorobutanol 0.5 per cent as preservatives.

ASCORBIC ACID (See New and Nonofficial Remedies, 1947, p. 517).

The following dosage form has been accepted:

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Vitamin C Drops: 15 cc. bottles with dropper. Each cubic centimeter contains 150 mg. of ascorbic acid, 0.25 cc. of water and 0.003 cc. orange oil, with equal parts of glycerin and propylene glycol.

FUNGUS EXTRACTS (See New and Nonofficial Remedies, 1947, p. 9).

The following additional extracts have been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Fungus Extracts: 2 cc., 5 cc. and 30 cc. vials.

Puccinia coronata avenae (Crown Rust of Oats); *Ustilago avenae* (Loose Smut of Oats); *Ustilago tritici* (Loose Smut of Wheat) and *Ustilago medians* (Loose Smut of Barley).

VINBARBITAL SODIUM (See New and Nonofficial Remedies, 1947, p. 420).

The following additional dosage form has been accepted:

SHARP & DOHME, INC., GLENOLDEN, PA.

Solution Delvinal Sodium: 5 cc. ampuls and 20 cc. vials. Each cubic centimeter contains vinbarbital sodium 60 mg. in aqueous 90 per cent propylene glycol solution.

SATURDAY, FEBRUARY 14, 1948

KALA-AZAR

Kala-azar, although highly endemic in the Mediterranean littoral, India and China, was not a serious military problem in World War II. Some 75 cases of the disease were recorded in the American army during the war; no doubt but few cases will be recognized in this country. The clinical course, diagnosis and treatment of kala-azar were summarized in a recent article by Major Harry Most and Capt. Paul H. Lavietes¹ on the basis of 30 patients treated for the disease at Moore General Hospital, Swannanoa, N. C., a tropical disease center. The incubation period in kala-azar has not been definitely established. The shortest incubation period in their series¹ was three weeks, and the longest, thirty-three months. The onset of the disease is characterized by abruptness, chills and high fever in the majority of patients. The fever is intermittent, with one or two rises to 101 to 106 F. daily. Double peaks in the daily temperature curve were observed in 50 per cent of the cases in this series. The second rise may occur late at night, and unless temperatures are taken every two or three hours during the twenty-four hours and charted graphically, this feature may be overlooked. Intercurrent infection may alter the intermittent character of the temperature and may result in periods of high sustained fever. Subjective symptoms were surprisingly few, despite the prolonged periods of chills and fever; there were an only moderate loss of strength, some loss of weight and headaches. The patients did not appear seriously ill or toxic. The tongue was not coated and did not show evidence of severe nutritional disease. A mild, general adenopathy was present in most of the patients, with cervical adenopathy in 7. The most striking physical signs were in the abdomen and were related to enlargement of the spleen, the liver or both. The spleen was enlarged in 27 patients of this series on the first examination and in 3 patients later in the disease. Seventy-three per cent showed enlargement of the liver; this was not seen without coincident enlargement of the spleen. The speed with

which the spleen enlarged was striking in many instances. In some the spleen was well down into the pelvis between the third and sixth month of the clinical course. Leukopenia develops early, the serum globulin level is elevated and the serum albumin is depressed. Anemia may be severe and frequently is accompanied by moderate thrombopenia. The anemia is mildly hypochromic or normochromic; the erythrocyte sedimentation rate is usually increased.

The diagnosis is established by the demonstration of *Leishmania donovani* in smears or cultures from material derived from spleen, bone marrow, liver, lymph node or peripheral blood. Cultures should not be discarded in less than a month, because growth in some cases may be slow. If one or more smears or cultures of the bone marrow are negative, splenic puncture should be performed. Splenic puncture was the most reliable diagnostic procedure and gave uniformly positive results. The authors warned, however, that splenic puncture should be performed only in cases in which kala-azar is suspected because of exposure in endemic areas and in which clinical data support the diagnostic impression. It should be done only when the edge of the spleen is well below the costal margin. The blood clotting time and the bleeding time should be determined beforehand. If the clotting time is significantly prolonged, whole blood should be transfused in amounts sufficient to bring it within normal limits. The site of puncture is selected midway between the edge of the spleen and the costal margin.

The differential diagnosis of kala-azar involves the exclusion of malaria, undulant fever, the various bacteremias or septicemias and primary diseases of the hematopoietic organs, such as Hodgkin's disease, aleukemic leukemia, aplastic anemia and infectious mononucleosis. Antimalarial drugs, sulfonamide compounds and penicillin are not of benefit in kala-azar except to control intercurrent infections.

Compounds of antimony are specific in the treatment of kala-azar. The drug of choice, in the experience of the authors, is ethylstibamine ("neostibosan" N.N.R.). A minimum of .5 Gm. of the drug (0.3 Gm. intravenously daily for seventeen days) should be given to patients as initial treatment or to patients who have relapsed from stibamine glucoside ("neostam" N.N.R.) or from smaller amounts of ethylstibamine. Subsequent treatment of failures or relapses should be repeated with larger amounts of ethylstibamine. Repeated failure after several adequate courses of pentavalent antimony may occur, and such cases should be treated with 4,4'-diamidinostilbene ("stilbamidine"). All patients were cured in the authors' series. Patients with kala-azar should be observed for at least six months after completion of treatment to discover relapses. These are usually associated with return of fever, enlargement of the spleen, leukopenia, anemia and elevated levels of serum globulin.

RADIOACTIVE VIRUS

A promising new method of immunologic research has been introduced by Libby and Madison¹ of the Stamford Research Laboratories, American Cyanamid Company, in their study of the topographic distribution of a radioactive virus after intravenous injection into mice. Radioactive tobacco mosaic virus (TMV) was prepared by the method developed by Born² and Stanley.³ Seedling tobacco plants 2 to 3 inches high were inoculated with tobacco mosaic virus and then placed in individual brown glass bottles, each of which contained 120 cc. of nutrient solution. To each bottle there was then added 18 mg. of sodium biphosphate (Na_2HPO_4) containing approximately 278 microcuries of radioactive phosphorus (P^{32}). The level of radioactivity was maintained for thirty days at between 1 and 3 microcuries per cubic centimeter by weekly additions of the radioactive sodium biphosphate or by complete changes in the nutrient solution. After the inoculated plants had grown for thirty days in the radioactive nutrient solution the tobacco mosaic virus was extracted from the stems and leaves by the Stanley⁴ method and recrystallized three times. The viability of the final product was proved by infecting normal tobacco plants. Evidence that the radioactivity was associated with the virus molecule was afforded by the fact that the specific radioactivity was constant during repeated crystallizations.

One hundred and five mice that weighed 18 to 20 Gm. were each injected intravenously with 0.64 mg. of the radioactive virus in 0.1 cc. solution. Twenty-four hours later a group of five test mice and five controls were etherized and bled from the heart. The pooled serum from each group was titrated for anti-tobacco mosaic virus antibodies. Tests of the distribution of the tagged tobacco mosaic virus in the various tissues was made by radioautographs. To obtain these radioautographs a 3 to 4 mm. dehydrated and paraffin-impregnated sagittal section of each mouse was placed in contact with a roentgen ray film and exposed for a period of ten to fourteen days. The resulting photographs indicated a concentration of most of the radioactive tobacco mosaic virus in the liver. Only traces were found in the other tissues of the sagittal sections.

This hepatic localization was confirmed by radioactive titrations of weighed samples of all organs and tissues. Weighed samples were dried at 125 C. for twenty-four hours and then incinerated at 600 C. for twenty-four hours. The radioactivity of each sample was then measured by means of a Geiger counter. These measurements showed that by the end of twenty-four hours 63 per cent of the injected dose of radioactive tobacco mosaic virus was located in the liver

and about 3 per cent in the spleen. About 30 per cent was distributed to the remainder of the carcass. Approximately 3 per cent was found in the urine and feces.

From the second till the tenth day after injection there was a rapid decrease in the radioactive titer of the liver, with a slower fall in hepatic titer till the end of the experiment (thirty-four days). This rapid fall in liver virus concentration was accompanied by increased elimination of radioactive elements in the urine and feces and by a rapid rise in the specific antibody titer of the blood stream. The experiments thus suggest a major role of the liver in the removal, destruction and elimination of the virus and the probable dominant role of the liver in specific antibody production.

Recognition of the liver as the presumptive dominant immunologic organ in virus disease may well prove to be a major contribution to current immunologic concepts. Work has been initiated in which other viruses will be tagged, other types of tagged proteins will be tested, and observations will be made on other animal species. Detailed histologic studies will be made by the microscopic radioautographic methods recently developed by Endicott and Yagoda⁵ of the National Institute of Health and by Evans⁶ of Columbia University.

LOCAL HEALTH UNITS FOR THE NATION

The need for local public health units to provide the six traditional preventive medical services throughout the nation has long been recognized by the members of the medical profession. The optimum size of such units and the areas to be included have been unanswered questions. Now a blueprint for the nation has been developed by the American Public Health Association.¹ Twelve hundred units, each embracing from one to six counties and at least 50,000 persons, will do the job at an estimated cost of \$1 per capita per year. A unit composed of a health officer, a sanitary engineer, public health nurses and auxiliary personnel will bring measures for control of communicable disease, sanitary supervision and advice, child and maternity welfare efforts, public health laboratory services, vital statistics service and public health education to every community, rural and urban. This report of Dr. Haven Emerson's committee has received the approval of the state health officers and many teachers of public health,² and also of sixty-five representative voluntary agencies interested in health.³

Members of the medical profession may provide leadership for this movement in various ways. On community health councils physicians may stimulate consideration of the need for a reorganized local public health administration; the establishment of local public health units based on the principles of preventive medicine and the geographic boundaries set forth in the Emerson Report;¹ the establishment of positions for local health officers which will offer a salary commensurate with the training required and the responsibility carried and which will be free of political pressure; the choice of local health officers to obtain men well trained in preventive medicine and free of political domination; expansion of schools of public health and other institutions to provide physicians, nurses, engineers, health educators, statisticians, public health laboratory directors and auxiliary technicians in sufficient numbers to meet the rapidly increasing need.

Possibly some local health officers now providing good service on a part time basis will be slow to see the need for the revolutionary shift to the full time basis. Local boards of supervisors, town councils and boards of aldermen may hesitate to pool their resources with contiguous units and thus give up some of their local autonomy. Local communities may wonder if it is really necessary to look beyond their present staff of public health workers and bring in specialists trained in public health administrative procedure. The fact that prompt realization of the complete plan may require some years is no reason for failing to begin. The medical profession must assume active leadership locally in this reformation of the local public health administration of the country.

Current Comment

PLAGUE IN THE UNITED STATES

Human plague appeared for the first time in the United States¹ in the Chinese quarter of San Francisco March 6, 1900. Between that date and Jan. 1, 1940 eight states reported cases of human plague—Washington, Oregon, California, Utah, Nevada, Texas, Louisiana and Florida. During 1946 infection had been found in ground squirrels and other rodents as far east as the Mississippi Valley. The United States Public Health Service has conducted campaigns for the eradication of infected rodents since 1908. The budget for such eradication dropped from \$200,000 in 1912 to \$51,000 by 1915. This campaign, coupled with efforts by the individual states, still continues but has languished considerably. Creel² estimated in 1941 that a well organized and well sustained campaign financed by approximately \$2,500,000 would virtually eliminate rodent plague in the United States. To date the needed

funds have not been forthcoming. This condition is a definite threat of human plague in epidemic proportions in the United States. The main conditions necessary for epidemics of human plague are infected rodents, the flea transmitter and susceptible persons in close proximity. Overcrowded housing conditions in many large cities tend toward the establishment of the conditions necessary to epidemic outbreak. Proper preventive action is needed immediately.

HISTOPLASMOSIS AND THE TUBERCULIN TEST

Much study is needed to explain the contrast in occurrence between the rare clinical cases of histoplasmosis and the numerous pulmonary infiltrates associated with histoplasmin sensitivity. Many of these lesions are easily mistaken for tuberculosis. Surveys in ninety-two major cities of the United States revealed many pulmonary lesions in persons who were non-reactors to tuberculin. In Kansas City, Mo., many of the infiltrates were in reactors to histoplasmin but not to tuberculin; a diagnosis of tuberculosis must be made on more evidence than is obtained from a roentgenogram alone.¹ Although the view was advanced that this phenomenon represented simply the reversion to negative of a once positive tuberculin test, the demonstration of a strikingly uneven geographic distribution of these cases suggested that some disease other than tuberculosis was responsible. The notion that a single agent may be responsible for the host reactions is supported in the East Central states, where tuberculin-negative persons were positive to histoplasmin, and by the recent detection of 3 nonfatal cases of histoplasmosis in Kansas City alone. This, however, is not as important as the widespread existence of pulmonary lesions caused by some agent other than the tubercle bacillus. A report from the United States Public Health Service² states that among 72 asymptomatic cases in school children in Kansas City only a few were limited to the lymph nodes, a few were of the disseminated type and approximately two thirds were nodular, sharply circumscribed foci. The remaining one-fourth were diffuse, patchy infiltrations with poorly defined borders. In some of the lesions a central core of calcification was noted originally or in later roentgenograms. The lesions tend to calcify slowly, and many infiltrations persist without complete calcification during two years of observation. Where histoplasmin sensitivity is widespread, pulmonary infiltrations as well as calcifications are frequently nontuberculous and can be differentiated from tuberculosis at present only by skin tests. The importance of performing an accurate and reliable tuberculin test when pulmonary diagnostic problems are concerned cannot be overemphasized.

ORGANIZATION SECTION

Official Notes

MEETING OF THE BOARD OF TRUSTEES

CLEVELAND, JAN. 4-7, 1948

A meeting of the Board was held Sunday, January 4, and other meetings were held during the interim session of the Association in Cleveland. All members of the Board were present.

Cooperation with Veterans Administration

The Board instructed that the Committee on Veterans' Medical Problems be requested to offer their services to the director of the Veterans Administration in the solution of problems facing the administration.

Consultants on American Health Resorts

Authorization was given to the Council on Physical Medicine to establish a group of consultants on American Health Resorts to continue with at least part of the work of the Committee on American Health Resorts, which has recently been discontinued.

Expansion of Bulletin of Woman's Auxiliary into a Magazine

The Editor was authorized to continue negotiations with a view to expanding the *Bulletin* of the Woman's Auxiliary into a monthly magazine, the subscription price of which probably will be \$1 a year.

Public Relations

The Board approved the employment of Theodore R. Sills and Company as public relations counsel and of Mr. Lawrence W. Rember as executive assistant to Dr. Lull in charge of public relations.

Increase in Expenses

A report was prepared for the House of Delegates as to the reasons for the increase in expenses and the deficit which occurred in 1947, and which promised to be even greater in 1948 unless the income of the Association was increased.

Medical Motion Pictures

It was decided by the Board that the Association cannot consider the making of motion pictures but that it can, and should, continue the policy of operating a judging and lending bureau of films.

Council on National Emergency Medical Service

Authorization was given to the Council on National Emergency Medical Service to nominate to the Board persons to serve as consultants on special problems.

On nomination from the Council, Dr. James E. Paullin was elected to serve as a consultant to the Council on matters pertaining to civilian care in time of national emergency.

The members of the Council were appointed delegates to confer with the various persons in authority and the agencies of the United States Department of the Defense, as well as with such other agencies, organizations and persons as may be involved in the work of national defense and national emergency medical service.

General Practitioner's Medal

The Board voted that no present or past officer of the Association or present member of the House of Delegates shall be eligible for the General Practitioner's Medal.

Hospital Competition with Private Practice

The report of the special committee to study the matter of hospital competition with private practice was adopted, and it was decided to incorporate it in the statement recently prepared in the headquarters office concerning the Association's Ten Point National Health Program and to distribute copies to the members of the House of Delegates on Tuesday, January 6.

Meetings of Councils of Board of Trustees

The councils of the Board of Trustees are requested not to hold meetings at the annual or interim sessions of the Association.

Appointments

Dr. Virgil P. Sydenstricker was elected to succeed Dr. John H. Musser (deceased) on the Council on Medical Education and Hospitals, and has accepted the appointment.

Dr. L. H. Bauer was appointed to represent the American Medical Association at a meeting called by the National Health Council on January 23 for the promotion of full time health units for the nation. Dr. Dean F. Smiley was appointed to serve as reporter at the meeting.

The Board's Committee to Study Nursing Problems was requested to cooperate with the conference group made up of representatives of the American Hospital Association, the American Nurses Association and the American Medical Association.

First International Poliomyelitis Conference

Official endorsement was given to the first international poliomyelitis conference of the National Foundation for Infantile Paralysis. Dr. R. L. Sensenich and Dr. E. L. Henderson were appointed to attend the conference to be held in New York July 12-17, 1948.

National Conference on Family Life

The Board added Mrs. Luther Kice to its previously appointed representatives to the National Conference on Family Life, which will be held in Washington, D. C., in May 1948.

Accident Prevention

A committee composed of Drs. Morris Fishbein, George F. Lull, Frank G. Dickinson, W. W. Bauer, R. J. Plunkett and Fritjof Arestad was appointed to confer from time to time with a similar committee of the National Safety Council on problems in accident prevention.

National Committee on Home Safety

Dr. W. W. Bauer was appointed as the liaison member of the American Medical Association to the National Committee on Home Safety, of which the Association has accepted a participating membership.

Joint Committee on Evaluation of Tuberculosis Control

The American Medical Association will cooperate with the National Tuberculosis Association, the American Public Health Association and the United States Public Health Service in planning and developing schedules for the evaluation of tuberculosis control procedures, in reviewing appraisal forms for tuberculosis work which are now available and in recommending a long range plan for appraisal of both voluntary and official agencies active in the field of tuberculosis control. A joint committee of the four organizations will be appointed for these purposes.

Cooperation with Bureau of Medicine and Surgery of the Navy Department

Authorization was given to Dr. Donald G. Anderson, secretary of the Council on Medical Education and Hospitals, to accept membership on the Board of Consultants of the Bureau of Medicine and Surgery of the Navy Department.

World Medical Association

A resolution was adopted by six members of the Board of Trustees commending the work and accomplishments of their colleagues who represented the American Medical Association as delegates and alternates at the meeting of the World Medical Association held in Paris, France, in September and assuring them of their determination to support their efforts for solidarity of world physicians and for world peace.

An appropriation was made by the Board toward the support of the World Medical Association.

Portrait of Dr. Olin West

The Board authorize the procurement of a portrait, instead of a bas-relief, of Dr. Olin West and made an appropriation to cover the expense.

Award in Recognition of Outstanding Accomplishment in the Field of Human Nutrition

An invitation from the Nutrition Foundation, Inc., to cooperate in the presentation of a yearly award in recognition of outstanding accomplishment in the field of human nutrition was accepted.

Editorial on Fee Splitting

Authorization was given by the Board for the publication in THE JOURNAL of an editorial entitled "Rebates, Kickbacks, Commissions and Medical Ethics."

Many other subjects were considered, and some of them will be again deliberated on at future meetings.

INVITATION TO SECTION ON OPHTHALMOLOGY

The Ophthalmological Society of Australia, which is a branch of the British Medical Association, has invited the Section on Ophthalmology of the Scientific Assembly of the American Medical Association to be represented at their annual meeting at Perth, Western Australia, Aug. 15 to 21, 1948. Any member of the Section on Ophthalmology who would consider going to Australia should communicate with Dr. Trygve Gundersen, Secretary of the Section, 101 Bay State Road, Boston 15.

Coming Medical Meetings

American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, April 7-9. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Philadelphia, Feb. 26. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Central Surgical Association, Chicago, Drake Hotel, Feb. 19-21. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, Feb. 23-26. Dr. Max M. Green, 1430 Tulane Ave., Room 105, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Los Angeles, Ambassador Hotel, Feb. 24-28. Dr. Carleton Mathewson Jr., Stanford Univ. Hospital, San Francisco, Secretary.

Southeastern Surgical Congress, Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S. E., Atlanta 3, Ga., Secretary.

Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.

United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

Washington Letter

(From a Special Correspondent)

Feb. 12, 1948.

Capital's Hospital Center Might Take Entire Naval Observatory Tract

Public Building Administrator W. E. Reynolds disclosed tentative plans whereby the projected hospital center in the District of Columbia would use the entire tract of the Naval Observatory, but construction of the main structure would be delayed until the observatory moves. It is now proposed to erect the hospital almost on the exact site of the observatory administration building. This would place it in about the center of the circular observatory site, which is on high ground overlooking the city. This proposal would delay start of the building until at least 1950. Previously it was planned to use only the western portion of the site. The new proposal hinges on the Navy's getting money from Congress for a new observatory site, which may be located in Virginia. A bill to provide such funds is now in the Budget Bureau. Mr. Reynolds said officials of the three hospitals which will form the new center, Garfield, Emergency and Episcopal, have agreed that it is worth while to wait for the better site. He explained that while the Naval Observatory site has been discussed it has never been finally accepted and another site is still a possibility. The House Appropriations Committee has endorsed a \$500,000 appropriation for the project for the 1949 fiscal year and has increased the cost limit of the new medical faculty from \$18,000,000 to \$19,500,000.

Assistant Federal Security Administrator

Donald Kingsley, formerly a member of the executive office staff and executive secretary of the President's Scientific Research Board, has been appointed to the post of assistant federal security administrator, succeeding Maurice Collins. Mr. Kingsley is the economic advisor of the International Labor Office in Geneva, Switzerland, and was chief of that office's mission to Greece. He was born in Cambridge, N. Y., educated in Syracuse University and the University of London, and before entering government service he taught at Syracuse University and Antioch College.

Ten Year Study of National Health

A letter from President Harry Truman to the Federal Security Agency asking that federal body to study health problems in the United States and to prepare a ten year improvement plan was made public by the White House. In the letter Mr. Truman informed Oscar R. Ewing, head of the agency, that he desired a program to complement and increase the effectiveness of health legislation that he is seeking from Congress. The Senate subcommittee on labor is considering bills providing for national health insurance.

Plans Approved for Cancer, Heart and Mental Disease Research Center

The National Capital Park and Planning Commission has given tentative approval to plans for the proposed research hospital for cancer, heart and mental diseases of the National Institute of Health, to be erected at Bethesda, Md., on Rockville Pike, opposite the Navy Medical Center. The U. S. Public Health Service and Public Buildings Administration thus will get authority to proceed with construction of what is described as the world's largest research hospital of this type. It will be thirteen stories high and will be located on a 100 acre site adjoining the present Public Health Institute. The project will cost \$30,000,000, requested by President Truman in the 1948-1949 budget, and will provide one hundred and fifty beds for patients with cancer, one hundred and fifty for those with heart disease and one hundred and fifty for mental patients. All will be subjects for research by the Public Health Service. The building will have in addition fifty bed accommodations, laboratories and other research facilities for the staff. The site was donated by the late Luke Wilson.

Pediatrician Concerned With Psychologic Factors

Dr. George S. Stevenson, medical director, National Committee for Mental Hygiene, told the National Commission on Children and Youth meeting here that the pediatrician is becoming increasingly concerned with the psychologic as well as the physiologic elements of disease. He said that in the past psychiatric education had almost completely ignored the child but that the trends toward comprehensiveness in pediatrics now include the educational field. The conference also discussed the proposed 1950 White House conference on children.

Medical Legislation

MEDICAL BILLS IN CONGRESS

U. S. Public Health Service and Osteopathy

A bill to amend the Public Health Service Act in regard to certain matters of personnel and administration, S. 1454, has passed the Senate. Before passage, the bill was amended by the adoption of an amendment submitted by Senator Smith, New Jersey, providing that graduates of colleges of osteopathy whose graduates are eligible for licensure to practice medicine or osteopathy in a majority of the states of the union, or approved by a body or bodies acceptable to the administrator of the Federal Security Agency, shall be eligible, subject to the other provisions of the Public Health Service Act, for appointment as commissioned medical officers in the Public Health Service.

G. I. Bill of Rights

Congressional action has been completed on S. 1394, increasing the subsistence benefits available to veterans pursuing full time educational courses under the G. I. Bill of Rights. This legislation will increase the benefits from \$65 per month to \$75 for single veterans, from \$90 to \$105 if the veteran has one dependent and to \$120 if the veteran has two or more dependents.

Another bill has passed the House and Senate, S. 1393, the effect of which will be to raise the ceiling of the allowance plus compensation for veterans receiving on the job training to \$250 for single men, \$325 for men with one dependent and \$350 for those with more than one dependent. The bill will be considered by a conference committee before being sent to the President.

Criminal Sexual Psychopaths

A bill introduced by Representative Miller, Nebraska, H. R. 5264, after providing penalties for designated indecent acts, proposes a new law for the District of Columbia for the commitment, detention and treatment of the criminal sexual psychopaths, defined as persons, not insane or feeble-minded, who suffer from a mental disorder coupled with criminal propensities to the commission of sex offenses.

The Physically Handicapped

Congressman Miller, Connecticut, proposes by H. J. Res. 302 to authorize annually an appropriation of \$250,000 to be expended by the Secretary of Labor to effectuate the purposes of National Employ the Physically Handicapped Week and to provide the President's Committee on National Employ the Physically Handicapped Week with adequate personnel within the Department of Labor.

STATE LEGISLATION

Kentucky

Bills Introduced.—H. 187 proposes the enactment of a hospital survey and construction act and designates the state board of health as the proper agency to apply for and receive federal funds to assist in the state construction program. The proposal also provides for the appointment of a hospital advisory council to assist and advise the state board of health in developing and administering a state plan for the construction of hospitals and in prescribing minimum standards for the maintenance and operation of any hospitals which receive or are to receive federal aid for construction pursuant to the state plan. H. 145 proposes to direct the board of trustees of the University of Kentucky to establish in connection with the university and as an integral part thereof a College of Medicine and Surgery. S. 88 proposes the creation of a Kentucky Hospital Board to advise the state board of health in matters relating to the licensing of hospitals and also proposes to establish a state hospital board to formulate minimum standards regarding the physical plant and equipment and rules and regulations necessary to administer the act. Under the proposal a hospital would mean any institution which maintains and operates organized facilities for the diagnosis, treatment and care of human beings suffering from illness, injury or deformity, where bedside nursing care is rendered for a period exceeding twenty-four hours and where the institution can care for 10 or more patients. S. 105 proposes the creation of a medical research commission to provide for a program of research in the fields of medicine, surgery and allied sciences, preventive medicine, control of diseases and all other features of medicine and surgery that affect the health and welfare of the people of the state.

Massachusetts

Bills Introduced.—H. 326 proposes the establishment at or near Boston of a major branch of the University of Massachusetts to offer courses in, among other things, medicine. H. 1602 proposes the creation of a special commission for the purpose of investigating discrimination on grounds of race, color, religion or national origin in nonsectarian educational institutions in the commonwealth.

Mississippi

Bills Introduced.—H. 98 proposes to authorize the county superintendents of education of various counties to join with the state board of health and various county health departments in providing for health education programs in the public schools. H. 228 proposes to make it unlawful for any person to drive and operate a school bus unless the operator shall have been examined by a competent physician and shall have received a certificate certifying that such person is physically and mentally competent and fit to operate such bus.

New York

Bills Introduced.—A. 157 proposes the creation of a New York state victory medical college. A. 678 proposes the creation of a board of medical technologist examiners for the purpose of examining and licensing medical technologists and clinical laboratory technicians. A. 695 and S. Res. 38 propose machinery for making a survey and study of the causes and effects of heart disease, rheumatic fever, rheumatic heart and related diseases. A. 713 proposes the creation of a state board of chiropractic examiners and defines the practice of chiropractic as the science of locating and the removing of nerve interference in the human body, according to chiropractic principles, where subluxations of the vertebral column appear or where interference or misalignment is indicated. It excludes operative surgery, the reduction of fractures, the prescription of drugs or medicines and the practice of obstetrics. A. 714 proposes that the state constitution be amended so as to deny exemption from tax liability to hospitals which discriminate against persons because of race, creed, color or national origin. A. 800 proposes the creation of a state university in the city of New York to include, among other things, a school of medicine. A. 1181 proposes the creation of a temporary state commission to make a comprehensive survey and study of the state hospitals and institutions under the jurisdiction of the departments of health and mental hygiene. S. 458, to amend the public health law, proposes the creation of a board of massage examiners and defines massage as the stroking, kneading, tapping or rolling with the hands, or with other instrumentalities, of the human body for hygienic or remedial purposes, for the purposes of relieving, alleviating or reducing affected parts thereof, but shall not include reduction of a fracture or dislocation of a bone. S. 693, to amend the education law, proposes to require each medical inspector having jurisdiction over any public school in the state to examine each pupil attending such school for symptoms of tuberculosis at least once in each school year. S. 745, to amend the domestic relations law, proposes that a child born to a married woman by means of artificial insemination with the express or implied consent of her husband shall be deemed the legitimate, natural child of both the husband and his wife for all purposes and such husband and wife and such child shall sustain toward each other the legal relation of parent and child and shall have all the rights and be subject to all the duties of that relationship including the rights of inheritance from each other.

Virginia

Bills Introduced.—H. 86 proposes regulations for the operation of the hospital construction fund which is utilized in accepting and dispensing funds to be used for the state hospital construction program. S. 77 proposes to authorize and empower the governing boards of the medical college of Virginia and of the University of Virginia to establish fifteen annual nursing scholarships each of the annual value of \$100.

GOVERNMENT SERVICES

ARMY

PROMOTE THIRTEEN GENERALS IN MEDICAL DEPARTMENT

Following recent confirmation by the Senate of promotions of thirteen general officers of the Army Medical Department, seven of those affected received either new stars or confirmation of permanent promotion at a ceremony in the Surgeon General's Office, January 27, when temporary Major General Raymond W. Bliss, Surgeon General, and temporary Major General Malcolm C. Grow, the Air Surgeon, observed their acceptance of permanent grade. Also present were five officers who received one new star: Brig. Gen. George C. Beach Jr., commanding general, Army Medical Center, Washington, D. C.; Brig. Gen. Albert W. Kenner, of the Army Personnel Board, and Brig. Gen. Thomas L. Smith, chief of the Army Dental Corps. Each received the additional star of a major general. Col. Walter D. Love, assistant chief of the Army Dental Corps, and Col. James A. McCallum, chief of the Army Veterinary Corps, received the star of a brigadier general. Others whose promotions received confirmation by the Senate were John M. Willis, commanding general, Brooke Army Medical Center, as permanent major general and, as a permanent brigadier general, Omar H. Quade, commanding general, Fitzsimons General Hospital, Denver; Edward A. Noyes, chief surgeon of the European Command; James A. Bethea, chief surgeon of the Far East Command; Guy B. Denit, surgeon of the First Army, and Joseph I. Martin, commandant of the Medical Field Service School and assistant commanding general of Brooke Army Medical Center, Fort Sam Houston, Texas.

MEETING OF HISTORIANS OF WORLD WAR II

Historians of the British Commonwealth and the United States met at the Pentagon, Washington, D. C., February 3-6 with members of the Historical Division of the Army, to report progress on the completion of the story of World War II. Great Britain was represented by Brig. Francis Latham, chief of the historical section of the Cabinet Office; Dr. J. R. M. Butler, chief civilian historian of the Cabinet Office and professor of modern history at Cambridge University, and Dr. J. C. Nerney, chief historian of the Royal Air Force. The Canadian historians in attendance were Col. C. P. Stacey, chief of the historical section of the Canadian Army; Lieut. Col. G. W. L. Nicholson, and Dr. Fred H. Hitchins, historian of the Royal Canadian Air Force. New Zealand was represented by Major Gen. Howard K. Kippenberger and Col. Monty C. Fairbrother. Australia was represented by John Balfour, who did much writing on the official Australian history of World War I. South Africa was represented by Lieut. Col. J. A. I. Agar-Hamilton, editor in chief of the Union War History.

In attendance also was the U. S. Historical Division's Civilian Advisory Committee headed by Dr. James P. Baxter, president of Williams College. The Department of the Army Historians were headed by Dr. Kent R. Greenfield, former chairman of the History Department at Johns Hopkins University.

At the conference reports of progress were given on the program of each nation in compiling the history of the military operations of World War II. The U. S. Army history of World War II will total about one hundred volumes, and at least eleven of these volumes are expected to be released during 1948, among which will be the volume on "Medical Department: Organization in Planning" and "The Training of Medical Personnel."

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel George D. Wilson

The Legion of Merit has been awarded to Lieut. Col. George D. Wilson, M. C., A. U. S., now of Asheville, N. C. The citation read as follows: For outstanding services as chief, Reconditioning Service, Oliver General Hospital, Augusta, Ga., from July 25, 1944 to Dec. 18, 1945. He devised and put into use several pieces of apparatus which were used in remedial exercises, thus materially shortening the number of hospital days, and greatly improved the condition of the patients on discharge from this hospital. He also inaugurated a method for the determination of the extent of nerve injuries which has been adopted by the medical profession. His devotion to duty, initiative and outstanding qualities of leadership contributed materially to the successful accomplishment of the mission of the Medical Department. Dr. Wilson graduated from Temple University School of Medicine, Philadelphia, in 1937 and entered military service in March 1941.

Major William L. Sharp

The Bronze Star Medal has been awarded to Major William L. Sharp, M. C., A. U. S., now of Anderson, Ind. The citation read in part as follows: For meritorious service in connection with military operations against the enemy from Nov. 9, 1944 to May 8, 1945, in Belgium and Germany. In his capacity of division neuropsychiatrist, Major Sharp discharged his duties in an exemplary manner. He was responsible for the care, treatment and disposition in the division clearing station of all battle casualties having combat exhaustion and neuropsychiatric disabilities, salvaging 44.2 per cent of all such casualties, thus avoiding a great wastage of combat strength. He also assisted his colleagues in caring for the sick and wounded. Major Sharp's professional skill, sterling character and unremitting devotion to duty reflect creditably on himself and the Medical Corps. Dr. Sharp graduated from Indiana University School of Medicine, Bloomington-Indianapolis, in 1930 and entered military service in May 1942.

Major Theodore V. Oltman

The Bronze Star Medal has been awarded to Major Theodore V. Oltman, M. C., A. U. S., now of Newton, Kan. The citation read as follows: For meritorious service performed during the period June 4, 1944 to Aug. 25, 1944. Major Oltman, then commanding a hospital unit, voluntarily served as surgeon of a surgical team in Yunnan Province, China, within enemy artillery range. He continued his duties as surgeon, operating on critical cases, without regard to the precarious military situation and to his own personal safety. Dr. Oltman graduated from Rush Medical College in 1929 and entered military service in April 1943.

Captain Wilford L. Cooper

The Army Commendation Ribbon has been awarded to Capt. Wilford L. Cooper, M. C., A. U. S., now of Lexington, Ky. The citation read in part as follows: For performance of meritorious service while chief, Septic Surgery Section, Surgical Service, and proctologist, Army Service Forces Regional Hospital, Fort Benning, Ga., from September 1944 to February 1946. Captain Cooper has discharged his duty as section chief in a wholehearted manner, with efficiency and exactness, and in addition has conducted an interward and outpatient clinic in proctology which has served the entire hospital and post. Dr. Cooper graduated from University of Texas Medical Branch, Galveston, in 1939 and entered military service in August 1944.

NAVY

NAVY AND MARINE OFFICERS BEFORE RETIREMENT BOARDS

During 1946, boards of medical survey recommended that 2,527 officers of the Navy and Marine Corps appear before retirement boards. Of those recommended 95 per cent incurred in line of duty the condition for which they were surveyed; in 2.6 per cent the condition had existed prior to entry into service but was aggravated by service; in 1.7 per cent the condition existed prior to entry but was not aggravated by service. Among the remaining 0.7 per cent the source of the condition was unknown. Diseases of the circulatory system ranked first, accounting for 23.9 per cent of the total, and diseases of the motor system were second, accounting for 11.5 per cent. The results of combat injuries were included in "miscellaneous disease," which ranked third.

With regard to age the highest percentage, 14.8 per cent, was in the age group 25 to 29 years and the next highest percentage in the age group 50 to 54 years. Other data were obtained on the disease conditions found in these officers. The highest percentage for tuberculosis was in the age group from 25 to 29 and 30 to 34 years of age, which two groups comprised 46.1 per cent of the surveys for tuberculosis. The highest percentage for diabetes mellitus occurred in the age groups from 45 to 49 and 50 to 54 years.

Arthritis was the leading cause among the medical reasons for survey of these 2,527 officers; acquired deformity was second, hypertension third and tuberculosis fourth. It is of interest that more than 45 per cent of those surveyed, which includes both Naval and Marine Corps officers, had less than six years of active duty.

MEDICAL ASPECTS OF RADIOACTIVITY

The Bureau of Medicine and Surgery of the Navy, in conjunction with the American College of Physicians, will present a course in the medical aspects of radioactivity at the Naval Medical School, Bethesda, Md., February 18-27. The course has been arranged in cooperation with the scientists and specialists from civilian occupations, the armed services and the U. S. Public Health Service. The Joint Radiological Safety Training Committee has recommended that all members of the medical departments of the armed forces be given some training in radiologic safety. It is believed that this training should be extended to include civilian medical personnel.

Medical officers, both regular and reserve of the Army and Navy, will be admitted free of charge. Officers of the medical department of the Navy on active duty may be given "authorization orders" (no expense to the United States) to attend this course. Those interested should forward a request to the Bureau of Medicine and Surgery via their commanding officer. No classes are held on Saturday. The sessions will extend from 9 a. m. to 4 p. m. daily. The speakers scheduled are outstanding men in their respective fields.

PERSONAL

Capt. Roger D. Mackey (MC), former medical officer in command, U. S. Naval Hospital, Charleston, S. C., has been ordered to the Naval Hospital, San Diego, Calif., to assume command of that station. He is relieving Capt. Frederick R. Hook (MC), who has been ordered to a protracted period of hospitalization. Captain Mackey served on the staff of the medical service of the San Diego Hospital from 1935 to 1938.

PUBLIC HEALTH SERVICE

POSITIONS OPEN FOR PSYCHIATRISTS

The U. S. Public Health Service has received information that the following state positions in community mental health work are available for psychiatrists:

- Alabama. Director of state mental hygiene program, State Department of Health, \$5,100 to \$7,100.
- Colorado. Psychiatrist, State Division of Public Health.
- Georgia. Director, Division of Mental Hygiene, Department of Public Health, \$6,600.
- Idaho. Psychiatrist, Department of Public Health, \$3,060 (half time).
- Kentucky. Director, Division of Mental Health, State Department of Health.
- Michigan. Director, Child Guidance Clinic, \$7,560 to \$8,760; fellow in child guidance, \$4,020 to \$4,740.
- Nebraska. Two psychiatrists for child guidance clinic, \$7,440 and \$6,600; clinical psychiatrist, \$4,020; two clinical psychiatrists with teaching responsibilities, \$7,500 and \$8,000.
- North Carolina. Three psychiatrists for state mental hygiene programs, \$7,500, \$6,000 and \$5,000.
- Tennessee. Director of state mental hygiene program. Department of Public Health, \$5,640 to \$8,400.
- Utah. Psychiatrist, State Department of Public Welfare, \$8,000.

For additional information write to the Mental Hygiene Division, U. S. Public Health Service, Federal Security Building, South, Washington 25, D. C.

NATIONAL ADVISORY CANCER COUNCIL

The appointment of Dr. Edward A. Doisy of St. Louis and Dr. John J. Morton Jr. of Rochester, N. Y., as members of the National Advisory Cancer Council was announced by the Public Health Service January 28. Dr. Doisy, who is a Nobel Prize winner, previously served on the council from 1940 to 1943. Dr. Morton is a former president of the American Cancer Society and is also a member of the Committee on Growth of the National Research Council. Other members of the National Advisory Cancer Council at present are: Drs. Charles Huggins, Chicago; Robert S. Stone, San Francisco; Shields Warren, Boston; Waltman Walters, Rochester, Minn.; A. C. Ivy, Chicago, and Thomas Parran, Surgeon General of the U. S. Public Health Service.

EIGHTEENTH ANNUAL VENEREAL DISEASE SEMINAR

The eighteenth annual Venereal Disease Seminar will be held in Washington, D. C., January 18. Dr. George E. Parkhurst, medical officer in charge of U. S. Public Health Service Medical Center, Hot Springs, Ark., will discuss follow-up of contacts in venereal disease case finding. Professor Erik Barnouw, director of Columbia University School of Radio, will play recordings of interviews with venereal disease contacts and will discuss radio as a case-finding tool.

Dr. Robert E. Hingson, professor of anesthesiology at the University of Tennessee, Memphis, will demonstrate a method of injecting penicillin without puncturing the skin.

SCHOOL OF NURSING IN MEXICO

Miss Lucile Petry, chief, division of nursing, U. S. Public Health Service, will spend the month of February in Mexico, D. F., studying the feasibility of establishing a school of nursing at the University of Mexico. At the request of the university's president, Miss Petry's study is under the joint auspices of the Public Health Service of the Federal Security Agency and the W. K. Kellogg Foundation. Mrs. Agnes Chagas, nursing director of the Pan American Sanitary Bureau, will be visiting Mexico during the same period.

ASSISTANCE TO BOY SCOUTS

Elbert K. Fretwell, chief executive of the Boy Scouts, recently extended formal thanks to Surgeon General Thomas Parran for assigning personnel of the U. S. Public Health Service to the staff of the Boy Scouts of America last summer when 1,150 scouts and leaders participated in a World Jamboree at Moisson, France. Gerald Ferguson served as sanitary engineer and Dr. Walter Nelson as medical director. Concerning their work, Mr. Fretwell wrote: "The effectiveness of those two men is best shown in the statement that there were no major accidents and no sickness which would not normally be expected in a group the size of ours."

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Memorial Lectures at Phoenix.—The Lois Grunow Memorial Clinic Lecture series will be held February 19 beginning at 1 p. m. and extending through February 20, at the Lois Grunow Memorial Clinic, Phoenix.

THURSDAY

William H. Bickel, Rochester, Minn., Differential Diagnosis of Foot Pain.
Elvira Goettsch, Los Angeles, Treatment of Diarrhea in Infants.
Vincent J. O'Connor, Chicago, Differential Diagnosis and Treatment of Tumors of the Kidney and Ureter in Adults.
Henry G. Williams, Phoenix, Carcinoma of the Colon and Rectum.
Francis D. Murphy, Milwaukee, Renal and Nonrenal Uremias.
Lester W. Paul, Madison, Wis., Roentgenologic Aspects of Gastrointestinal Disease.

FRIDAY

Goettsch, Certain Conditions Which Interfere with Growth.
Oscar W. Thoentz, Phoenix, Ophthalmic Plastic Procedures.
O'Connor, Conservative Surgical Treatment of Hydronephrosis.
Bickel, Backache.
John A. Eisenbeiss, Los Angeles, Intracerebral Calcification.
Murphy, Hypertensive Heart Disease and Its Management.
Frank H. Lahey, Boston, Management of Diseases of the Thyroid.
Paul, Diagnostic X-Rays.

SATURDAY

Murphy, Acute Disorders of the Heart: Their Diagnosis and Treatment.
Hugh Wilson, New Haven, Conn., Tumors of the Small Bowel.
Paul, Roentgen Examination in Chronic Joint Disease.
Goettsch, Certain Conditions Which Interfere with Growth, Section II.
Norton J. Wood, Washington, D. C., Bone and Root Resorption.
Bickel, Treatment of Complications of Fractures.
O'Connor, Modern Attitude of Treatment of Carcinoma of Prostate Gland.

ARKANSAS

Dr. Roberts Dean of Medical School.—Dr. Joseph T. Roberts, adjutant professor of medicine at Georgetown University School of Medicine and chief medical officer of the department of medicine at Gallinger Hospital, Washington, D. C., was appointed, effective Jan. 1, 1948, dean of the University of Arkansas School of Medicine, Little Rock, and head of the department of medicine. He is a graduate of Tulane University of Louisiana School of Medicine, New Orleans.

CONNECTICUT

Personal.—The Danielson Chamber of Commerce has presented its first annual Civic Achievement Award to Dr. Frank P. Todd, a practicing physician in that community since 1889.

Student Members of State Society.—The Governing Council of the Connecticut State Medical Society recently approved applications for membership of eighty-one medical students. All residents of Connecticut, they are enrolled in medical schools throughout the country, and their membership entitles them to limited participation in the society's activities. Admission of the eighty-one new members brings the total student membership in the society to one hundred ninety.

Residency Training Program in Neuropsychiatry.—A Veterans Administration Residency Training Program in Neuropsychiatry, under the Dean's Committee, Yale University School of Medicine, New Haven, will open on July 1. The program will stress training in dynamic psychiatry with emphasis on treatment and prevention, and it will offer the required training in clinical neurology. It is designed to prepare the resident for certification in psychiatry by the American Board of Neurology and Psychiatry. Training will be given at the Newington Veterans Administration Hospital, a general hospital of 352 beds with a psychiatric service of 45 beds; at the Veterans Administration Hospital, Northampton, Mass., with 1,137 beds for psychotic patients, and in the Yale Department of Psychiatry and Mental Hygiene. The inclusion of the Veterans Administration Mental Hygiene Clinic, Hartford, is under consideration.

Appointments will be made annually. Candidates may elect a one, two or three year course depending on their board requirements. All appointments are subject to approval by the Resident Review Board. Applications may be obtained from Frederick C. Redlich, M.D., Chairman, Dean's Sub-Committee in Neuropsychiatry, Yale University School of Medicine, 333 Cedar Street, New Haven, Conn.

GEORGIA

Dr. Sellers Named State Health Director.—Dr. Thomas F. Sellers, director of laboratories, State Department of Public Health, has been appointed health director of the state succeeding Dr. Thomas F. Abercrombie, resigned. Dr. Sellers is a graduate of Emory University School of Medicine, Atlanta, 1932, and was elected first secretary to the Georgia Association of Pathology in 1935.

ILLINOIS

New Mobile X-Ray Unit.—The Winnebago County Tuberculosis Association after a delay of nearly two years has purchased a bus-type chest x-ray unit to replace the trailer-type unit in use for the past four years. The mobile unit is a tuberculosis case-finding device. The bus is 28½ feet long, 8 feet wide and 9 feet 9 inches high.

Record Birth Rate.—For the second successive year the Illinois birth rate has reached a new high. Dr. Roland R. Cross, state director of public health, announced that 191,866 live births were registered in Illinois in 1947 with a corresponding rate of 23.3 births for each thousand inhabitants. Significant in the 1947 record is the gain in saving lives of young babies. The 1947 death rate of 28.4 deaths of babies under 1 year of age for every thousand births is a new record. Maternal death rate figures are as yet incomplete. The general death rate for the state is 11.2 per thousand.

Chicago

The McArthur Lecture.—Dr. Alfred Blalock, Baltimore, will deliver the Lewis Linn McArthur Lecture of the Frank Billings Foundation at the Palmer House Friday, February 27, at 8 p.m. on "Surgical Treatment of Congenital Cardiovascular Defects."

Research in Poliomyelitis.—A grant of \$25,692 has been awarded to the University of Chicago by the National Foundation for Infantile Paralysis for the study of biochemical phases of poliomyelitis. The project will be under the supervision of Earl A. Evans Jr., Ph.D., professor and chairman of the department of biochemistry.

Dr. Fred Koch Dies.—Fred C. Koch, Ph.D., Frank P. Hixon distinguished service professor emeritus of biochemistry at the University of Chicago, died January 26 at his home, aged 71, of cerebral hemorrhage. Internationally recognized for his work on hormones, enzymes and vitamins, he had been associated with Armour and Company as director of biochemical research since his retirement from the university in 1941.

Lecture on Surgery for Sanity.—Dr. Paul C. Bucy, professor of neurology and neurologic surgery, University of Illinois School of Medicine, will speak on "Surgery for Sanity" February 13 at Younkers Restaurant, following an initiation dinner of the Northwestern University chapter of Sigma Xi, national honorary science society. The program is open to members and friends of Sigma Xi. Dinner reservations may be obtained by calling University 1900, extension 415.

Cancer Refresher Courses.—The fourth Cancer Refresher Course, sponsored by the Illinois Division, American Cancer Society, Inc., in cooperation with the Illinois State Medical Society, was held January 16-23 in Chicago with forty physicians from various parts of the state attending. The programs were held in the medical schools of Northwestern University, University of Illinois, Loyola University, University of Chicago and Michael Reese Hospital. The fifth course will be held the week of March 15-19. Physicians desiring to attend should apply to the president or secretary of their county medical society.

Course on Cancer of the Oral Cavity.—A graduate course on recent advances in cancer of the oral cavity will be offered by the University of Illinois College of Dentistry, in cooperation with the Illinois division of the American Cancer Society, Inc. The course will be offered over a period of six consecutive Wednesdays from 7:30 to 9:30 p.m. beginning March 31. Dr. Bernard G. Sarnat, acting head of the department of oral and maxillofacial surgery, will be in charge of the course, which is planned to be of value to dentists, general practitioners, oral and maxillofacial surgeons and otolaryngologists. Tuition for the course has been waived through the courtesy of the Illinois division of the American Cancer Society. For information address Dr. Isaac Schour, associate dean in charge of the post-graduate school, 808 South Wood Street, Chicago 12.

Personals.—Dr. Leo M. Czaja resigned January 7 after twelve years as general superintendent of the City of Chicago Municipal Tuberculosis Sanitarium. Others who have resigned are Dr. Camillo E. Volini, superintendent of clinics, and Drs. Richard M. Davison and John J. Brosnan, who were staff

physicians.—Dr. Herman L. Kretschmer gave the Poynter Lecture at the University of Nebraska, Omaha, January 12 on "The Present Status of the Prostatic Problem." He also addressed a mixed audience of physicians and laymen in the evening on "Progress in Cancer."—Dr. Robert A. M. Esser, Chicago, has been appointed assistant director of the Behavior Clinic of the Criminal Court of Cook County.—Olaf Bergeim, Ph.D., has been promoted to the rank of professor of biological chemistry at the Chicago Professional Colleges of the University of Illinois.—Dr. Edward L. Compere, associate professor of bone and joint surgery, Northwestern University Medical School, spoke on "Fusion of the Spine After Excision of Intervertebral Disks" on February 11 before the Havana (Cuba) Medical Society. Dr. Compere plans to go to the Pacific area this summer as a special civilian consultant. He will visit army hospitals, operate, study problem cases and review the orthopedic services.

INDIANA

Emergency Service Plan.—The physicians of Greencastle are offering emergency service twenty-four hours a day through the Doctors' Exchange, which will locate the doctor on duty at that time. According to the plan, two doctors are on duty from 8 a. m. each Sunday to the following Sunday. One doctor is available at all times, and his co-worker will take calls in his absence. The service is offered to those who need a doctor and who are not able to locate the family physician.

Dermatosyphilology Foundation.—Inauguration of the Alembert Winthrop Brayton Foundation for the advancement of knowledge of dermatosyphilology was held Dec. 6, 1947 at Indianapolis General Hospital. Dr. Brayton was the first professor of the subject at the Indiana University School of Medicine. Those furthering the foundation hope to raise \$50,000 to supply added personnel and equipment for training, all of which may not be available from the city budgetary funds made available to the hospital.

Mobile Health Education Unit.—The Marion County Cancer Society has instituted a Mobile Health Education Unit which had its trial run during the five days of the Indiana State Fair in September, 1947, when it distributed 5,000 pieces of educational literature and showed six cancer movie films to 1,386 persons. The unit will cover a twelve month program of cancer education in the nine townships of Marion County this year. It will be stationed in each community in the hope that every person will accept the opportunity to have a better understanding of cancer. The unit is under the supervision of a trained health educator, Dorothy B. Howard, a graduate of the University of Michigan School of Public Health, Ann Arbor.

MARYLAND

A Demonstration Mental Hygiene Clinic.—On the campus of the University of Maryland, College Park, on January 19, a "demonstration" mental hygiene clinic was opened to serve, free of charge, residents of Prince Georges County who need psychiatric help. This is said to be the first clinic of this particular kind, made possible by the National Health Act in 1947, in the \$7,500,000 program of the U. S. Public Health Service to combat mental diseases by preventive medicine. Two similar clinics will be set up later in the middle west and on the west coast. Dr. Mabel L. Ross, psychiatrist, will head the clinic, which will also have a full time psychologist, two social workers and a public health nurse. Patients will be referred to the clinic by private physicians, courts, welfare agencies or schools. It is reported that the clinic will turn this community into a laboratory for the control and study of mental diseases from a community standpoint. The clinic is expected to help in the following work: advise local physicians when consultation with private practicing psychiatrists is not available; provide consultation service to the courts; provide outpatient treatment to persons in need of hospital care, particularly those in the early stages of mental illness; help schools in solving behavior disorders, and help social agencies to solve the emotional problems of children. The normal capacity of the clinic will be about 300 patients.

MASSACHUSETTS

Society News.—The Norfolk District Medical Society has a newly organized Woman's Auxiliary, with Mrs. Leighton F. Johnson as its first president.

Public Health Lectures.—Mount Auburn Hospital, Boston, will conclude its Public Health Lectures in the Margaret Jewett Hall with the following: February 18, Dr. David Hurwitz, Boston, "Modern Management of Diabetes"; February 25, Dr. Ward I. Gregg, Boston, "Abdominal Pain—Its Significance." These free lectures, open to the public, are given Wednesday evenings at 8:15.

Dedicate Anniversary Volume to Dr. Minot.—Following a testimonial dinner in 1945 on the sixtieth birthday of Dr. George R. Minot, Boston, his colleagues decided to prepare an anniversary volume to be published by colleagues, co-workers and former associates in honor of Dr. Minot. Invitations to contribute articles were extended to a worldwide group of workers in the field of hematology and to others who had been associated with Dr. Minot. The anniversary volume appears as the January 1948 issue of *Blood; the Journal of Hematology* and was made possible by gifts from Lederle Laboratories and Eli Lilly and Company. The committee which made the arrangements comprised William Dameshek, Boston, chairman; William B. Castle, Boston; Russell L. Haden, Cleveland; Edward B. Krumbhaar, Philadelphia; Oliver H. P. Pepper, Philadelphia; George H. Whipple, Rochester, N. Y.; L. J. Wits, Oxford, England; E. Meulengracht, Copenhagen, Denmark; R. M. Suarez, Puerto Rico, and F. H. L. Taylor, secretary, Boston. Among those whose names are signed to contributed articles are William P. Murphy, Cyrus C. Sturgis, L. S. P. Davidson of Edinburgh, Scotland, Bertel von Bonsdorff of Finland, Drs. Haden, Minot and Tom D. Spies.

MICHIGAN

Crane Lecture.—The annual A. W. Crane memorial lecture in Kalamazoo will be given February 17 by Dr. James T. Case, professor emeritus of radiology at Northwestern University Medical School, Chicago, before the Kalamazoo Academy of Medicine.

Michigan Pathological Society.—The next meeting of the Michigan Pathological Society will be at Henry Ford Hospital, Detroit, February 14. Visiting speakers are Drs. William S. Hoffman, Chicago, "Photoelectric Methods in Clinical Chemistry" and Frederick W. Sunderman, Philadelphia, "Protective Measures in Handling Radioactive Materials in Clinical Laboratories." The society at its annual meeting in December elected Dr. Arthur A. Humphrey, Battle Creek, president, Dr. Donald H. Kaump, Detroit, president-elect, and Dr. Walter A. Stryker, Wyandotte, secretary-treasurer.

Annual Postgraduate Clinical Institute.—The second annual Michigan Postgraduate Clinical Institute will be held March 10 to 12 at the Book-Cadillac Hotel, Detroit, under the sponsorship of the Michigan State Medical Society. Forty-nine outstanding clinicians will present a concentrated three day postgraduate course covering the newest developments in medicine, surgery, obstetrics, pediatrics, dermatology, ophthalmology and general practice. Two evening sessions will be held, the Wednesday night presentation being a question period and the Thursday evening program a panel discussion on "First Aid to the Acutely Injured Patient." All members of the American Medical Association and the Canadian Medical Association are cordially invited to attend. There is no registration fee.

NEW YORK

Personal.—Thorndike Saville, dean of New York University's College of Engineering since 1936, has been appointed to serve on the state's Public Health Council until Jan. 1, 1953. The council of eight members advises the commissioner of health on matters relating to the preservation and improvement of public health, including additions and amendments to the state sanitary code.

New York Tuberculosis and Health Association.—Dr. Kendall Emerson, managing director of the National Tuberculosis Association for nineteen years until his retirement on Dec. 31, 1947, was recently elected president of the New York Tuberculosis and Health Association. The association's annual health conference will be held at the Hotel Pennsylvania on March 9.

Opportunity for Psychiatric Training.—The Department of Mental Hygiene of the State of New York, State Office Building, Albany, is interested in making contact with some of the many young physicians who will be released from the armed forces within the next few months and who desire an opportunity for psychiatric training in the institutions of that department of the state.

Free Hospital Care.—Since New York State initiated its tuberculosis control program a year and a half ago, every one of its fourteen million inhabitants is assured prompt and complete hospital care and treatment free of charge. The state is offering financial aid to counties and cities for care and treatment of patients with tuberculosis, including free roentgen examination of the chest. Besides producing and distributing BCG vaccine for the prevention of tuberculosis, the state department of health has undertaken basic research on tuberculosis.

New York City

Portrait of Dr. Palmer.—A portrait of Dr. Walter W. Palmer, Bard professor of medicine at Columbia University College of Physicians and Surgeons, has been presented to the college by members of the staff, friends and fellow physicians who served under Dr. Palmer. He has been associated with Columbia for twenty-seven years and will retire this spring.

Study of Acute Cerebral Hemorrhage.—The neurologic service of Mount Sinai Hospital is asking physicians who see patients with acute cerebral hemorrhage to communicate at once with the admitting physician of the hospital, who will be glad to admit suitable patients. The hospital is interested in the study and treatment of patients with acute cerebral hemorrhage.

Cornell Medical College Alumni Day.—Cornell University Medical College celebrates its fiftieth anniversary this year, and Alumni Day will be held on March 11 at the college. The program will include registration in the morning, with luncheon at the Nurses' Residence, to be followed by the business meeting and a schedule of rounds and conferences in all departments. Dinner will be served at the Roosevelt Hotel, and dancing will conclude the day.

Long Island Medical College.—A meeting for the reestablishment of the Manhattan and Bronx Chapter of the Long Island College of Medicine was held in January. Dr. A. W. Martin Marino, Brooklyn, president of the Alumni Association, was guest speaker. The campaign for the new Long Island Medical Center was discussed. Officers elected were Dr. Benjamin Jablons, president, Dr. Elias Rauch, secretary, and Dr. Philip Kassen, treasurer.

Appoint Clinical Professor of Medicine.—Dr. David Seegal, New York, has been appointed professor of clinical medicine at the Long Island College of Medicine. Dr. Seegal, who is associated with the newly formed Maimonides Hospital in Brooklyn, formerly served with the College of Physicians and Surgeons of Columbia University as director of the research program on long term diseases at Goldwater Memorial Hospital. He is a graduate of Harvard Medical School, Boston; in 1942 he was consultant on epidemic diseases to the Secretary of War.

Cooper Union Forum Lectures.—"Whether or not the methods of science can ever be applied effectively to the control of human behavior" will be the basic inquiry of the Cooper Union Forum series, "The Sciences of Life," which began February 3 and will continue on Tuesday evenings through April 27 in the Great Hall of the Cooper Union at 8:15 p.m. Evolution, heredity, behavior, growth both physical and mental and the relationships between man and his environment will be analyzed in the light of recent scientific discoveries and atomic research by leading zoologists, psychologists, sociologists and educators. All lectures are open to the public without charge.

NORTH DAKOTA

Cerebral Palsy Demonstration Clinic.—The North Dakota Chapter of the National Society for Crippled Children and Adults in cooperation with the North Dakota Medical Association's Crippled Children's Committee and the Crippled Children's Services of the North Dakota Public Welfare held a cerebral palsy clinic in Jamestown Dec. 1-2, 1947. The demonstration and teaching clinic, devoted to conference with attending physicians and diagnosis of select cases of cerebral palsy, was conducted by Dr. Meyer A. Perlstein, Chicago. The clinic was attended by physicians, parents, nurses, therapists and social workers. To house expanding services the executive committee of the state chapter of the society has voted to enlarge the Crippled Children's School at Jamestown. A new Easter seal wing, now under construction, will enable the school to double its enrolment.

OHIO

New Department of Microbiology.—Western Reserve University School of Medicine has set up a department of microbiology with Lester O. Kramptz, Ph.D., associate professor of biochemistry in the department of biochemistry, as professor and head of the new department. Before coming to Western Reserve, Dr. Kramptz did research on the physiology of bacteria at the Rockefeller Institute for Medical Research in New York and at Iowa State College, Ames, where he obtained his degree in 1942.

Dr. Meiling Named Air Force Consultant.—Dr. Richard L. Meiling, Columbus, secretary of the Committee on National Emergency Medical Service of the American Medical Association, has been appointed expert consultant in obstetrics and gynecology by the U. S. Air Force, Major Gen. Malcolm C. Grow, the Air Surgeon, has announced. A graduate of the

University of Munich in Germany, Dr. Meiling served in Europe with the Air Force during the war as a special assistant to the Air Surgeon and was awarded the Legion of Merit, the Bronze Star and the National Defense Medal. He will be a special consultant to the Station Hospital at Lockburn Air Force Base, Columbus.

New Medical Director.—Dr. Lerleen C. Hatch, Akron, has been appointed medical director of the Goodyear Tire & Rubber Company. Dr. Hatch, who came to Akron in 1942 to direct the hospitals at Goodyear aircraft plants, has been assistant medical director of the parent company's Akron plants since November 1946. In his new position he has charge of the company's Akron hospitals and staff and will also be responsible for direction of medical policies for all Goodyear operations. A graduate of Jefferson Medical College of Philadelphia in 1930, he became chief resident physician of the University of Pennsylvania Hospital, Philadelphia. Two years later he was named chief medical officer, a position he held for ten years.

OREGON

Cancer Detection Center.—The state's first cancer detection center at Coos Bay, which opened in October, is already well booked in advance. Known as the Coos-Curry County Cancer Screening Center, it is staffed by members of the Coos-Curry Medical Society, who serve in rotation at the weekly sessions. Other organizations that play a major part in the organization and operation of the center are the Oregon State Board of Health, Oregon State Medical Society, County Health Department and Oregon State Division of the American Cancer Society, Inc.

TEXAS

Lectures on Progress in Medicine.—The postgraduate division of the University of Texas Medical Branch, Galveston, will present a program on "Advances in Medical Science with Their Clinical Interpretations and Applications" in Randall Hall in the outpatient building Feb. 23-29, beginning at 9:45 a.m. The program is being offered by the department of internal medicine and the preclinical departments. Guest speakers include Drs. John H. Lawrence, Berkeley, Calif.; George W. McCoy, New Orleans; Carl V. Moore, St. Louis, and Stuart Mudd, Philadelphia.

Public Health Award.—The Dallas Health Museum has established an annual award for the individual group making the greatest contribution to public health in Texas. The first presentation of the award, to be known as the Dallas Health Museum Award, will be made in April 1948 during the Texas State Medical Association convention in Houston. Recommendations for the award may be made by any health agency or other group, the only restriction being that the candidates' contributions must be made in Texas to advance the cause of public health in the state. Names of candidates and their achievements must be submitted to the museum by April 1 of each year.

Research on Studies of Alcoholism.—A grant of \$6,000 has been made to the Biochemical Institute of the University of Texas, Houston, by the Research Council on Problems of Alcohol for research on individual patterns of metabolism to determine the possible relationship of body processes to susceptibility to alcoholism. All types of persons will be subjects for this study. Dr. Anton J. Carlson, Chicago, president of the council, explained that this research program will fill a definite gap in studies on alcohol by determining whether there are "any unique physiological characteristics in various tissues of the body which make some individuals more prone to problem drinking than others." A prior grant of \$30,000 a year for five years was made to Cornell University Medical College-New York Hospital for similar research.

VIRGINIA

Dr. Miller Honored.—Friends of Dr. Roshier W. Miller, Richmond, presented his portrait to the Medical College of Virginia January 30. A member of the faculty of the college since 1894, when he became an instructor in the school of pharmacy, Dr. Miller is emeritus professor of materia medica and therapeutics. He has been a member of the Alumni Association of the medical college since graduation, serving for three years as president and three years as secretary and alumni trustee. Last year he was elected trustee emeritus for the Alumni Association. Dr. Miller was a member of the Richmond school board for twenty-six years and served as chairman for eighteen years. Dr. J. Morrison Hutcheson presided at the presentation of the portrait, which was presented by Dr. W. Lowndes Peple with William T. Sanger, Ph.D., president, accepting it in behalf of the college.

GENERAL

Society Elections.—Ralph I. Straus, director, R. H. Macy, Inc., has been elected president of the National Multiple Sclerosis Society, which is about to undertake a campaign to increase its membership of 7,500. The society, formerly the Association for the Advancement of Research in Multiple Sclerosis, was founded in 1946 to stimulate research, to act as a clearing house of information and to educate the public on the problems of multiple sclerosis.

Publication to Honor Osler.—The *Archives of Internal Medicine* proposes to publish in the near future a special issue devoted to celebrating the one hundredth anniversary of the birth of Sir William Osler. The editors of the *Archives* are exceedingly anxious to have informal photographs of Sir William Osler to be used in illustrating some of the material to appear in that issue. Those having such material available may send either the original photograph or a good print to Dr. Newell C. Gilbert, 535 North Dearborn Street, Chicago 10. All photographs will be returned in good condition.

Grants in Aid for Research on Sex Problems.—The Committee for Research in Problems of Sex of the National Research Council has announced that requests for grants-in-aid during the fiscal period July 1, 1948 to June 30, 1949 will be received until March 15, 1948. Application blanks may be obtained by addressing the secretary, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. Dr. George W. Corner, director of the department of embryology, Carnegie Institution of Washington, Baltimore, is chairman of the committee.

Dr. Diamond Receives Pediatric Award.—Dr. Louis K. Diamond, director of the hematology research laboratory at the Children's Hospital Medical Center, Boston, received the Mead Johnson Award for his contribution to the advancement of pediatric medicine from the American Academy of Pediatrics at ceremonies at the annual meeting in Dallas in December. Dr. Diamond's contribution was made in the treatment and study of blood disease of children and the development of the Rh blood-grouping laboratory in Boston. A graduate of Harvard Medical School, Boston, 1927, Dr. Diamond has been a member of the medical staff of Children's Hospital since 1930.

Golf Tournament at Annual Session.—The American Medical Golfing Association will hold its thirty-second tournament at Olympia Fields Country Club, Chicago, on Monday, June 21, in connection with the Annual Session of the American Medical Association. The American Medical Golfing Association will have the use of two 18 hole courses and the entire clubhouse, according to Dr. Charles E. Shannon, Chicago, chairman of the Arrangements Committee. Applications for fellowship in the American Medical Golfing Association are available by writing the secretary, Bill Burns, 2020 Olds Tower, Lansing 8, Mich.

New Tuberculosis Fellowships.—Establishment by the National Tuberculosis Association of teaching and research fellowships in tuberculosis has been announced by Dr. Esmond R. Long, director of the Division of Research. The annual stipends will range from \$2,400 to \$3,200, and provision will be made for laboratory fees and similar incidental expenses. The fellowships will be limited to graduates of American schools for teaching and investigation in the United States. Applications will be considered in the fields of pathology and bacteriology, clinical medicine, epidemiology and social and statistical research. Applicants may elect the institutions in which they wish to study. Persons interested should write to Dr. James E. Perkins, managing director, National Tuberculosis Association, 1790 Broadway, New York 19, for further information.

American Allergy Foundation.—Clyde Williams, director of Battelle Memorial Research Institute, Columbus, Ohio, has been elected president of the American Allergy Foundation, national organization for the support of scientific research and public education in allergy. Dr. Williams is also president of the American Institute of Mining and Metallurgical Engineers. The foundation is initiating a series of \$3,500 grants in aid of research projects expected to total more than \$25,000 this year. The foundation has granted \$3,500 to Wilbur A. Selle, Ph.D., professor of physiology at the University of Texas Medical Branch, Galveston, for his study, "The Role of Histamine and Other Agents in the Production of Anaphylaxis and Allergic Reactions," in which radioactive isotopes will be used for the first time in research on allergy.

First International Poliomyelitis Conference.—A preliminary announcement outlining plans for the first International Poliomyelitis Conference to be held in New York, July 12-17, has been sent to recognized professional persons,

inviting them to attend as member delegates. Invitations have been extended also through the State Department to more than sixty nations to send official delegates. In addition, some twenty other medical and scientific authorities from abroad will participate in the program. The first response from all countries that have been invited to participate in the program has been outstanding. According to Dr. Hart E. Van Riper, medical director of the National Foundation for Infantile Paralysis, many in this country and abroad declare that the problem has become so serious that poliomyelitis must be considered on an international basis with complete pooling now and in the future of all information available. Dr. Van Riper, who is general chairman of the conference, has announced the presiding officers and subjects of the plenary session as follows: Oswaldo P. Campos, Rio de Janeiro, Brazil, "The Importance of Poliomyelitis as a World Problem"; Rustin McIntosh, New York, "Poliomyelitis: The Early Stage"; Robert Kuo-Seng Lim, surgeon general, National Defense Medical Center, Shanghai, China, "The Management of Poliomyelitis: The Early Stage"; Arthur Steindler, Iowa City, "Poliomyelitis: The Convalescent Stage"; Arvid Wallgren, Stockholm, Sweden, "The Management of Poliomyelitis: The Convalescent Stage"; Carlos S. Ottolenghi, Buenos Aires, Argentina, "The Management of Poliomyelitis: The Late Stage"; James E. Paulin, Atlanta, Ga., "Bulbar Poliomyelitis"; Pierre L. LePine, Paris, France, "Immunology and Chemotherapy in Poliomyelitis"; Harry S. Mustard, New York, "The Public Health Aspects of Epidemic Poliomyelitis," and Thomas Parran, Washington, D. C., "Poliomyelitis Throughout the World." Official government delegates will present reports on poliomyelitis problems in their countries.

The plenary sessions will be preceded by the opening meeting presided over by Dr. Irvin Abell, Louisville, Ky. Delegates will be welcomed by Basil O'Connor, president of the National Foundation for Infantile Paralysis. Foreign delegates will be introduced by Dr. Morris Fishbein, Editor of THE JOURNAL. Among the other distinguished professional authorities from abroad who will participate in the program are: H. J. Seddon, Oxford, England; J. H. S. Gear, Johannesburg, South Africa; Herman Romero, Santiago, Chile, and S. van Creveld, Amsterdam, Netherlands; Fritz Buchtal, Copenhagen, Denmark; Juan Farill, Mexico, D. F., Mexico; Alfonso Montagne, Lima, Peru; Sven Gard, Stockholm, Sweden; G. Paredes, minister of public health, Republic of Panama, and Leslie N. Silverthorne, Toronto, Canada.

FOREIGN

Medical Week in Hungary.—The Hungarian Medical Trade Union is arranging to celebrate Medical Week September 4-12 as a part of jubilee celebrations of the Hungarian nation in commemoration of the one hundredth anniversary of the Hungarian War of Liberty. The Hungarian medical community cordially invites eminent medical personalities and practitioners of foreign countries to attend and participate. Further information may be obtained by writing the general secretary of the Hungarian Medical Trade Union, Budapest, V. Nádor Utca 32.

CORRECTION

Exotic Diseases.—The case of kala-azar referred to in the first sentence of the editorial in THE JOURNAL, January 10, page 111, was observed at the Army Air Force Regional Station Hospital, San Antonio, Texas, and not in New York City as was stated in the editorial.

Marriages

PEYTON RANDOLPH EVANS JR., Washington, D. C., to Mrs. Jeannette Payne Traonmilin of Wynnewood, Pa., recently.

WILLIAM F. KUHN II to Miss Erma Kathleen Mace, both of Kansas City, Mo., in Marion, Ark., Sept. 5, 1947.

JOHN DANOS LEIDHOLT, Pasadena, Calif., to Miss Priscilla Madelyn Crim of Storrs, Conn., in September 1947.

RUPERT VON TRAPP, Stowe, Vt., to Miss Henrietta Lajoie of Fall River, Mass., Sept. 17, 1947.

CARL D. MAKART, Chicago, to Miss Laurel E. Gourlay of Sydney, Australia, Dec. 27, 1947.

ROBERT B. HOENIG, New York, to Miss Janice Asheim of Forest Hills, Oct. 3, 1947.

Deaths

William Pepper * Philadelphia, for thirty-three years dean at the University of Pennsylvania School of Medicine, died at the University Hospital Dec. 3, 1947, aged 73, of coronary thrombosis. Dr. Pepper was born in Philadelphia May 14, 1874. He was graduated from the College of Arts and Sciences of the University of Pennsylvania in 1894 and from the department of medicine in 1897. After a year as resident physician at the Philadelphia General Hospital, he began the practice of medicine with his father, Dr. William Pepper. In 1899 he joined the faculty of his alma mater, serving first as assistant instructor in clinical medicine, then instructor and later assistant professor of pathology. In 1912 Dr. Pepper was appointed dean, in which capacity he served for thirty-three years, retiring in 1945 with the title of dean emeritus. He was a fellow of the College of Physicians of Philadelphia, a member of the American Association of Pathologists and Bacteriologists, American Academy of Natural Sciences, American Philosophical Society and Philadelphia Pathological Society. From 1917 to 1927 Dr. Pepper was a member of the Council on Medical Education of the American Medical Association and in 1920-1921 president of the Association of American Medical Colleges. He was a trustee and from 1929 to 1943 was president of the board, Free Library of Philadelphia, serving on many of its committees for several years. He was a trustee of the University of Pennsylvania and for many years an associate editor of the *University Bulletin*. During World War I he served as lieutenant colonel in the medical corps of the U. S. Army and as commanding officer of Base Hospital 74. He received an honorary degree of doctor of science from the University of Pennsylvania and an honorary degree of doctor of laws from Temple University. The General Alumni Society at Pennsylvania presented Dr. Pepper with an Alumni Award of Merit in 1942.

Ralph Edward McDonnell * New Haven, Conn.; born in New Haven, Jan. 26, 1894; Yale University School of Medicine, New Haven, 1920; joined the faculty of his alma mater as clinical assistant in dermatology in 1921, later clinical instructor, assistant clinical professor and associate clinical professor of dermatology; president and formerly secretary of the New Haven County Medical Society; member of the American Academy of Dermatology and Syphilology; member of the New England Dermatological Society, of which he had been secretary-treasurer; served during World War I; surgeon in the U. S. Public Health Service Reserve; affiliated with Griffin Hospital in Derby, and the Hospital of St. Raphael; attending physician in dermatology, Grace-New Haven Community Hospital University Service; died at his home in Northford Nov. 24, 1947, aged 53, of embolism.

John Nathan Simpson, Morgantown, W. Va.; born in Mason, W. Va., March 19, 1869; Johns Hopkins University School of Medicine, Baltimore, in 1902; member of the American Medical Association; fellow of the American College of Physicians; past president of the West Virginia State Medical Association, of which he had been an honorary member; honorary member and past president of the Monongalia County Medical Society; served during World War I; in 1935 retired with the title of dean emeritus from West Virginia University School of Medicine, where he had been dean of the Medical faculty since he organized it in 1902; professor of physiology at the school from 1902 to 1920 and later professor of medicine; director of the hygienic laboratory of the state department of health from 1913 to 1917; died Nov. 23, 1947, aged 78.

Ernest Brennan Bradley * Lexington, Ky.; born in Lexington May 16, 1877; University of Michigan Medical School, Ann Arbor, 1904; specialist certified by the American Board of Internal Medicine; member of the American Clinical and Climatological Association; master, past president and at one time chairman of the board of governors, American College of Physicians; past chairman, vice chairman and secretary of the medical section of the Southern Medical Association; served during World War I; formerly city bacteriologist and part time county health officer; for many years chairman of the county health department; affiliated with Good Samaritan Hospital and St. Joseph's Hospital, where he died Nov. 12, 1947, aged 70, of hypertension and cerebral hemorrhage.

Frank Alexander Sharpe, Greensboro, N. C.; born in Greensboro, Sept. 27, 1889; University of Pennsylvania School of Medicine, Philadelphia, 1916; fellow of the American College of Surgeons; member of the American Medical Association and the South Atlantic Association of Obstetricians and Gynecologists; president of the Medical Society of the State of North

Carolina; past president of the Guilford County Medical Society; for six years a member of the state board of medical examiners; served during World War I; affiliated with Wesley Long Hospital, Sternberger Hospital for Women and Children and the L. Richardson Memorial Hospital; died Dec. 21, 1947, aged 58, of coronary thrombosis.

William Joseph Pelletier * Turners Falls, Mass.; born in Shelburne, Mass., June 10, 1897; Tufts College Medical School, Boston, 1920; associate examiner of the Eastern District of Franklin County from 1935 to 1943, when he became medical examiner; past president of the Franklin District Medical Society; fellow of the American College of Surgeons; served during World War I; physician to the draft board during World War II; formerly school physician for the town of Montague and member of the board of health; affiliated with Franklin County Public Hospital in Greenfield and Farren Memorial Hospital in Montague City, where he died Nov. 16, 1947, aged 50, of hypertensive heart disease.

Francis Chappelle Goodwin, El Paso, Texas; born in La Para, Texas, Nov. 19, 1900; University of Virginia Department of Medicine, Charlottesville, 1926; member of the American Medical Association and the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; served during World War II; affiliated with the El Paso Masonic, Southwestern General, Hotel Dieu, Sisters' and El Paso City-County hospitals; chief surgeon for the Carrie Tingley Hospital for Crippled Children in Hot Springs, N. Mex.; died recently, aged 46, in an airplane crash.

Avedis Der Avedisyan, Boston; Tufts College Medical School, Boston, 1896; member of the American Medical Association; died Nov. 16, 1947, aged 75, of coronary sclerosis.

Julian Crawford Baker, Hawkins, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1897; died in the Lutheran Hospital, Eau Claire, recently, aged 73, of streptococcal infection, sclerosis of the adrenals with hemorrhage and diabetes mellitus.

Edgar Buren Baughn, Colquitt, Ga.; College of Physicians and Surgeons, Baltimore, 1904; member of the American Medical Association; served as mayor of Colquitt; died in the State Hospital at Milledgeville, recently, aged 68, of parkinsonism.

Oscar E. Bennett, Hayward, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; died recently, aged 72.

William Eli Biggs, Delight, Ark.; American Medical College, St. Louis, 1885; died in Little Rock Oct. 31, 1947, aged 85.

William Michael Boguskie, Hearne, Texas; Baylor University College of Medicine, Dallas, 1929; member of the American Medical Association; died Nov. 15, 1947, aged 47, of angina pectoris.

Henry Boss, Holland, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887; died Nov. 17, 1947, aged 84, of cerebral hemorrhage.

William Miller Brien * Orange, N. J.; University of the City of New York Medical Department, New York, 1891; Spanish-American War veteran; first mayor of West Orange; deputy physician of Essex County from 1918 to 1927, when he became assistant medical examiner of the county, resigning in 1935 to become health officer of Orange; affiliated with the Newark Eye and Ear Infirmary in Newark; died Nov. 19, 1947, aged 85, of coronary thrombosis.

Fabian Joseph Burke * St. Louis; St. Louis University School of Medicine, 1929; died in St. John's Hospital Nov. 15, 1947, aged 43, of injuries received when struck by an automobile.

George H. Caldwell * Lakewood, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; member of the Michigan State Medical Society; for many years affiliated with the Upjohn Pharmaceutical Company in Kalamazoo, Mich.; died Nov. 5, 1947, aged 73, of heart disease.

Jennie M. Callias, Pasadena, Calif.; Barnes Medical College, St. Louis, 1904; at one time practiced in Omaha, where she served on the school board and city welfare board; died Nov. 10, 1947, aged 78, of arteriosclerotic heart disease and diabetes mellitus.

William Henry Carr, Holly, Mich.; Chicago Homeopathic Medical College, 1902; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; member of the American Medical Association; died in St. Joseph Mercy Hospital, Pontiac, Nov. 16, 1947, aged 71, of cerebral arteriosclerosis.

Albert Charles Clauser, Delphi, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the American Medical Association; for many years county health officer; served during World War I; affiliated with St. Elizabeth Hospital and the Lafayette Home Hospital in Lafayette; died Nov. 12, 1947, aged 66, of cardiac thrombosis.

John Waldo Connaway, Columbia, Mo.; University of Missouri School of Medicine, Columbia, 1891; died recently, aged 87, of senility.

Lucy C. Vrooman Cooper, Hauula, Hawaii; Cooper Medical College, San Francisco, 1906; died recently.

Marshall Albert Cousens * Los Angeles; University of Illinois College of Medicine, Chicago, 1938; interned at St. Catherine's Hospital in East Chicago, Ind.; served a residency at the John D. Archbold Memorial Hospital in Thomasville, Ga., Parkway Sanitarium and the Illinois Eye and Ear Infirmary in Chicago, where he practiced; served during World War II; died Nov. 22, 1947, aged 36, of coronary thrombosis.

Albert Loyal Crane, Evansville, Ind.; Long Island College of Medicine, Brooklyn, 1928; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Medical Association and of the American Psychiatric Association; part owner and director of Clearview Hospital; consultant at the Welborn-Walker and St. Mary's hospitals; died in New York Nov. 17, 1947, aged 54.

Frank Elmer David, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; also a dentist; member of the American Medical Association; fellow of the American College of Surgeons; for many years affiliated with St. Joseph's and St. Luke's hospitals; died in Evanston (Ill.) Hospital, Dec. 5, 1947, aged 76, of cerebral hemorrhage and bronchopneumonia.

Samuel Delano, New Britain, Conn.; Harvard Medical School, Boston, 1883; died in the Hartford (Conn.) Hospital Nov. 8, 1947, aged 89, of aortic stenosis.

Charles August Dieter * Harper, Kan.; University Medical College of Kansas City, Mo., 1913; also a graduate in pharmacy; served as secretary of the Harper County Medical Society; an officer during World War I; county health officer; died in Kansas City recently, aged 63, of carcinoma of the liver.

Henry Beherald Diverty * Woodbury, N. J.; Jefferson Medical College of Philadelphia, 1887; past president of the state board of medical examiners and the Gloucester County Medical Society; for many years member of the board of health, serving as president; medical inspector of the public schools; on the staff of Underwood Hospital; died Nov. 13, 1947, aged 83, of chronic myocarditis and arteriosclerosis.

Joseph F. Dusch, Louisville, Ky.; Hospital College of Medicine, Louisville, Ky., 1903; member of the American Medical Association; also a graduate in pharmacy; for many years city physician; affiliated with SS. Mary and Elizabeth Hospital, St. Anthony's Hospital, Methodist Deaconess Hospital, Norton Memorial Infirmary, Kentucky Baptist Hospital, Jewish Hospital and St. Joseph Infirmary, where he died Nov. 14, 1947, aged 75, of coronary occlusion.

Thomas Noah Dyson, San Antonio, Texas; Baylor University College of Medicine, Dallas, 1911; member of the American Medical Association; died Nov. 12, 1947, aged 62, of coronary thrombosis and diabetes mellitus.

Bernard Heath Early * Esmont, Va.; University College of Medicine, Richmond, 1898; died in New Orleans Nov. 9, 1947, aged 70, of cerebrovascular accident and arteriosclerotic heart disease.

Martin John Echeverria * New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1889; member of the American Urological Association; affiliated with the New York Dispensary; died in St. Vincent's Hospital Nov. 5, 1947, aged 83, of coronary occlusion and hypertension.

James Edward Erwin, Lewisburg, W. Va.; Louisville (Ky.) Medical College, 1878; died in the Greenbrier Valley Hospital recently, aged 95, of senility.

Walter Leonard Ezell, Boiling Springs, S. C.; University of the South Medical Department, Sewanee, Tenn., 1903; for many years county highway commissioner and member of the local board of education; died in Mary Black Memorial Hospital, Spartanburg, Nov. 28, 1947, aged 67, of coronary sclerosis.

Dewey Foster, Westmoreland, Tenn.; Vanderbilt University School of Medicine, Nashville, 1925; member of the American Medical Association; died Nov. 11, 1947, aged 48, of myocardial failure.

George Alfred Victor Goetz * Cleveland; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1919; on the staff of the Grace Hospital; died recently, aged 55.

Andrew Joseph Lorne Guay, Vancouver, Wash.; University of Toronto Faculty of Medicine, Toronto, Canada, 1926; served during World War II; affiliated with the Veterans Administration Hospital; died suddenly recently, aged 43, of coronary thrombosis.

Pauline Handelman-Kalashnikoff * Far Rockaway, N. Y.; Kiev Medical Institute, Kiev, Russia, 1922; specialist certified by the American Board of Pathology; affiliated with the St. Joseph Hospital and the Hospital for Joint Diseases; died recently, aged 54, of coronary thrombosis and hypertension.

John Edmond Hart, Columbia, Miss.; New Orleans University Medical College, 1900; died recently, aged 77, of coronary thrombosis.

Augustus William Hengerer, Buffalo; born in Buffalo July 14, 1875; University of Buffalo School of Medicine, 1902; fellow of the American College of Surgeons; member of the American Medical Association and the Buffalo Academy of Medicine; past president of the Buffalo Surgical Society; affiliated with the Millard Fillmore and Deaconess hospitals; died Nov. 10, 1947, aged 72, of cerebral hemorrhage.

Albert Henry Horn * Steelville, Mo.; Barnes Medical College, St. Louis, 1903; past president of the Phelps-Crawford Counties Medical Society; formerly deputy health commissioner for Crawford County; died Nov. 10, 1947, aged 74, of heart disease.

Max Huhner * New York; Columbia University College of Physicians and Surgeons, New York, 1893; specialist certified by the American Board of Urology; member of the American Urological Association; formerly on the staff of Bellevue Hospital and chief of the clinic in the genitourinary department at Mount Sinai Hospital; author of many books; devised test for sterility, known as the Huhner test; died Nov. 8, 1947, aged 74, of heart disease.

James Cecil Keeley, El Paso, Texas; Eclectic Medical College of Indiana, Indianapolis, 1904; died recently, aged 77, of hypertension.

William B. Kitchen * Glasgow, Mo.; St. Louis University School of Medicine, 1907; chairman of the board of directors of the Glasgow Savings Bank; died in the Trinity Lutheran Hospital, Kansas City, Nov. 10, 1947, aged 66, of infectious hepatitis.

Ferdinand Richard Krembs * Stevens Point, Wis.; University of Illinois College of Medicine, Chicago, 1924; interned at St. Joseph's Hospital in Chicago; past president and secretary of the Portage County Medical Society; served as city health officer; first lieutenant, medical reserve corps, U. S. Army, not on active duty; affiliated with St. Michael's Hospital; died Nov. 6, 1947, aged 49, of heart disease.

Clarence Andrew Kretschmar * Detroit; University of Michigan Medical School, Ann Arbor, 1920; owner of the Kretschmar Diagnostic Clinic and Hospital, where he died recently, aged 51, of acute coronary thrombosis.

John Henry Luke * Kansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1928; past president of the Wyandotte County Medical Society; member of the Central Association of Obstetricians and Gynecologists, Kansas City Obstetrical Society and the Southwest Clinical Society; served during World Wars I and II; affiliated with the Providence Hospital, St. Margaret's Hospital and the Bethany Hospital, where he died Nov. 10, 1947, aged 47, of pneumonia.

James Carlisle McLeod * Florence, S. C.; Cornell University Medical College, New York, 1922; past president of the South Carolina Medical Association; served during World War II; in 1946 was a candidate for governor of South Carolina; surgeon in chief of the McLeod Infirmary; died Dec. 9, 1947, aged 50, of coronary thrombosis.

Mary Mabon, Oil City, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1936; member of the American Medical Association; interned at Passavant Hospital in Pittsburgh; affiliated with Polk State Hospital, where she died Nov. 14, 1947, aged 51, of carcinoma.

Edward Lowry Martindale, Clinton, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; veteran of the Spanish-American War, Mexican border war and World War I; president of the Lyons and Fulton Bridge Company; affiliated with the Jane Lamb Memorial Hospital, where he died Nov. 16, 1947, aged 78, of heart disease.

Gertrude Kirkpatrick Meck, Cleveland; Cleveland Homeopathic Medical College, 1910; died Nov. 9, 1947, aged 79.

Evelyn Dolores Mosteller Miller, Des Moines; Drake University Medical Department, Des Moines, 1896; died recently, aged 73, of carcinoma of the pancreas.

M. Jeanette Scott Miller, Allentown, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1888; died Nov. 1, 1947, aged 80, of injuries received when she fell down stairs.

George U. Grant Mills, Hackettstown, N. J.; Medico-Chirurgical College of Philadelphia, 1905; member of the board of health; affiliated with the Warren Hospital in Phillipsburg; died in the Memorial Hospital, Morristown, Nov. 17, 1947, aged 77, of uremia.

Carney Wilson Mimms, Ocala, Fla.; University of Louisville (Ky.) Medical Department, 1914; member of the American Medical Association; past president of the Marion County Medical Society; affiliated with the Munroe Memorial Hospital, where he died Nov. 5, 1947, aged 57, of coronary occlusion.

Charles James Mooney, New Rochelle, N. Y.; University of the City of New York Medical Department, New York, 1889; died in the Post-Graduate Hospital, New York, Nov. 6, 1947, aged 84, of gastrointestinal hemorrhage.

Paul Peniston, Newnan, Ga.; Atlanta Medical College, 1889; died Nov. 13, 1947, aged 80, of acute bronchial pneumonia.

Reinhard Rembe, Chicago; St. Louis Medical College, 1887; Friedrich Wilhelms Universität Medizinische Fakultät, Berlin, 1892; at one time on the faculty of the University of the Philippines College of Medicine and Surgery and on the staff of the Philippine Islands General Hospital in Manila; died in Alexian Brothers Hospital Nov. 11, 1947, aged 79.

Nathan Oyler Reynolds, Los Angeles; John A. Creighton Medical College, Omaha, 1912; member of the American Medical Association; found dead Nov. 2, 1947, aged 58.

Bruce Richardson, Beaumont, Texas; Detroit College of Medicine, 1900; affiliated with Hotel Dieu and St. Therese Hospital; died Nov. 1, 1947, aged 71, of coronary occlusion.

Samuel William Rock @ New York; University and Bellevue Hospital Medical College, New York, 1915; fellow of the American College of Surgeons; affiliated with Beth Israel Hospital, where he died recently, aged 53.

George Clifton Rodebaugh, Pasadena, Calif.; Starling-Ohio Medical College, Columbus, 1912; member of the Ohio State Medical Association and the American Medical Association; served during World War I; died in St. Luke's Hospital Nov. 6, 1947, aged 61, of coronary thrombosis.

Floyd Dwight Rodgers @ Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1910; served in France during World War I; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America and the American College of Radiology; affiliated with the Columbia and Providence hospitals; died in State Park, Nov. 7, 1947, aged 59, of tuberculosis.

Herriot C. Rooth @ Buffalo; University of Buffalo School of Medicine, 1894; formerly on the faculty of his alma mater; fellow of the American College of Surgeons; served on the staffs of the Lafayette General Hospital, of which he had been a founder, the Buffalo General Hospital and the Millard Fillmore Hospital, where he died Nov. 3, 1947, aged 80, of heart disease.

Noemi Rosenzweig, New York; Medizinische Fakultät der Universität, Wien, Austria, 1924; served on the staff of the Lincoln Hospital; died recently, aged 48.

Frank Saylor Rossiter @ Swissvale, Pa.; University of Pittsburgh School of Medicine, 1908; for many years industrial surgeon at the Westinghouse Electric Corporation and Carnegie-Illinois Steel Corporation; affiliated with St. Francis and Western Pennsylvania hospitals in Pittsburgh and the Brad-dock (Pa.) General Hospital, where he died recently, aged 61, of coronary thrombosis.

Frank Everett Sawyer @ Oakland, Calif.; Cooper Medical College, San Francisco, 1900; died Nov. 16, 1947, aged 73, of carcinoma of the stomach.

Harold William Schoon @ Sibley, Iowa; State University of Iowa College of Medicine, Iowa City, 1931; died near McCook, Minn., Nov. 9, 1947, aged 42.

D. W. Shirkey, Montgomery, W. Va.; College of Physicians and Surgeons, Baltimore, 1891; member of the American Medical Association; honorary member of the West Virginia State Medical Association and the Fayette County Medical Society; died Nov. 19, 1947, aged 78, of bronchopneumonia and hypertension.

Benjamin Ernest Sibley @ Boston; Harvard Medical School, Boston, 1905; for many years chief medical officer of the Boston Elevated and Metropolitan Transit Authority and a member of the medical staffs of Liberty Mutual Insurance Company and Massachusetts Institute of Technology; affiliated with the Brooks Hospital in Brookline, where he died Nov. 19, 1947, aged 73, of complications following a gallbladder operation.

Emery Frank Small, Vincennes, Ind.; Medical College of Indiana, Indianapolis, 1904; member of the American Medical Association; served during World War I; during World War II served as examining physician for Knox County draft board 1; formerly county coroner and member of the county and city council; affiliated with Good Samaritan Hospital; member of the board of managers of Hillcrest Tuberculosis Hospital; trustee of Vincennes University; died Nov. 21, 1947, aged 73, of angina pectoris.

Jay Dickey Smith @ Akron, Ohio; Starling Medical College, Columbus, 1906; fellow of the American College of Surgeons; affiliated with the Children's Hospital, City Hospital, St. Thomas Hospital and the People's Hospital, where he died Nov. 17, 1947, aged 68, of hypertension, arteriosclerotic heart disease and pulmonary embolism.

James Charles Sommer @ Grove City, Ohio; Starling-Ohio Medical College, Columbus, 1913; president of the county board of education; served as vice president of the First National Bank; died in Mount Carmel Hospital Nov. 21, 1947, aged 63, of cerebral hemorrhage.

Charles E. Stephens, Baldwin City, Kan.; University Medical College of Kansas City, 1892; died recently, aged 84, of cerebral hemorrhage and hypertension.

Elmer Harmon Thompson @ Burbank, Calif.; Rush Medical College, Chicago, 1903; fellow of the American College of Surgeons; formerly clinical professor of gynecology at the College of Medical Evangelists in Los Angeles; affiliated with the Burbank Hospital; died Nov. 4, 1947, aged 69, of suppurative nephritis and carcinoma.

Gilbert Frank Thompson, State Soldiers Home, Ohio; University of Cincinnati College of Medicine, 1913; affiliated with the Ohio Soldiers' and Sailors' Home Hospital; died in Lakewood (Ohio) Hospital Nov. 6, 1947, aged 71, of cerebral hemorrhage and hypertension.

Moses D. Tibbetts, Highland, Ill.; Missouri Medical College, St. Louis, 1881; director of the First National Bank; died Nov. 17, 1947, aged 90, of myocarditis.

Ervin Torok @ New York; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1899; professor of ophthalmology at the New York Polyclinic Medical School and Hospital; member of the American Ophthalmological Society; served on the staffs of Beth Israel, Beekman and Downtown hospitals in New York, Tarrytown, (N. Y.) Hospital, Grasslands Hospital in Valhalla and the Ossining (N. Y.) Hospital; co-author of "Surgery of the Eye"; died Nov. 4, 1947, aged 70, of carcinoma of the lung.

Samuel Henderson Wallace, Birmingham, Ala.; Birmingham Medical College, 1911; member of the American Medical Association; served during World War I; died Nov. 20, 1947, aged 67, of melanoma with general metastases.

Edgar Poe Walters, Pikeville, Ky.; Hospital College of Medicine, Louisville, 1907; died recently, aged 67, of coronary occlusion.

Edward Dane Warren, Holyoke, Mass.; Baltimore Medical College, 1902; served as city physician; affiliated with the Providence Hospital and the Holyoke Hospital, where he died Nov. 19, 1947, aged 70, of cerebral hemorrhage.

Frederick William Whiting, Portland, Ore.; Trinity Medical College, Toronto, Canada, 1895; died recently, aged 78, of cerebral hemorrhage.

Rollin Curtis Winslow, Battle Creek, Mich.; Northwestern University Medical School, Chicago, 1902; member of the American Medical Association; past president of the Calhoun County Medical Society; served during World War I; affiliated with the Leila Post and Community hospitals; died suddenly Nov. 21, 1947, aged 74, of coronary occlusion and diabetes mellitus.

James Louis Wood, Milan, Tenn.; University of West Tennessee College of Medicine and Surgery, Memphis, 1919; died recently, aged 74, of myocarditis.

Abraham James Zook, Burbank, Calif.; Rush Medical College, Chicago, 1897; member of the American Medical Association; affiliated with Glendale (Calif.) Sanitarium and Hospital and Burbank Hospital; died recently, aged 75, of coronary thrombosis.

LONDON

(From Our Regular Correspondent)

Jan. 15, 1948.

The Scheme for London Under the National Health Service

Though no agreement as to the National Health Service between the government and representatives of the medical profession has been reached, administrative measures are advanced. London, with its huge population living in twenty-eight boroughs in addition to the city, offers a special problem. A report to the health committee of the London County Council covers some of the new duties imposed on that body. They include the care of mothers and young children, midwifery, health visiting, home nursing, prevention of illness, care and after-care, mental health and domestic help. The cost of the service for a full year is estimated at \$8,000,000, of which half will be met by a grant from the government, the rest by a rate of 2 cents per dollar of rateable value of property. The nine education divisions of London have been adopted as health divisions, which will be further divided into one hundred and sixty-five areas, each based on a population of 20,000. They will be controlled by committees, one third of which will be elected representatives of the London County Council and two thirds of men and women with more intimate local knowledge. Each division will be in charge of a medical officer of high standing, who will be responsible under the county medical officer for coordinating the personal health services.

The plan aims at insuring the fullest cooperation between the personal health services provided by the council and the hospital, specialized services and those of the general practitioner. It is desired that the voluntary organizations now working shall continue, at any rate for a reasonable time, with the council having a small representation on their governing bodies and power to inspect their work. Health visiting will be an important part of the work, and home nursing will be encouraged. A greater degree of specialization will be encouraged in maternity and child welfare work. A recruiting campaign will be started to increase by 50 per cent the number of domestic aides in the first year.

Compulsory Treatment of Venereal Disease is Ended

In this country, unlike either fascist or communist states, there is great respect for the rights of the individual. But these, like many other things, had to be sacrificed for the more effectual waging of the war. Thus venereal diseases increased, became a greater threat to our manpower and had to be checked in every possible way. When patients came to the clinics for treatment there was at first no means of dealing with contacts who infected them. Under the Defence Regulations the treatment of venereal disease was made compulsory in those who were sources of infection. They belonged to the relatively small class unresponsive to educational and persuasive measures. At the close of 1947 the regulations ceased to operate. But they proved so useful in giving the health authorities increased opportunity for tracing contacts of patients who sought treatment at venereal disease clinics and in persuading considerable numbers voluntarily to undertake treatment that the Minister of Health has directed these authorities to do all that they can to continue this persuasion, notwithstanding the expiration of the regulation.

The procedure referred to need be considered only as an alternative to the generally adopted practice of requesting a patient under treatment to induce a contact to attend the clinic. General use should be made of a practice already operating in some clinics, that of giving the patient a slip or card bearing the patient's clinic number and the code designation of his disease,

and asking the patient to pass it on to the contact with the request, that it be presented if he later attends the clinic. Thus the case of the contact can be associated with that of the patient concerned. If a patient attending a clinic voluntarily gives the suspected source of infection, he or she should be asked for consent to the use of the information for the purpose of approaching the contact. It should be explained that the patient's identity will not be disclosed without her or his consent to this course. Information as to the contact is transmitted to a local health officer, who can then arrange for the contact to be approached by a health visitor or social worker. The contact should not be informed of the name of the patient who named her or him, unless the patient has consented to this. The health officer or clinic officer is not open to action for slander in the absence of malice. Thus the wartime compulsory treatment of venereal diseases has ceased, the health authorities have to deal with contacts only by persuasion and the boasted liberty of the Briton, even including the right to spread venereal disease, is recognized.

PARIS

(From Our Own Correspondent)

Jan. 5, 1948.

First International Congress for Clinical Biology

The Congress for Clinical Biology took place in Paris Nov. 20 to 23, 1947 on the initiative of the French Society for clinical biology, which was created in 1943 at the height of the war, without German authorization, by the National Syndicate of Laboratories for medical analysis. The minister of public health presided at the opening meeting at the Pasteur Institute lecture hall, at which were present Professors Polonowsky, Justin-Bezançon and Fleury, president and vice president of the congress. The mornings were allotted to experimental demonstrations in the hospitals and laboratories of Paris, the afternoons to reports and communications, on such subjects as cytologic diagnosis and dermatologic tests—Professor Tzanck (Saint Louis Hospital) spoke on a new method of investigation by means of aspiration with a syringe and the immediate examination of cytologic preparations; Professor Alajouanine, Drs. Thurel and Durupt, who explained the technic of gaseous encephalography by the lumbar route have obtained interesting results in cranial traumatism, infantile encephalopathies, multiple sclerosis and syphilis of the nervous system. Dr. Hermite (Sheffield) set forth the technic for biopsy with the syringe and showed photographs of paraffin sections obtained on deep neoplasms. Changes in the cerebrospinal fluid following streptomycin therapy were discussed by Tullio de Sanctis Monaldi (Rome), in 35 children with tuberculous meningitis. Mr. Desbordes, general inspector of laboratories for the ministry of public health, reported on the role of official laboratories, within the scope of the social security laws, for the detection of syphilis. The scientists visited the Percy Transfusion Center, one of the most beautiful in Europe. During the congress an International Society for Clinical Biology was created. The official journal of the French Society for Clinical Biology, *Les Annales de Biologie Clinique*, is under the management of Professor Paget.

International Congress of Psychiatry

A preparatory meeting of the first International Congress of Psychiatry took place at the Paris Faculty of Medicine under the presidency of Professor Jean Delay and the honorary presidency of Professor Lhermitte; in attendance were delegations from twenty-two nations. The management and preparation for the international congress to be held in Paris in 1950 were entrusted to a French committee consisting of: honorary presidents Pierre Janet and Jean Lhermitte; president Jean Delay; vice presidents Henri Baruk, Paul Delmas Marsalet, Georges

Heuyer and Louis Marchand; general secretary Henri Ey, and treasurer Paul Sivadon. Beside numerous committee meetings devoted to particular subjects, six meetings will be held at which various reports, each appertaining to one of the sections, will be discussed: general psychopathology (Professor E. Minkowsky, France); psychiatry clinics (Paul Guiraud); anatomico-physiopathology (Delmas Marsalet); Biologic therapeutics (Jean Dechaume); psychotherapy, psychoanalysis and psychosomatic medicine (A. Hesnard); social psychiatry (Jean Lauzier), and infantile psychiatry (Georges Heuyer).

Treatment of Acute Leukemia by Blood Transfusion

Bessis and J. Bernard, of the research laboratory of the Center for Blood Transfusion, proposed the treatment of acute leukemia by blood transfusion at one of the last meetings of the National Academy of Medicine, and Professor Laubry presented a report on spectacular results obtained in a child 6½ years of age. On admission to the hospital the child was precomatose with fever (104.2 F.) pallor, gingival lesions, hemorrhagia, hepatomegaly, splenomegaly and enlargement of the glands. Examination of the blood revealed 1,370,000 erythrocytes and 86,400 leukocytes, with 98 per cent lymphoblasts; in the medulla, 99 per cent lymphoblasts. The first transfusion of 800 Gm. of blood was given when death appeared imminent. On the following day the blood count was improved. A second transfusion was done four days later, and a third after an interval of seventeen days. The results were astonishing. The clinical symptoms disappeared and the blood count became 4,600,000 red corpuscles and 4,000 leukocytes. All transfusions were made with fresh blood, from arm to arm, without adjunction of any anticoagulant. The improvement persists, though it is too early to speak of a definite recovery. Moved by this splendid success, the authors contemplate trying this treatment in other cases of leukemia and against other diseases.

Amendments to French Laws on Autopsies

By a decree dated Oct. 20, 1947, the official regulations on autopsies were modified as follows: in hospitals and institutions on a list drawn up by the Ministry for Public Health, when the chief of the service deems that it is required in the interest of scientific or therapeutic knowledge, autopsies can be performed even without authorization of the family. The importance of this reform is enormous, especially in the field of ophthalmology, as emphasized at one of the last meetings of the National Academy of Medicine by Dr. Cavaillon, general secretary to the Ministry for Public Health, Dr. Leroux and Mrs. Sautter-Duval. Up to this date keratoplasty could only be resorted to in exceptional circumstances, although it appears from statistics that about 5,000 blind persons would be aided by the graft treatment; it is estimated that, at the Quinze-Vingts Hospital, 76 of 228 blind persons could have their vision restored.

Death of Professor Clovis Vincent

Professor Clovis Vincent, one of the most prominent surgeons of the world, has just died at the age of 69. He was a disciple of Babinski. In 1933 he became a doctor in the Paris Hospitals. During World War I he studied the phenomena of shock on the battlefields. In 1923 he published a paper on the false Bordet-Wassermann reactions and recommended caution in the diagnosis of syphilis in diseases of the nervous system. In 1928 he met Cushing in Boston and after his return to France decided to perform operations himself. One year later physician had become a surgeon after an enormous effort. This led to the presentation, before the Medical Society of the Paris Hospitals, of 8 patients with cerebral tumors cured by an operation. In 1930, with two collaborators, he presented the first clinical observation of hernia of the temporal lobe. In 1933 he obtained the official creation of a service of neurosurgery at "La

Pitié" hospital, which became one of the first neurosurgical clinics of the world. In 1936 he set forth, for the first time, his treatment in two phases of abscesses of the brain, whereby numerous patients, hitherto considered as lost, were cured. In 1939 he was appointed professor of neurosurgical clinics. "Neurosurgery is one of the most beautiful examples of what human nature is capable of in order to conquer nature" was the concluding sentence in his opening lecture in the professorship of neurosurgery, and nothing demonstrates better this affirmation than his own life. During the occupation he was one of the first "résistant" at the side of Professors Pasteur Vallery-Radot and Debre.

TURKEY

(From Our Regular Correspondent)

ANKARA, Dec. 31, 1947.

Cancer Research Institute and Cancer Control Society

The first Cancer Institute was established in 1927 by Professor Hamdi Suad of Istanbul University. Dr. Hamdi Suad was well known in Turkey and abroad for his experiments in cancer pathology. His intensive investigations into human and animal cancer enabled him to add a cancer department to the museum of the university's medical school. Because of the reorganization of Istanbul University in 1933 Professor Hamdi Suad was retired, but he continued his work at the Istanbul Charity Hospital until his death four years later. In his place Professor Oberndorfer of Germany was appointed and continued the work at the Cancer Institute until he died in 1942.

The fact that three quarters of the population are living in 40,000 villages makes it difficult to secure accurate statistics, but there is ample evidence through the steadily increasing admission of cancer patients to town and city hospitals that cancer in Turkey is on the increase, especially cancer of the lung and prostate.

In February 1947 a Cancer Institute in Ankara and a Benevolent Society for the investigation and control of cancer were established. The society is to have branches in other cities and towns. It is expected that this will throw more light on the cancer situation in Turkey. From among the fifty-seven members of the institute, professors, doctors and other scientists, there has been appointed an administrative committee of five, of which Professor Irfan Titiz is the president and Dr. Perihan Cambel, a woman pathologist, general secretary. The institute is to open laboratories and control centers, engage in research work and further the prevention and early diagnosis of cancer, enlighten the public on the subject, remove the fear and anxiety and aid those afflicted, follow up cancer patients, publish pamphlets, posters, books and reports, give radio talks concerning cancer, take steps to inform the medical and allied professions of the progress in cancer research and other matters pertaining to cancerology, and get in touch with foreign cancer institutes and cancer control societies. On payment of a yearly contribution of at least 10 Turkish pounds friends of the society are accepted as members. These contributions are to go toward a fund from which cancer-afflicted persons will receive aid, the number of hospital beds for cancer patients will be augmented and ultimately a cancer hospital will be established.

Accurate cancer death statistics are not yet available. However, it has been ascertained that the number of cancer patients admitted to hospitals during the period from 1935 to 1944 was 40,029, of which 18,968 were men and 21,061 women. According to age they ranged as follows: 3,119 aged 10 to 35 years; 6,199 aged 35 to 44; 13,012 aged 45 to 54; 11,420 aged 55 to 64, and 6,279 aged 65 and above.

According to religious belief the number was as follows: Mohammedans 35,108; Christians 3,720 and Jews 1,201. According to race, the whites numbered 39,982 and the colored 47.

MADRID

(From Our Regular Correspondent)

Dec. 31, 1947.

Fourth National Municipal Health Congress

There was an extraordinarily large attendance of health officers from all over Spain at the Municipal Health Congress in Madrid, Nov. 3-9, 1947. The minister of the interior presided at the opening and the head of the state at the closing made a long speech, which was received with obvious marks of public satisfaction. In his inaugural speech the Minister of the Interior reviewed the work done since the end of the civil war, which has indeed been great and deserves applause from the sanitary point of view.

The first report, read by Dr. Blas Sierra and Señor A. Salamanca, dealt with "Rural Housing; the Doctor's House; Health Centers." Of many communications heard in the course of the debate, one that stood out was by Dr. Vicente Cebrian, who proposed certain rules and regulations concerning this problem. The second report, which dealt with "Tuberculosis in Country Places," was presented by Drs. Laureano Lago Ferrero and Julio Barron and was discussed at length under the leadership of Dr. A. Crespo Álvarez, president of the Madrid Medical Association. "Diarrhea in Childhood: Clinical Instruction, Treatment and Prophylaxis" was the title of the third report, entrusted to Drs. C. M. Álvarez Martin and J. Santamaria Pulido. This too was the subject of a lively debate.

A meeting was held at the Madrid Faculty of Medicine, at which problems affecting the practice of visiting public health officers were threshed out and some effective resolutions were passed. Furthermore, a series of masterly lectures was given by eminent medical men, viz:

Professor Jiménez Díaz, "The Emergency Medicines of the General Practitioner"; Professor Martín Lago, "Acute Vascular Accidents"; Professor G. Marañón, "Present State of the Pathology of Growth"; Professor P. Lain Entralgo, "The Country Doctor's Reading"; Professor Clavero del Campo, director of the National Health School, "Treatment of Malaria"; Dr. J. M. López Ibor, "The Soul in the Diseases of the Body: the Pathology of Vitality," and Dr. A. Crespo Álvarez, "The Way in Which Pulmonary Tuberculosis Begins in Adults." Finally, the president of the General Council of Medical Associations, Dr. C. González Bueno, spoke on the medical and social problems of country doctors, commenting on the benefits accruing from recent legislation and that now planned, most of which is due to the persevering work of the council over which he presides.

More than 3,000 members took part in this congress, a number never before reached at any meeting in Spain. The beneficial achievements of the event were expressed in effective conclusions relating to health. These, however, have not yet been published.

National Institute of Industrial Medicine and National School of Industrial Medicine

By decree of July 7, 1944, the Ministry of Labor created the National Institute of Industrial Medicine, Hygiene and Safety. Its main fields of action are research and study on problems of industrial medicine and safety, advising the ministry and other official or private bodies, as well as the labor magistrates and law courts, on medical problems related to work. It will report on the processes of, and means of preventing, industrial accidents and diseases and will train special personnel for the care of victims of such accidents and diseases. The institute also plans to carry out physiologic studies on the problems of industrial hygiene and their maximum physiologic adaptation to the various trades, also to disseminate in every possible way all such knowledge and advice as may be useful in this connection. A series of publications are reminiscent of the rules and warnings published by similar bodies in North America.

The institute also hopes to arrange exchanges both of publications and of technical personnel with similar institutions abroad and to organize congresses and other events to deal with questions of industrial medicine, hygiene and safety. An effort in this direction has already been made at a congress recently held at Valencia. The institute will advise the Ministry of Labor on the problems inherent in the health insurance plan now functioning in Spain but with a somewhat imperfect organization.

The Institute of Industrial Medicine, Hygiene and Safety has new premises in University City (Madrid). There are five floors housing the various departments, such as consulting rooms, gymnasium, swimming pool, Industrial Safety Museum, anatomic museum, publicity office with cinema and photography plant, technical department offices, assembly hall, offices of the directorate and subdirectorate, legal adviser's department, library and administrative offices. On the second and third floors are sanatoriums with seventy-five and sixty-five beds, respectively, as well as apartments for Sisters of Charity, dining-rooms and chapel. On the fourth floor are all the research and clinical laboratories and on the fifth, terraces and accommodation for animals kept for experiments. In addition there is an annex communicating directly with the ground and first floors, in which are the operating theaters and the private patients' rooms.

To the institute is attached the National School of Industrial Medicine, whose functions will be to teach and do research. The teaching will comprise: the training of specialists in traumatology and orthopedics; the training of specialists in social insurance and social medicine campaigners; short courses in various branches of industrial medicine; prevention and safety at work, and courses and lectures in plants for the various classes of workers.

The school is to be in close contact, through its director, with the Faculties of Medicine, the Higher Research Council, the National School of Health, the National Health Insurance Fund and the School of Legal Medicine.

It is also one of the school's main ideas to encourage scientific relations with similar organizations abroad, by means of exchanges of personnel and publications and the founding of a number of scholarships.

At present the problem is being studied of developing the nutrition department on a broad basis for suitable research. The campaign against rheumatism in the working classes is to be conducted by the institute. The teaching of traumatology and orthopedics which has already begun, in the future is to be obligatory for the practice of this specialty in connection with social insurance; this teaching will form part of the curriculum of the National School of Industrial Medicine, and in this aspect it will be attached to the Spanish University as a Postgraduate School.

Among the studies already in full development may be mentioned those that aimed to prevent injury and disease in the lead and glass industries.

The director of the institute is Professor A. Lafuente Chaos, of the Valencia Faculty of Medicine, a pupil of the late Professor L. Olivares. The medical department is under the direction of Professor J. L. Rodríguez Candela, now attached to the Higher Council for Scientific Research and one of the most promising of the younger members. The physiology department is to be entrusted to Dr. F. Grande Cobian. This institute and teaching center are destined to do excellent work; both should achieve universal fame. Furthermore, a strictly scientific and nonpolitical criterion is to be applied in the selection of personnel, and for the appointment of heads of departments the old system of competitive examination is to be discarded; this is a matter for congratulation, since this system has proved nefarious in many instances, particularly in the provision of university chairs.

Correspondence

CONTRACEPTION MASKING STERILITY AND INFERTILITY

To the Editor:—In the January 3 issue of *THE JOURNAL*, page 56, Dr. S. I. Movitt of Los Angeles calls attention to two statements taken out of my paper on "Contraception Masking Sterility and Infertility" (*THE JOURNAL*, Dec. 28, 1946, p. 1047), which apparently puzzle him to the extent of incredulity.

Workers in the field of sterility are, of course, familiar with the facts as stated in my paper. To others less familiar with the results obtained by the Huhner test, there might seem to be a contradiction as implied by Dr. Movitt. The first statement to which the doctor refers is, "in an appreciable number of cases the Huhner test showed 10 spermatozoa or less per high power field despite which pregnancy has taken place." This statement is confronted with the observation that the normal range of sperm is "from 60 million to 120 million" per cubic centimeter. There is no disagreement as to this well established observation. The number of spermatozoa found by the Huhner test are as follows: in 83 women who became pregnant of the 1,000 who were studied in relation to contraception, there were 60 with data relevant to the Huhner test. Twenty per cent of these (12 cases) showed less than 10 spermatozoa per high power field in the vaginal secretion; 68.3 per cent (41 cases) had 10 or less per high power field in the cervical secretion. These are actual findings, incredible as they may appear to Dr. Movitt. Compared to these 83 women, a similar number of women who did not become pregnant showed only one and one-half to two times greater paucity of spermatozoa.

The second statement from my paper is quoted accurately by Dr. Movitt, to wit: "Absence of spermatozoa by the Huhner test, even if found on several occasions, is not always conclusive evidence of male sterility." But the quotation was amputated from the sentence which, in the original paper, immediately follows: "Normal spermatozoa may be demonstrable in the specimen of semen itself." As a matter of interest in this connection, in 5 of the 60 women who became pregnant no spermatozoa were recovered from the cervical secretion. Undoubtedly insemination at other times, not controlled by the Huhner test, must have been more adequate and successful in effecting conception. The concentration of spermatozoa in the ejaculate and their scattering within the vagina, in addition to reflux from the introitus and incomplete insemination in the first place plus diminished production encountered in sterile males, are factors which must be taken into account in comparing the numbers of sperm as found by the Huhner test and in the specimen of semen contained in the jar or condom.

I. C. RUBIN, M.D., New York.

NO RAGWEEDS IN THE BRITISH ISLES

To the Editor:—Your book notice on "Diseases of Children" edited by Paterson, appearing in *THE JOURNAL* of Dec. 13, 1947, page 1039, specifies that the authors discuss desensitization only for early hayfever and states that "nothing is said about hayfever caused by giant and dwarf ragweeds or about desensitization against this type."

Since the volume was written by British physicians and presumably for British physicians it is not surprising that this aspect of hayfever is not discussed. The ragweeds generally do not exist in the British Isles, and in fact are of no practical consequence throughout Europe. It is for this reason that the only significant hayfever in Britain is that due to the pollens of grasses, and the authors should not be censured for failing to consider the other types.

PHILIP M. GOTTLIEB, M.D., Philadelphia.

A STREPTOMYCIN HAZARD TO PUBLIC HEALTH

To the Editor:—Patients with tuberculosis are being treated with streptomycin in homes, offices and institutions throughout the country. Certain good effects suggest that this agent will find a place in the scheme of therapy. It is probably being used far oftener than truly indicated. The drug fails in some cases and leaves an infectious condition more hazardous to future contacts than existed before its use. This possible hazard is a result of the resistance which tubercle bacilli often develop to streptomycin. Perhaps two thirds of the human subjects with pulmonary tuberculosis have a resistant strain in their lesions and bronchial secretions after the drug has been used in full doses for a few months, or even a few weeks. The bacilli are resistant thereafter to further doses of any size, both in culture or animals, and even after repeated transfers.

The clinical implications can easily be seen: a patient whose disease does not become arrested and noninfectious will continue to harbor the resistant organisms, continue to spread them in his sputum and cough droplets; he may infect his family, his attendants or even casual contacts with the resistant bacilli, and they will then have an infection or disease which will not respond to streptomycin. (This is not vague theory; instances of such infection have already been diagnosed.) The same type of hazard, though less in degree, is present in other infectious discharges from the urinary, intestinal or sinus tracts.

It is not too soon to be concerned with this problem. Streptomycin has been used experimentally on human disease for about two and one half years. It has been marketed through commercial channels and sold on prescription for more than one year. The limited amount available, the high (though decreasing) cost and the imperfectly known indications for its use have restricted the number of patients to whom it has been given. Nevertheless, it has probably been administered to several thousand persons in hospitals, sanatoriums and private practice. It is not too early to take an attitude which may protect the public health.

There is no single measure which would solve the entire problem. There are a number of approaches which might be effective in part. The U. S. Public Health Service, the National Tuberculosis Association, the American Trudeau Society and the Veterans Administration have been correlating in the conduct of further research for use of the drug; they could surely arrange and adopt a plan which would "label" patients with a resistant strain of bacilli and safeguard their contacts. The various medical journals and medical societies could call the problem to the attention of readers and members. Physicians in private practice and members of sanatorium staffs could follow the work being done and use the restrictions which are recommended. Patients might be asked to guarantee a certain line of conduct before being allowed to take streptomycin. The effectiveness and value of precautions against infectious disease could be further investigated by hospital societies, public health groups and research groups. States with rules for compulsory segregation of infectious patients could add amendments which would cover the streptomycin cases. The Food and Drug Administration might be concerned with the method of prescribing such a potentially dangerous preparation. Several of these approaches are inherently weak, including those which depend on voluntary restrictions or on rulings which are already poorly enforced. Some modification of streptomycin, or some other antibiotic, may become available which will eliminate the hazard. The pharmaceutical laboratories have an added reason to find a more perfect drug. It is time for various organizations to take a quick, definite and vocal stand. The object of this letter is to draw attention to the problem and to get suitable action started. The idea has been approved by several colleagues who realize that the problem is acute, unsolved and larger than any one committee or society.

W. H. OATWAY JR., M.D.
Tucson, Ariz., and Barlow Sanatorium, Los Angeles.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL Feb. 7, page 420.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I & II*. Various centers, June 21-23. Final date for filing application is May 22. *Part II*. Various centers, April 26-27. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral*. New York, April 12-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Group B. Various centers, Feb. 16. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Oct. 18. Final date for filing application is June 1. Asst. Sec-Treas., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNCOLOGY: *Oral*. All Groups. *Part II*. Washington, D. C., May 16-22. Final date for assignment is April 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Baltimore, May 20. Chicago, Oct. 6. *Written*. Various centers, Jan. 1949. Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF PATHOLOGY: Philadelphia, March 8-10. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis, Mo.

AMERICAN BOARD OF PEDIATRICS: *Oral*. Cleveland, April 23-25. Chicago, June 25-27. Seattle, Sept. 10. Atlantic City, Nov. 17-19. *Written*. March 12, July 30. Sec., Miss Lea Leonard, 718 Royal Union Bldg., Des Moines, Ia.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. Washington, D. C., May 13-15, 1948. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral*. Chicago, June 1948. Final date for filing application is March 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

FILM REVIEW

The Development of the Gastro-Intestinal Tract. 16 mm., color, silent, 2,000 feet (two reels), showing time eighty minutes. Prepared by Joseph J. McDonald, M.D., Department of Surgery, Columbia University-Presbyterian Medical Center, New York. Procurable on purchase from: Columbia University Press, 1145 Amsterdam Ave., New York 27..

Reel I. *The Development of the Gastro-Intestinal Tract*.—The embryology of the gastrointestinal tract is shown by means of colored animated drawings beginning with the earliest stages when the primitive endoderm is first recognizable as a few cells on the deep surface of the embryonic cell mass of the free blastocyst. Its growth is traced through the period of implantation and placentation, showing in detail the early formation of the foregut, midgut and hindgut. After the age of six weeks has been reached the animated development is correlated with dissections of embryos photographed in color under magnification. Details are shown of the formation of the liver, bile ducts and pancreas, the rotation of the stomach, duodenum and intestines, the fusion of the mesenteries and the development of the omentum.

Reel II. *Anomalies*.—In this section of the film, a group of surgically important anomalies of the gastrointestinal tract have been collected. Preoperative and operative observations have been photographed and explained by means of animated diagrams as well as autopsy observations in some cases. Included in this group are examples of small bowel stenosis and atresia, duplication of the ileum, omphalocele; Meckel's diverticulum, volvulus, imperforate anus, rectovesical fistula and malrotation of the intestines.

With all its excellence, one or two things may be noted that should be avoided in future films; for example, subtitles should be complete sentences. In this film the author's eagerness to save one or two words leads to combinations like this: "amnion enclosed embryo" for "embryo enclosed in amnion" and "theory of duplication arising from" for "the theory that duplication results from." The pinching and plucking of delicate structures with forceps is especially bad when the subject is living but should not be habitual even in the dead subject. There is a great deal of this in the film, and it is especially painful to witness in the case of the extremely delicate omentum. A more careful handling of the omentum would have enabled the anatomist to demonstrate the fact that it is double and forms a bursa. Students who may some day become surgeons, and especially neurologists and ophthalmologists, should not witness such a manhandling of fragile structures.

This film is a valuable teaching aid for courses in embryology, and no instructor in developmental anatomy can afford to overlook it. It is gratifying to be able to report that the work is well done and, in many ways, definitive. The first parts would be appreciated most by freshman medical students. The concluding part would be preferred by practicing surgeons and pediatricians. Photography and animation are well done.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospital Insurance: Preexisting Cancer.—The plaintiff sued to recover the cost of hospital services rendered to the insured prior to her death. From a judgment for the plaintiff, the defendant appealed to the Court of Civil Appeals of Texas, San Antonio.

The policy sued on was issued to the deceased on Jan. 21, 1944, and it provided for the payment of hospital bills resulting from sicknesses which had their beginning not sooner than thirty days after the date of issue, i. e., not sooner than Feb. 20, 1944. The insured died from cancer on Dec. 20, 1945. The evidence showed that the insured had undergone the surgical removal of a cancerous breast in April 1943 but had been in apparent good health from that time until May 1945. The defendant insurance company contended that the insured was suffering from cancer prior to Feb. 20, 1944 and was therefore not entitled to a recovery under the terms of the policy.

The deceased's attending physician refused to state that the deceased had cancer in January of 1944. He did say that "she had the cell nests, which originated from the original cancer of the breast, but I don't think they were growing at that time, in 1944." He said that because he had seen her in May 1945 and had not even been able to detect them, and because she had died that same year with cancer all over her body, he did not believe that the "cell rests" could have spread that fast if they had been active at the date mentioned in 1944. According to the physician, the medical profession does not regard the disease of cancer as being present merely because of the existence in the body of "cell rests" or "seeds" which may become cancerous. To the question, "So that at the time this policy was taken out, actually she didn't have cancer, is that right?" he replied that "she didn't have any active cancer; if it isn't active then you don't call it cancer." When it starts to grow and you are able to identify it as that, then it is cancer. "In other words then," the examiner asked, "you don't attempt to say that she had cancer on January 14, at the time that this policy of insurance was taken out?" The physician agreed, "That is correct."

The insuring clause of the contract must be given a common sense construction, said the court. We must assume the parties intended to enter into an enforceable insurance contract. As the seeds of death are sown when the first breath of life is drawn, and flesh is subject to corruption, we cannot say that the parties intended to exclude all diseases which might develop by reason

of the presence in the insured's body of malignant bacteria, disease germs or "cell rests" which may at some later date develop into a lethal force and cause serious illness and death. We therefore conclude that the word "beginning" as used in the phrase "which (sickness) had its beginning," has reference to an illness or medically recognized disease and not merely to a condition which might in the future give rise to a disease. The court therefore concluded that, on the basis of the physician's testimony, the jury was justified in finding that the deceased did not have cancer at the time the policy was issued, and accordingly the judgment in favor of the plaintiff was affirmed.—*American Casualty & Life Co. v. Gueringer*, 205 S. W. (2d) 423 (Texas, 1947).

Miscellany

INFANT MORTALITY

The National Office of Vital Statistics, U. S. Public Health Service, Federal Security Agency, Washington, D. C., has just released a summary on infant mortality in the United States for 1945. The record of progress is impressive. From 99.9 deaths per thousand live births for the birth registration states in 1915, the infant mortality has decreased almost continuously to 38.3 in 1945. However, the reduction was not shared equally by each of the age groups. The rates of decline vary inversely with age. The largest decreases occurred for infants over 1 month of age, the rate for the 6 to 11 months age group having dropped 80 per cent and that for the 1 to 5 months age group 71 per cent since 1915. The corresponding relative decreases for the age groups under 1 month and under 1 day were 45 per cent and 25 per cent, respectively. These differences in the rate of decrease for each age group have been accompanied by an increase in the importance which mortality during the earliest days of life bears to total infant mortality. Neonatal mortality (i. e., mortality under 1 month of age) constituted a decidedly greater proportion of total infant deaths in 1945 than in 1915. This increase, however, was not general throughout the first month of life but was confined to the early neonatal period. In 1915, 30.1 per cent of all infant deaths occurred under 1 week of age; by 1945 this proportion had increased to 51.6 per cent. On the other hand, the proportion of infant deaths occurring during the second, third and fourth weeks of life and in each of the succeeding months decreased during these years.

The variation in mortality by age is striking, the probability of survival through infancy increasing sharply as the older ages are attained. Mortality during the first day of life is extremely high in comparison with each of the other age groups. After 1 day and under 1 month of age the infant mortality rates decrease rapidly but remain at a relatively high level, and the mortality rate of 24.3 per thousand for the entire neonatal period contrasts sharply with the second largest monthly rate of 2.8 for the second month of life. In comparison of the neonatal mortality rate with that for the 1 to 11 months group, it appears that more infant deaths occur during this period than during the remainder of infant life.

The greater ability of female infants to survive as compared with male infants was observed. The 1945 infant mortality rate for all males under 1 year of age was 42.7 and for females was 33.6. A similar sex differential appears in each age group but is greatest at the youngest ages and tends to decrease with increasing age, the mortality rate for male infants exceeding that for female infants by 32 per cent during the first month of life, by 22 per cent during 1 to 5 months, and by 15 per cent during 6 to 11 months.

Infant mortality is much higher among Negro infants than among white infants and is still higher among other nonwhite than among Negro infants. The rates in 1945 for these racial groups (white, Negro, other nonwhite) were 35.6, 56.2 and 74.3, respectively. These differences are due chiefly to the relatively greater mortality among nonwhite infants at the older ages; the racial differences in neonatal mortality, although substantial, are small compared with mortality during the remainder of infant

life. The neonatal mortality rate for Negroes exceeds the neonatal mortality rate for whites by 38 per cent, and the corresponding rate for nonwhite infants other than Negro is 21 per cent greater than the rate for whites. Between 1 and 11 months of age, however, the mortality rate for Negro infants is twice that for white infants and the rate for other nonwhite infants is over three and a half times greater than that for white infants.

Deaths from communicable disease are relatively frequent throughout the first year, whereas deaths from causes associated with prenatal conditions and with birth trauma usually occur during early infancy. For mortality from the pneumonias and influenza and from diarrhea, enteritis and ulceration of the intestines, the first month of life is the most hazardous. The preponderant number of deaths from premature birth, congenital malformation and injury at birth occur during the neonatal period, and more than half the deaths from premature birth and from injury at birth occur during the first day of life.

From 1920 to 1945 the decrease which occurred in total infant mortality was due chiefly to progress in the control of the major communicable causes of death. The infant mortality rate for pneumonia and influenza dropped 62 per cent from 13.8 in 1920 to 5.3 in 1945; and infant mortality from diarrhea, enteritis and ulceration of the intestines declined from 14.9 to 3.0, or 80 per cent. Large proportionate decreases also occurred for whooping cough, syphilis, tuberculosis, convulsions, measles, diphtheria and scarlet fever.

The mortality rates for the nonwhite races greatly exceed those for white infants for most of the causes which usually result in death during postneonatal infancy. The pneumonia and influenza mortality rate was 4.5 among white infants and 10.9 among Negro infants. Among nonwhite infants other than Negro this group of diseases caused 16.6 deaths per thousand births and was the leading cause of death. The mortality rate for diarrhea, enteritis and ulceration of the intestines for white infants was 2.7 as compared with 4.7 for Negro infants and 10.8 for other nonwhites. Other causes which had strikingly higher rates among the nonwhite than among the white races were whooping cough, tuberculosis, syphilis, diseases of the respiratory system (other than pneumonia and influenza) and accidental causes.

Only small racial differences appear in the relative frequency of deaths from causes peculiar to early infancy. Mortality from premature birth was lowest for nonwhite infants other than Negro, and the mortality rates for congenital malformations and for injury at birth were greater in the white than in either of the nonwhite groups.

To compare again infant mortality conditions in 1915 and 1945, improved conditions of public health and advances in medical knowledge with regard to the problem of infant disease and death have resulted in a tremendous reduction in mortality during later infancy but have exerted a much smaller influence on mortality resulting during earliest infancy from congenital conditions and difficult birth. Although much room for improvement still remains, further progress in the reduction of total infant mortality will depend increasingly on improvement of the prenatal and early extrauterine environment.

In considering these data, qualification must be made for under-registration of births and of infant deaths. Death registration is probably least complete among infants surviving less than one day. This is due, in part, to the possibility of such deaths being reported as stillbirths. Mortality rates are probably understated for earliest infancy, while those for older infants are somewhat overstated.

In comparing annual infant mortality rates consideration must be given to the effect of changing annual numbers of births. Since the group of infants who die during a given year is comprised of infants born during both the given and the preceding years, the annual number of births does not constitute the true infant population exposed to the risk of dying; and changes in the annual number of births introduce a measure of bias into the conventionally computed infant mortality rate. The infant mortality rate for 1945, adjusted for the decrease in the number of births from 1944 to 1945, is 38.2 per thousand.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Electrolyte Changes in Diabetic Acidosis.—The study reported by Martin and Wertman was undertaken to see if in diabetic acidosis there was any correlation between p_{H} , calcium, potassium and magnesium levels and the electrocardiographic changes. Patients who entered the hospital in severe diabetic acidosis were followed for several days with synchronous determinations of blood chemistry and electrocardiograms. Sagging of the ST segments was a prominent feature of the electrocardiogram on entry when acidosis was severe. This change usually disappeared within twenty-four hours. In 16 of 19 instances of depressed ST segment, the p_{H} or carbon dioxide combining power was low. However, in about a third of the patients whose records showed isoelectric ST segments the p_{H} or carbon dioxide combining power was low. Experimentally, depression of the ST segment occurs with moderate elevation of the serum potassium; but there was no correlation with changes in serum potassium levels. Thirty-seven records showed prolonged QT intervals, many of these occurring one to four days after intensive therapy had been instituted. Sixteen of these were associated with low total or ionized serum calcium or potassium. Twenty-one of the records which showed prolonged QT intervals were associated with normal levels of serum calcium and potassium. There were 7 patients in whom the QT interval was greatly prolonged; in 6 of these the serum calcium or potassium levels were below normal. These observations suggest that in some cases factors other than serum calcium and potassium depletion may be responsible for the prolongation of the QT interval. There was a high degree of correlation between low T waves and low serum potassium levels. The T waves increased in amplitude with return of the potassium to normal or elevated levels. The relation of low serum magnesium to the electrocardiographic changes needs additional study. The factors present in diabetes mellitus which may affect the myocardium are complex and include the relation between extracellular and intracellular electrolytes, cardiac nutrition in acidosis and ketosis and the effects of anoxia and azotemia.

Potassium Thiocyanate in Essential Hypertension.—Ruskin and McKinley administered six drugs, unknown to the patients, in various rotations to 68 patients with uncomplicated essential hypertension. Periods of therapy were interspersed with rest or control intervals of two to four weeks. Potassium thiocyanate was started at 0.2 Gm. three times a day. Serum potassium thiocyanate concentration was determined by a method adapted to the Evelyn colorimeter. Maintenance dosages of potassium thiocyanate necessary to maintain therapeutic blood levels varied from 0.2 to 1.2 Gm. daily, and the drug was continued for three months. Blood pressures were recorded twice weekly between 9 and 10 a. m., in the same arm, by the same observer. The best symptomatic relief was obtained from the administration of a placebo or nicotinic acid. "Glucophylline" (a methyl xanthine derivative), phenobarbital and mannitol hexanitrate decreased the complaints of fewer patients and increased the symptoms in more cases than the placebo or nicotinic acid. Potassium thiocyanate, on the other hand, maintained or increased patients' complaints in almost one half of the cases and decreased them in less than one third. Increase of symptoms undoubtedly occurred more frequently at serum thiocyanate levels above 15 mg. per hundred cubic centimeters but was also frequent and, at times, perilous at the more commonly accepted "therapeutic" levels. Thus the administration of potassium thiocyanate seems to be unreliable and hazardous. The authors conclude that the efficacy of drugs and other methods in the treatment of hypertension must be viewed with skepticism, particularly in the absence of control observations.

Infarction of Lung in Children.—According to Zuschlag pulmonary infarctions occur more frequently in children than is generally believed. At least 74 cases are described in the literature, and data on an additional 38 cases are reported in this paper. The etiologic factors in thrombosis are endothelial injury, slowing of the blood flow and changes in the blood. Infection, atelectasis, allergy and venoclysis may be contributory factors. It is usually impossible to distinguish between embolic and thrombotic infarcts. Detailed gross dissections and a large series of microscopic sections are needed in order to make an accurate differentiation. It is believed that emboli more often than primary thrombi are responsible for pulmonary infarctions in children and that the emboli originate in the iliac and femoral veins more often than in other peripheral veins. The fact that the formation of thrombi in a patent ductus arteriosus may be the source of fatal pulmonary embolism constitutes an additional reason for the early ligation of a patent ductus arteriosus. Roentgenograms of the chest in cases with clinical signs suggesting pulmonary infarction may be helpful in establishing the diagnosis. In the majority of cases pulmonary infarction among children is associated with severe infections. The mechanism of death due to occlusion of the pulmonary circulation is still in controversy. The general opinion is that the mechanical factor is the initial one, followed by reflex pulmonary atelectasis, bronchial spasm and reflex spasm of several or all of the pulmonary arteries. Sudden death from pulmonary embolism occurs more rarely in children than in adults. The clinical diagnosis of pulmonary infarction is seldom made in children because coexisting disease may mask the symptoms and signs.

Vitamin B Complex in the Newborn.—Hamil and his associates determined the concentrations of thiamine, riboflavin, nicotinic acid, N¹-methylnicotinamide, calcium pantothenate and biotin in urine from 24 healthy male infants during their first week of life. The maximal average concentrations of thiamine and of pantothenic acid were found in the urine excreted on the third day of life; the maximal average value for riboflavin was found on the first day; and the maximal average concentrations of nicotinic acid, N¹-methylnicotinamide and biotin on the second day. By the seventh day the average concentrations had declined. Thus estimation of the daily excretion of the vitamins indicated that secretion into the urine was high during the first three days, when the loss of weight was rapid and the intake of vitamins small. As the supply of breast milk increased, excretion of vitamins in the urine continued to decrease. The large amounts excreted early in life apparently represent tissue storage during intrauterine development and reduction of the stores in response to changes resulting from the transition to the extrauterine environment.

Penicillin for Empyema.—Prince and Temple present the histories of 9 children with empyema who were treated with varying amounts of penicillin. The ages of the patients ranged from 5 weeks to 5 years. Three patients required surgical drainage after unsuccessful penicillin therapy. Six patients responded well to penicillin, and surgical intervention was not necessary. *Staphylococcus aureus* was the causative agent of the empyema in 4 patients and the pneumococcus in 2 patients. No organisms could be cultured from the empyema fluid of 2 patients. In 1 patient *Hemophilus influenzae* was observed after surgical drainage, but this organism was not believed to have been the etiologic agent. That small doses may be adequate for infants is illustrated in case 4, in which the patient received penicillin alone in amounts of 2,500 units intramuscularly every three hours and two intrapleural injections of 10,000 units each. This patient recovered without surgical drainage. The last 4 patients received 15,000 or 20,000 units of penicillin intramuscularly every three hours and frequent intrapleural injections of 30,000 to 50,000 units in 10 cc. of isotonic solution of sodium chloride. All patients who responded to medical treatment did so within one week after penicillin was started. The 3 patients who did not respond without surgical drainage had complications which may have prevented successful penicillin therapy. Two had pneumothorax with bronchial fistula. The lung could not be reexpanded by aspiration. One of these patients had large bands and clots of fibrin, which could not be removed through a needle. The third patient also had fibrin clots, and the purulent fluid was too thick to aspirate. The authors conclude that the results in children are similar to those obtained in adults.

Drug Allergy.—According to Sherman allergy to drugs is common and its manifestations vary in importance from transitory cutaneous eruptions to fatal reactions. The symptoms which are considered due to sensitization include not only the

usual allergic symptoms of asthma, rhinitis, urticaria and angioedema but drug fever, leukocytosis, arthralgia, lymphadenopathy and many types of cutaneous eruptions. There is also considerable evidence that hepatitis, agranulocytosis and thrombocytopenia due to drugs are phenomena of sensitization rather than of primary toxicity. In sensitization due to protein drugs, circulating antibodies are usually demonstrable and skin tests are of value in diagnosis. In cases due to the nonprotein drugs, antibodies are rarely demonstrated by the usual methods and skin tests, except for patch tests in certain types of dermatitis, are of little diagnostic value. Microscopic studies have demonstrated widespread visceral lesions, chiefly arteritis and focal necrosis, in patients with clinical evidences of drug sensitization. The diagnosis of drug allergy depends primarily on a knowledge of its diverse manifestations.

Veratrum Veride and Magnesium Sulfate in Eclampsia.

—Irving outlines the routine treatment of eclampsia in use at the Boston Lying-In Hospital and reviews the results obtained with this method in 32 cases. He analyzes some collected statistics on the results obtained with magnesium sulfate alone and on those attending the use of veratrine with or without magnesium sulfate. Although the results in both series are good, the advantage appears to be with the veratrine group. For a number of years the main reliance at Boston Lying-In Hospital was on magnesium sulfate alone given intravenously after the technic of Lazard. The results have been so much more satisfactory since Bryant's introduction of veratrine that its use will probably be continued.

Maternal Rh Sensitization and Normal Child.—Carter reports 4 cases of maternal sensitization to the Rh factor in which clinical manifestations of congenital hemolytic disease failed to develop in the children. It is suggested that this may not be an unusual phenomenon. The author points out that since both blocking antibodies and regular agglutinins are involved in this series, the failure of clinical hemolytic disease to develop in the children cannot be ascribed to the lack of one or another type of antibody. The choice would seem to lie between the theory of inaccessibility of maternal agglutinins to the baby's red cells, and the postulate that the child is relatively immune to the maternal antibody. The first alternative is favored by Dockeray and Sachs, who suggest that antibodies pass the placental barrier only under certain conditions. However, in 3 of the 4 cases antibodies to Rh were demonstrable in the blood of the child. It is possible that individual infants may vary in their ability to withstand the hemolytic or agglutinative effects of the maternal antibodies.

Fate of Endocardial Vegetations Following Penicillin.

—Geiger and Durlacher say that a number of clinics, including their own, have reported cases of both acute and subacute bacterial endocarditis in which penicillin treatment was followed by the disappearance of all symptoms and sterilization of the blood for periods now reaching three and one-half years. Such enduring remissions in a disease that usually runs its course to death within one year speak convincingly of cure. The argument that these lesions may not be healed and may merely represent examples of the rare or hypothetical "bacteria-free" stage of the disease is refuted by the considerable number of clinically cured patients. Complete and ultimate proof of cure rests on the demonstration of healed and sterile remnants of vegetations in previously treated patients following death from other causes. Four such cases are reported in this paper. The healing process evidently results in the disappearance of bacteria from the lesions, not merely their incarceration within the vegetations.

Cooking Procedures and Staphylococcus Food Poisoning.

—Hussemann and Tanner state that the increasing number of confirmed cases of food poisoning resulting from contamination with staphylococcus indicate the need for investigations on the practical aspects of this problem. They report an attempt to establish thermal death time-temperature relationships for one strain of staphylococcus in cream filling. In the method used for mixing and cooking cream filling, the mixture was not boiled. This method is in harmony with the principles for proper starch and egg cookery. The thermal death time-temperature relationships determined here may perhaps be applicable to the feasibility of rebaking cream-filled mixtures as a prophylactic measure. When the temperatures attained in the rebaking procedures developed by Stritar, Dack and Jungewaelter were compared with critical thermal death times and temperatures, it appeared that their method allowed for reaching or exceeding the minimum requirements for destruction of staphylococci,

when the cream puffs were maintained in an oven of 190.6 C. for thirty minutes. Apparently there is some merit in the rebaking procedures, but bakers must be cautioned to control the conditions under which the work is done, or a false sense of security may result.

Cerebral Angiography.—Hodes and his co-workers report experiences with cerebral angiography in 100 patients. In most of the patients the technic employed was that of percutaneous injections of the carotid artery. Thorium dioxide ("thorotrast," 10 to 12 cc. for each injection in adults and 8 cc. in children) has been used routinely. Generally two injections have been necessary, one for lateral exposures, the second for anteroposterior views. Patients under 15 years of age are usually given a general anesthetic, and in adults a local anesthetic alone has been used routinely. There were no untoward reactions to the contrast medium. The procedure is not advised during the acute phase of cerebral accidents. The importance of cerebral angiography in the recognition and localization of intracranial aneurysms cannot be overemphasized. It is the only certain method of making that diagnosis preoperatively and is the only hope of identifying multiple intracranial aneurysms before operation or death. Congenital, arteriosclerotic and cavernous sinus arteriovenous aneurysms, their symptomatology, differentiation and complications are described. Six illustrative cases are reported; they stress the angiographic recognition of hemorrhage into the sylvian fissure. Confusing variations in the appearance of arteriosclerotic and arteriovenous aneurysms of the cavernous sinus are illustrated. Less common than cerebral aneurysms or brain tumors, angiomatous malformations lend themselves beautifully to diagnosis by cerebral angiography. Six illustrative cases are given. Occlusion of the carotid artery is frequently unsuspected clinically but may be readily diagnosed by cerebral angiography. The displacement patterns of tumors in various portions of the brain are illustrated by 12 cases. Meningiomas produce angiographic patterns which may vary greatly depending on the vascular bed of the tumor. The angiographic patterns of oligodendrogliomas may be similar to those found in glioblastoma multiforme. Metastatic adenocarcinoma of the brain may be unusually vascular and readily demonstrable by cerebral angiography.

Abdominal Arteriography.—Wagner and his co-workers employed a simple technic of abdominal arteriography using a 15 cm. 18 gage malleable needle and a hand syringe for injection in 26 consecutive instances. Indications for this roentgenologic study in cases of aneurysm, aortic occlusion, peripheral vascular disease, abdominal tumors, hypertension and hydro-nephrosis associated with aberrant vessels are discussed and illustrative arteriograms are presented. Although abdominal arteriography was performed without untoward reactions in this series, it is not without potential dangers. It should be employed as a diagnostic adjunct by carefully trained personnel only after simpler and standard studies have failed.

Radiation Treatment of Carcinoma of Cervix Uteri.—Lampe reports the survival experience in 1,130 patients with carcinoma of the cervix uteri after radiation treatment consisting of a combination of external roentgen irradiation followed by vaginal and uterine radium irradiation at the University of Michigan. The data on survival, calculated on an "absolute" basis, are presented for each year of the twelve year period 1932 to 1943, inclusive, by means of survival curves in which the years after treatment are plotted along the horizontal axis and the percentage survivors along the vertical axis. Comparison of results for each of the twelve years, following elimination of the effect of variation in frequency distribution of anatomic extent by means of the so-called "standardized" survival curve, demonstrates the "absolute" five year survival percentage to have risen from between 20 to 25 per cent for the years 1932 to 1935 inclusive to above 40 per cent for the years 1938 and 1939. Study of the four, three and two year survival curves indicates that this gain is essentially maintained for the years 1940 to 1942 inclusive. Analysis of the survival curves for the twelve years shows that prediction of five year results on the basis of three year survival figures may be misleading unless there is some evidence to indicate that the shape of the survival curve has not altered. The decreasing survival percentages with increasing anatomic extent of the neoplasm is well demonstrated by the survival curves calculated for each clinical group. The distribution of the cases among the grades of histopathologic differentiation is not significantly different among the twelve years. Some evidence is found which suggests that the results are better in the less well differentiated neoplasms. This suggestion cannot be accepted as proved, since analysis shows that the difference in results may be due solely to sampling variation.

Periosteum for Repair of Fascial Defects in Paratibial Region.—Giannestras presents the histories of 2 men, aged 23 and 24, respectively. In 1 patient a mass had appeared at the midportion of the leg just lateral to the edge of the tibia after the cast was removed following a compound fracture. After the man returned to work this mass became larger and painful. The condition was diagnosed as muscle hernia. A curved incision was made on the lateral aspect of the leg, and a defect of the fascia was found at the level of the midshaft of the tibia.

This defect permitted protrusion of the underlying musculature through the opening. There was thinning of the fascia. An attempt was made to reattach the fascia to the periosteum, but this was impossible. An incision was made on the periosteum at its medial edge, and a flap was lifted and attached to the fascia. After closure of the wound a cast extending from the toes to the mid thigh was applied to the leg, with the ankle at 90 degrees dorsiflexion and the knee at 15 degrees flexion. The cast was removed at the end of six weeks. During this time the patient was not permitted to bear weight on the extremity. Following removal of the cast, active weight bearing was permitted. Fourteen months after the operation, when control biopsies were made at two sites, it was found that the area of operation was well healed. A new layer of tissue covered the anteromedial surface of the tibial shaft, and this tissue was well adherent to the bone. Microscopic sections were made of both biopsy specimens. In neither case was bone developed by the transposed periosteum, although the literature indicates that periosteum begets bone. The periosteum remained attached along the entire length of the graft, thus maintaining a good circulation, which may explain why the periosteum did not go on to produce bone.

Correction of Scar Contractures of Hand.—Greeley says that all incisions, suture lines and skin graft edges must be calculated so that they will fall either transversely or obliquely across the longitudinal axis of the flexor or extensor surfaces of the hands and fingers. If this design is carried out and a postoperative shortening of the suture line should occur, the pull will lose its force in a lateral direction and therefore will not interfere with the normal flexion and extension mechanisms. Whenever possible, local tissues should be used for reconstructing hand contractures. Normal hand skin withstands daily trauma better, and sensation is more nearly normal. Stereognosis can never be replaced by skin grafts from other areas, because the special organs for this sensation are found only in the pacinian corpuscles located normally in the finger pulps. Consequently, when correcting linear contractures wherein there is sufficient available skin along the borders, a single or multiple Z-plasty will give the best results with minimum surgery. Free full-thickness skin grafts give the best surface-bearing qualities and maximum degree of elasticity on flexor surfaces. Thick split-thickness grafts provide adequate covering for extensor surface defects and are preferred in this area because of the simpler technic associated with their use. The use of pedicle flaps is reserved for instances in which it is necessary to carry subcutaneous fat with the skin grafts. This condition arises primarily in covering exposed tendons, bone or joints, or when it is planned to reelevator the graft at a future date for the purpose of carrying out subsequent tendon, bone or joint surgery.

Correction of Facial Paralysis.—Adams points out that in paralysis of the facial nerve the larger the number of different muscles which can be brought into play, the better the function one will be able to restore to the paralyzed area. The masseter muscle is most suitable for reanimating the corner of the mouth and the lower part of the paralyzed face. By transplanting the end of the insertion of the muscle at the lower border of the mandible, one is less likely to disturb the nerve supply and the pull is in the desired direction. The temporalis muscle is utilized to restore support and function to the paralyzed upper and lower eyelids. Again, the end of the insertion of the muscle is transplanted. Some patients with facial paralysis have extremely active muscles of the brow and forehead. An active forehead on one side, in contrast to the blank immobility and drooping lid and brow of the paralyzed side, presents a conspicuous disfigurement. By transferring a muscle flap of the active frontalis to the muscle bed of the paralyzed eyebrow, attaching it just beyond the midline of the forehead, one can not only support and elevate the drooping brow but also restore some degree of upward motion in this area. The following facts should be borne in mind in the transplantation of muscle flaps: the flaps should be of sufficient size to insure the necessary strength and support to the paralyzed region; the tension on the flaps should be ample to insure support and motion. Undue

stretching may lead to ischemia of the flaps; too much angulation of the pedicle might interfere with its circulation. In separating the muscle fibers to form the flap care must be taken not to disturb the nerve supply any more than necessary.

Hyperventilation.—Engel and his co-workers studied the symptoms developing during hyperventilation in patients with this syndrome and in medical students and staff members between the ages of 20 and 35 years in whom the same symptoms were reproduced by voluntary hyperventilation. Hyperventilation may occur as a response to certain intense emotional experiences in normal persons, as a vegetative neurotic symptom, as a hysterical symptom, as a symptom of diffuse encephalopathy and the action of certain drugs and as a response to anoxia. The symptoms may be divided into those related to reduction in consciousness and those related to tetany. Reduction in consciousness is observed to correlate well with the degree of slowing of frequency of the electroencephalogram and is usually pronounced when the mean frequency is reduced below 5.0 per second. Slowing of the electroencephalographic frequency during hyperventilation is more decided with rapid reduction in arterial carbon dioxide content, low blood sugar, low oxygen tension of inspired air, the erect posture, amyl nitrite and glyceryl trinitrate. Conversely, high blood sugar, high oxygen tension and the recumbent posture diminish slowing of the electroencephalogram. Intravenous injection of calcium chloride and nicotinic acid has no effect on the electroencephalogram during hyperventilation. Tetany is unrelated to changes in the electroencephalogram and occurs with longer periods of hyperventilation. The numbness and tingling probably are also peripheral in origin. Actual syncope is unusual during hyperventilation. Four different mechanisms have been observed, namely, concurrent or delayed vasodepressor syncope, accentuation of already present orthostatic hypotension, hysterical syncope and central type.

Streptomycin in Tuberculosis in Human Beings.—McDermott and his co-workers treated 17 patients with bacteriologically proved meningeal, miliary or other forms of generalized hematogenous tuberculosis with streptomycin. A constant daily dose of 3 Gm. of the drug administered intramuscularly in six or eight divided doses was used in 12 adults. In 5 children and infants the dose was adjusted to body weight (20,000 micrograms per kilogram). The total period of treatment was one hundred and twenty days. Patients with meningitis received streptomycin intrathecally as well as by the intramuscular route. Individual doses of 0.1 Gm. of streptomycin were administered at intervals ranging between twenty-four and seventy-two hours for total periods of sixty to ninety days. The administration of streptomycin was followed in every instance by a striking alteration in the course of the infection. Six of these patients (2 with meningitis, 2 with miliary and 2 with other forms of generalized hematogenous tuberculosis) have attained complete remissions which have been maintained for five to twelve months after the completion of the treatment. A seventh patient is apparently recovering one year after an acute miliary infection. In another 7 patients, all with miliary tuberculosis, death resulted from their infection. The remaining 3 patients have only recently completed treatment. Meningitis was present or appeared during treatment in 7 of 13 patients with miliary tuberculosis but was the principal cause of death in only 2 instances. In all 4 patients from whom bacilli resistant to streptomycin *in vitro* were obtained the

miliary infection resumed a progressive course, which terminated fatally despite further treatment with streptomycin. Microscopic and bacteriologic examination of the tissues in 6 of the fatal cases revealed changes which could be correlated with the clinical, bacteriologic and roentgenologic state of the infections at the time of death. Until more information is available it seems advisable to limit the period of streptomycin therapy to six or eight weeks. Although this procedure may increase the chance of post-treatment relapse, it should appreciably decrease the risk of relapse with streptomycin-resistant organisms.

Aspergillosis.—Cawley reports a unique case of aspergillosis with extensive and widespread involvement of various structures in a boy aged 7½ years. On admission to the hospital he had pneumonia of the lower lobes of both lungs and demonstrable evidence of a cerebellar lesion, which was found on surgical intervention to be an abscess from which *Aspergillus fumigatus* was cultured. Death occurred eight months after admission despite intensive and protracted treatment with penicillin, various sulfonamide compounds, potassium iodide and inhalations of ethyl iodide. Necropsy revealed abscesses of variable size involving the brain, dura, heart, lungs, mediastinum, lymph nodes, spleen, liver, right kidney and right ankle. Invasion by the mold of such structures as the myocardium and kidneys was especially remarkable. Consistently normal results from laboratory studies, with the exception of cultures positive for *A. fumigatus*, were a feature of the disease process. The aspergilli, a genus of molds, are notorious as laboratory contaminants. On rare occasion, as in the author's case, they may be the etiologic agent in production of a specific disease. Manifestations of aspergillosis are protean, and the diagnosis may be difficult. The lungs are the most frequent localization of the primary involvement. Treatment is often disconcerting, there being no specific therapeutic agent.

Erythema Nodosum.—Favour and Sosman report 155 cases of erythema nodosum in 102 adults, 88 of whom were women, and in 53 children, 32 of whom were girls. The patients were between the ages of 3 and 66 years. The disease usually developed during the winter months. A known respiratory infection antedated erythema nodosum in 126 (81 per cent) of the patients. The lag between the infection and the onset of erythema nodosum was usually two to four weeks. In half of the patients for whom cultures were done, beta hemolytic streptococci were grown in material from the throat. Tuberculosis was an uncommon antecedent infection and rheumatic heart disease a rare sequela. Migratory polyarthritis was a part of the clinical picture of erythema nodosum in 80 of the adults and in one third of the children. Isolated attacks of pains in the joints preceded and followed erythema nodosum. Ten per cent of the patients had a chronic form of the disease lasting from months to years. Mild secondary anemia, cervical adenopathy and occasionally enlarged hilar or bronchial nodes characterized the illness. Erythema nodosum may be considered as a hypersensitivity disease. Individual predisposition, a variety of infectious and chemical agents and local trauma contribute to its occurrence. It is not a form of rheumatic fever.

Marfan's Syndrome.—Tobin and his co-workers report 2 cases of arachnodactylia (Marfan's syndrome) associated with dissecting aneurysm of the aorta in a man aged 22 and in a woman aged 35, both of whom died as the result of the aneurysm. These 2 cases together with 4 previously reported make a total of 6 in which there were aortic lesions in the 14 necropsies performed on patients with arachnodactylia. These figures are significant if it is considered that 5 of the 8 patients without aortic lesions were under 28 months of age and that those with aortic lesions were between 14 and 35 years of age. The cardiovascular lesions demonstrated on necropsy included aortic medial necrosis and endocardial lesions which simulate those of rheumatic fever. The former is the more dangerous, resulting in dilatation of the aortic valve ring, the sinuses of Valsalva and the ascending portion of the aorta. Death may occur suddenly from dissecting aneurysm and rupture of the aorta. The role of the endocrine gland, particularly the hypophysis, remains obscure, but in both of the author's cases the hypophysis appeared to contain more than the usual proportion of eosinophilic cells.

Skin Tests in Pulmonary Disease.—Groover and his co-workers made skin tests with tuberculin, histoplasmin and coccidioidin on 1,220 patients with roentgen evidence of pulmonary disease compatible with that of pulmonary tuberculosis. Ninety-three and six-tenths per cent were sensitive to tuberculin, 58.6 per cent were sensitive to histoplasmin and 31.1 per cent were sensitive to coccidioidin. Seven patients in the group were strongly sensitive to histoplasmin and gave negative reactions to tuberculin (0.1 mg. of purified protein derivative) and coccidioidin. The lesions in all 7 were similar, with characteristics of tuberculosis, except for the absence of acid-fast bacilli in the bronchial secretions and of sensitivity to tuberculin. Efforts to isolate a fungus characteristic of *Histoplasma capsulatum* by microscopic examination and mycologic studies of bone marrow, sputum and lymph nodes of the patients with a strong sensitivity of the skin to histoplasmin were consistently nonproductive. Patients with a strong reaction to histoplasmin in a 1 to 1,000 dilution usually showed a mild reaction to coccidioidin in a 1 to 10 dilution; those with a strong reaction to coccidioidin in the 1 to 1,000 dilution usually had a mild reaction to the 1 to 1,000 dilution of histoplasmin. This cross sensitivity reaction is also suggested by the geographic distribution of patients with and without sensitivity to histoplasmin. The incidence of pulmonary calcifications was greater in the group sensitive to histoplasmin than in the groups sensitive to coccidioidin or tuberculin. Of 528 patients for whom a presumptive diagnosis of pulmonary tuberculosis was made by roentgen studies, 117 were observed to have acid-fast bacilli in their bronchial secretions or in gastric washings. The use of the skin sensitivity test to histoplasmin is of limited value in the differential diagnosis of pulmonary disease.

 *Nature of Glaucoma. H. Elwyn.—p. 506.
 Contact Lenses for Correction of Myopia Complicated by Lesions of Retina and Choroid. P. Tower.—p. 521.

Nature of Glaucoma.—Elwyn thinks that glaucoma is a heredoconstitutional functional disease, involving primarily the function of central regulation of the intraocular pressure. In some persons the central regulation becomes unstable as a result of inherited influences at about middle age or earlier. Impulses from the center reach the effector organ in the eye in normal numbers at times and in smaller numbers at others. As a result, the chemical mediator acetylcholine is produced in an irregular manner at the nerve endings in the effector

organ. The intraocular pressure is normal at times and high at others. The normal intraocular pressure is maintained by the constant volume of the aqueous in the chambers of the eye and by the constant volume of blood in the choroidal vessels. These constant volumes are maintained by the activity of the effector organ in the eye, which consists of three units: the ciliary body and the angle of the anterior chamber with its venous system, which maintain the constant volume of aqueous, and the choroidal vessels, which maintain a constant volume of blood in the choroid. When insufficient impulses from the central regulation reach the units of the effector organ, either the constant volume of the aqueous is increased or the constant volume of the blood in the choroidal vessels is increased, or both are increased. The result is glaucoma with a normal anterior chamber when the increase in the volume of the aqueous predominates, or glaucoma with a shallow chamber when an increase in the constant volume of blood in the choroidal vessels predominates.

Pathogenicity of Bagasse.—Bagasse is sugar cane from which the sugar content has been extracted. This material is stored in the open for months and even years; then it is broken and processed into building and insulating boards. Workers breaking bagasse sometimes acquire a respiratory disease characterized by cough, dyspnea, occasional hemoptysis, night sweats, chills and intermittent low fever. Roentgenologic examination of the chest shows miliary mottling throughout both lungs. Most of the patients recover after prolonged illness. Gerstl and his associates report results of studies undertaken on rabbits and guinea pigs to determine the pathogenic properties of bagasse fibers and of the microbial contents of representative suspensions. The possibility that hypersensitivity may play a role was also explored. Intravenous, intratracheal and intracutaneous tests were made. Final interpretation of these experiments has to be postponed until more information concerning the pathogenicity of the micro-organisms and of the fibers will be available. They found that bagasse fiber itself is a rather inert material, that the acute inflammatory process is due to micro-organisms, probably fungi, attached to the bagasse, and that the lesions never resemble those of silicosis.

Ductus Arteriosus and Arteriosclerosis.—The 175 post-mortem specimens on which this report by Blumenthal is based were obtained from fetuses and from persons of various ages. The ductus arteriosus or the ligamentum arteriosum arteriae pulmonalis was removed intact, fixed in solution of formaldehyde U. S. P., sectioned, and stained with hematoxylin and eosin. Many sections were also stained with the Van Gieson or with the elastin H stains to demonstrate more clearly the elastic, muscular and connective tissues. On the basis of the observations it is concluded that the ductus arteriosus is a true muscular organ which on stimulation is capable of contracting strongly enough to obliterate its lumen. The stimulation is apparently the increase of the oxygen saturation of the arterial blood brought about by the onset of respiration in the newborn infant. After the contraction has been maintained for several days, muscle tissue is replaced by tissue of a lower order of specialization. In some cases the replacement is slow and necrosis does not occur; however, in others rapid degeneration with necrosis and calcification takes place. The cause of this tissue replacement and degeneration appears to be relative anoxemia of the wall of the ductus brought about by contraction

of the muscle. This contraction narrows the lumen, compresses the vasa vasorum and thus decreases the blood supply of the vessel wall. These tissue changes occurring in the ductus arteriosus as the result of anoxemia seem to be similar to those observed by Hueper in arteriosclerosis. Anoxemia plays a large part in arteriosclerotic processes and may possibly be the fundamental mechanism through which the various causal agents bring about arteriosclerotic changes.

Thrombocytic Acroangiothrombosis.—Fitzgerald and his co-workers report 3 cases of platelet thrombosis of the capillaries, arterioles and venules in 2 white men aged 34 and 24, respectively, and in 1 Negro aged 27. Death occurred in the first patient five weeks from the onset of the patient's illness; the second patient died ten months after the onset of urticaria and vague generalized complaints and one week after acute symptoms appeared. The third patient died one month after the onset of slight joint pains and two weeks after an acute episode with vomiting, a macular rash over the face and neck, red urine and epistaxis following the administration of a sulfonamide compound. Necropsy was performed in all the cases. The pathologic data, clinical aspects and hematologic studies in these 3 cases and in 9 previously reported cases are discussed. It is believed that there exists a definite disease syndrome characterized clinically by fever, decided anemia, purpura; thrombocytopenia, involvement of the central nervous system and progressive fatal course of a few weeks' duration. •Microscopically, the presence of platelet thrombi in the capillaries, arterioles and venules is pathognomonic. The disease can be definitely differentiated from idiopathic thrombocytopenic purpura only by microscopic demonstration of platelet thrombi. Diagnosis of the disease can be made by bone marrow biopsy or by skin biopsy. If a case is diagnosed and the patient does not respond to conservative treatment, splenectomy should be considered. Spleens removed for thrombopenic diseases should be examined for platelet thrombi. Proper evaluation of splenectomy in this disease would be aided by follow-up study of cases showing platelet thrombi. The term "thrombocytic acroangiothrombosis" is suggested for this disease.

Thrombotic Thrombocytopenic Purpura.—Singer and his co-workers report 1 case of thrombopenic purpura associated with multiple platelet thrombi in a white girl aged 11, who died three weeks after the onset of the disease. Thrombotic thrombocytopenic purpura is the name proposed for this rare but well defined disorder which manifests itself clinically as an acute febrile disease and which is characterized by petechiae and ecchymoses, thrombopenia, prolonged bleeding time and poor clot retraction; by a severe anemia out of proportion to any observed blood loss; by mild acholuric jaundice, hepato-

splenomegaly; by bizarre and intermittent mental and neurologic symptoms and signs, and by transient leukemoid reaction in the peripheral blood. This clinical picture must be correlated with a remarkable microscopic pattern, namely, the presence of myriads of platelet thrombi in the small arterioles and capillaries of almost all organs of the body. Eleven such cases have been reported in the literature. Differential diagnosis from aplastic anemias of the idiopathic or of the symptomatic type, from diseases with invasion of the bone marrow by foreign cells, from Werlhof's disease (thrombopenic purpura), from allergic purpura and from infectious or toxic thrombopenic purpura is discussed. It is emphasized that if the physician is familiar with this rare syndrome a correct clinical diagnosis may become readily possible.

Quinacrine Suppressive Medication.—Baker and Platt report that the 147th Infantry Regiment served on various islands of the Pacific from the first half of 1942 to September 1945. A period of heavy exposure to malaria was followed first by six months' withdrawal of suppressive medication, then by eighteen months of well-controlled suppressive quinacrinization, with little or no fresh exposure, and finally by terminal dequinacrinization. Previous observations of the same troops proved that it was not safe to stop quinacrine for at least six months after exposure. It is generally accepted that four weeks of suppressive quinacrine medication following the acquisition of infection caused by *Plasmodium falciparum* prevents all further clinical activity. It appears from these observations that suppressive quinacrine medication for eighteen months after significant exposure exerts a comparable effect on some but not all cases of infection due to *Plasmodium vivax*. This confirms the general belief that heavily seeded troops should be taken off suppressive medication cautiously. If the relapse characteristics of the strains involved resemble those of Guadalcanal strains, troops should not be taken off for at least six months. From then on suppressive medication should be withdrawn only from sample fractions to obtain some indication of the remaining relapse latencies. After two years it is probably safe to discontinue the suppressive drug program for all troops at the same time.

Diagnosis of Bulbar Poliomyelitis.—According to Boines, partial or complete involvement of any of the cranial nerve nuclei in poliomyelitis is referred to as the bulbar form. The cranial nerves most frequently involved are the eleventh, the tenth, the ninth and the seventh. A table which lists the distribution of paralysis in 90 paralytic cases indicates that the lower extremities head the list in being the most susceptible part of the anatomy. The upper extremity is second, and the

sternomastoid is third. Paralysis of swallowing and speech is exceedingly frequent in the bulbar type. Of the 90 paralytic cases, 67 represented spinal and 23 bulbar involvements. There were 8 deaths among the 23 patients with bulbar poliomyelitis. The spinal fluid usually shows pleocytosis in the bulbar cases, but otherwise laboratory methods are of little value in the diagnosis. Early thorough examination of the muscles supplied by the cranial nerves is most important for the diagnosis. The rapid development of the symptoms in bulbar cases makes early hospitalization important. This may make it possible to save the patient with special nursing care and treatment.

Osteoid Osteoma.—Sherman says that although instances of osteoid osteoma had been reported under other names, it received little attention until Jaffe published an account of this lesion in 1935. The disease occurs mostly in adolescents and young adults. It is nearly twice as frequent in males as in females. The chief physical manifestation is that of tenderness. Roentgenographic examination of a mature lesion reveals that the active nidus is usually a small round or oval area of reduced density. About this nidus a thick, dense shadow of sclerotic regional bone is almost always present. The author presents 5 case histories which illustrate most of the characteristics of this lesion. Most authors are in agreement with Jaffe that it is a distinct entity. There exists, however, no such agreement as to whether the lesion is a benign neoplasm, as Jaffe contends. Brown and Ghormley, on the basis of 24 cases which they considered examples of the condition described by Jaffe, consider such lesions as chronic bone abscesses. Sherman admits that photomicrographs of material removed from 10 of the patients of Brown and Ghormley justify this conclusion, but she does not regard as reasonable the contention of these authors that all osteoid osteomas are solitary chronic bone abscesses. She believes that the weight of evidence is clearly against infection as the etiologic agent. The patients never have fever, leukocytosis or other systemic manifestations. When swelling is present, the area is only occasionally warm and there is no redness. The lesions are always solitary and never recur after complete excision. The wounds invariably heal after operation by first intention. The author agrees with Jaffe that osteoid osteoma is not of infectious origin but is probably best interpreted as a benign tumor.

Chondromalacia Patellae.—The study by Bronitsky is based on 29 cases in which degeneration of the patellar cartilage was verified at operation. Chondromalacia of the patella can be a disabling disease in a young, otherwise healthy person. In a patient in his early twenties with a history of chronic knee discomfort which does not respond to conservative treatment and which includes weakness, tendency to locking, occasional swelling of the knee and pain, especially on the medial side of the joint, the diagnosis of chondromalacia of the patella must be considered. If patellar crepitation or grating is present, this diagnosis can be made with greater certainty. Patellarplasty or chondrectomy, combined with some form of covering for the articular surface, gave consistently poor results. The surgery of choice is either a partial chondrectomy or patellectomy. Chondrectomy gave good results in 75 per cent and excision of the patella in all cases except one, where a primary synovitis was present. When synovitis is present with patellar chondromalacia, synovectomy is not required, since this condition usually clears up after excision of the patella. The decision as to the type of operation to be performed will have to be made frequently after the knee joint has been exposed. Chondrectomy should be reserved for cases in which the patellar cartilage and surrounding soft tissue are involved. In cases in which there is a severe involvement of the synovial tissue, patellectomy will give best results. Free bodies and torn menisci should be removed. The youngest patient in whom a patellectomy was performed was 13 years of age; the oldest patient was 36. The functional results were always good.

Internal Fixation of Bone and Neurorrhaphy.—Massie and Ecker had under their care in 1945 more than 200 cases of severe nerve lesions associated with fractures of the long bones. This group included 84 cases of fracture of the humerus in which exploration of the radial nerve was carried out within a few weeks of injury. In all except 2 either neurolysis or satisfactory anastomosis was performed. Of the total group of 84 cases, 41 required neurolysis only; 35 required nerve suture only, and 8 required internal fixation of the bone with shortening and nerve suture. Each of the 8 cases presented a lesion of the radial nerve associated with a compound fracture of the humerus. This report is confined to an analysis of the 8 cases in which treatment was by neurorrhaphy and bone shortening within sixty days of the injury on the average. Bony union was complete in all cases. Nerve regeneration was progressing satisfactorily but was complete in only 2 at the time the patients were last seen. The importance of early and adequate galvanic stimulation of paralyzed muscles is stressed. No ill effects are demonstrable from shortening of the humerus up to one-fifth of its length. Early suture of the nerve is of paramount importance. When suture necessitates prohibitive tension on the nerve, either at operation or during postoperative stretching, concomitant shortening of the bone in the arm is feasible. This is considered preferable to tendon transplantation in the forearm at a later date.

Nitrogen Mustard in Mycosis Fungoides.—Kierland and his associates report 6 patients with mycosis fungoides treated with nitrogen mustard, methyl-bis(beta-chloroethyl)amine hydrochloride. In 4 of these patients the condition had become resistant to roentgen therapy. One patient died of apparently unrelated causes shortly after a course of nitrogen mustard was given. The general condition and the cutaneous lesions of the other 5 patients improved after treatment. Three patients have had two courses of the drug. A remission of more than four months' duration has been obtained in 1 patient. Reactions were frequent, acute and occasionally severe; but in all cases it was possible to complete a course of therapy without serious ill effects. The response of the individual lesions in the same person and of lesions of different persons to treatment with this agent vary greatly. The authors conclude that methyl-bis(beta-chloroethyl)amine hydrochloride in the treatment of mycosis fungoides is an adjunct to previously recognized therapeutic measures and is of particular value when roentgen therapy is no longer of benefit.

Subcutaneous Administration of Sodium Sulfadiazine.—Forbes and his co-workers say that because the gastrointestinal tract of infants is not suited for the absorption of sulfonamide drugs the subcutaneous route has been used since 1942 at the St. Louis Children's Hospital. Adult patients do not absorb sodium sulfadiazine readily from the subcutaneous tissues, but for infants and children administration by the subcutaneous route constitutes a satisfactory method. Blood sulfadiazine concentrations of any desired magnitude can be quickly achieved and easily maintained by this method. The rate of diffusion of sulfadiazine from the plasma to the cerebrospinal fluid in patients with meningeal infection is somewhat slower following subcutaneous administration in comparison to the intravenous method. This lag is not of sufficient magnitude to contraindicate use of the subcutaneous route for the great majority of patients with bacterial meningitis. In addition to adequate chemotherapy, hydration of the patient and alkalization of the urine may be accomplished concurrently via the subcutaneous route by proper adjustment of the volume of the solution and its content of sodium lactate.

Rheumatic Fever Recurrences.—Jackson and his associates attempted to determine the recurrence rate of a group of rheumatic subjects who have received special attention to improve their diets and level of environmental care, but who have not received sulfonamide drugs to prevent intercurrent infections. They hoped to evaluate the relation of environmental factors to the course of the disease and to learn whether a high level of general care is sufficient to protect the children from recurrences, or if some children also should receive chemotherapeutic agents for prophylaxis. The 266 patients studied by the authors were under observation nearly nine hundred person-years. The major recurrence rate, although low, was higher than the rate for patients given sulfonamide prophylaxis. It was concluded that if the disease is definitely inactive an excellent diet and wholesome living conditions will practically eliminate the chances of a recurrence with carditis, and that sulfonamide prophylaxis is indicated for children who have recovered from rheumatic fever but have had carditis and are forced to live in an environment which does not provide a good diet and at least a fair level of general care.

Rabies.—The case of rabies reported by Duffy and his associates concerned a boy aged 13 months, who was hospitalized because of fever, refusal of food, irritability, restlessness and disorientation, all of twenty-four hours' duration. He had been well previously. The infant died on the fourth day after the development of symptoms. Samples of spinal fluid, blood and saliva were obtained a week before death. Diagnosis of rabies was established by isolating rabies virus from the saliva. The untreated saliva when injected intracerebrally into mice killed the animals within twenty-four hours. The same saliva when mixed with penicillin and inoculated intracerebrally permitted 3 of the 7 mice inoculated to survive long enough that the virus could be recovered. The agent isolated from the saliva was known to be rabies virus by the demonstration of Negri bodies in the brains of mice and by neutralization tests. The virus was not isolated from the cerebrospinal fluid or blood. This case illustrates how confusing the diagnosis of rabies can be when no clearcut history of exposure is obtained.

Gas Shadows in Wounds.—McDonald reports on 146 casualties from a severe explosion examined with roentgen rays. Twenty-one of those with compound wounds had evidence of gas shadows in their soft tissues. Such shadows in soft tissues can be produced (1) by the introduction of air with a foreign body, (2) by enclosing air at the operative closure of skin flaps and (3) by anaerobic clostridia. In this series there was not a single case of proved infection by pathogenic anaerobes. A roentgenologic differential diagnosis between a pathogenic and a saprophytic gas-forming bacterium cannot be offered, except that the presence of air in the first several hours is more likely to be mechanical; its rapid extension and linear spread in the muscle planes suggest pathogenic infection. The vast majority of gas shadows in roentgenograms probably represent benign saprophytic or nonpathogenic contamination. The patients would recover regardless of the therapeutic use of roentgen rays, gas serum or possibly even sulfonamide compounds. Too often the mere presence of clostridia, even pathogenic, has been taken to prove the imminence of a fulminating gas infection. Clostridial contamination occurs in 20 to 30 per cent of war wounds, and yet in only 0.4 per cent does gas gangrene develop. In addition, the soft tissues in about 15 per cent of all compound wounds show roentgenologic evidence of gas; at follow-up these shadows appear to be benign and do not represent true gas infection. The author thinks that the significance of gas in wounds

Distribution of Poliomyelitis Virus.—Wenner and Tanner studied 20 persons in four households in which poliomyelitis had appeared for the distribution of the virus. They found that 16 had poliomyelitis virus in their intestinal discharges, and among these 16, 7 had virus in the oropharynx. Of 12 children in these families, each had poliomyelitis virus in the stool specimen; 5 had virus in the oropharynx. Of the 8 adults 4 had poliomyelitis virus in stool samples, and in 2 of these 4 the virus was detected in the throat. Poliomyelitis virus was not found in the remaining 4 parents. The history of onset of illness suggested that infection occurred in these households as a result of exposure at a common source.

Antibodies in Vitamin Deficiency States.—Axelrod and his associates found severe impairment of antibody response in pantothenic acid and pyridoxin-deficient rats. Variable but low titers were observed in the riboflavin-deficient groups. Consistently high titers were noted in both the inanition controls and the ad libitum-fed animals.

Uneven Distribution of Glycogen in Liver.—Gomori and Goldner stress that great caution is warranted in judging the metabolic state of the liver on the basis of the glycogen content of biopsies, inasmuch as variations exceeding several hundred per cent may be observed in simultaneous biopsies taken from the same lobe of the rabbit's liver.

Influence of Oral Saccharin on Blood Sugar.—Kun and Horvath gave saccharin (sodium salt of *o*-sulfobenzoic acid imide) to human subjects in doses of 0.05 Gm. in 80 cc. of water. They found that this dose caused a decrease of 12 to 16 per cent in the blood sugar level of normal persons. Water alone had no significant influence. The decrease of blood sugar was not proportional to the dosage of saccharin. Administration of the

saccharin in four portions during a forty minute period increased the duration of hypoglycemia. Thus it seems that saccharin with its intensely sweet taste can cause a decrease in blood sugar, presumably through the reflex liberation of insulin.

Birth by Rectum in Abdominal Pregnancy.—Brown and Rucker report a woman, aged 25, in whom pregnancy had presumably begun with tubal implantation some time after August 1945. Tubal abortion with minimal internal bleeding and secondary placental implantation occurred before the appearance of vaginal spotting Nov. 15, 1945. The pregnancy prospered for a time but succumbed March 15, 1946, from lack of blood supply or trophoblastic invasion of the large bowel, or both. Contamination of the amniotic sac and peritonitis from bacteria present in the large bowel ensued. Laparotomy was contraindicated after the onset of peritonitis. During the entire forty-three day febrile period the amniotic sac was grossly infected, since it formed a communicating diverticulum with the rectum. The points of interest presented by this patient included: (1) the length of time between development of the rectoamniotic fistula and passage of the first fetal bones (nearly two months); (2) the onset of recovery despite presence of the fistula; (3) spontaneous closure of the fistula after the amniotic sac content was discharged, and (4) complete healing of the internal genitalia without obvious residual scarring.

Tetraethylammonium Chloride in Arterial Insufficiency.

—The experiments presented by Cooper and his associates were undertaken to determine the efficacy of chemical sympathetic blockage in experimental acute arterial injuries. In 30 adult mongrel dogs the aortic trifurcation was exposed. The terminal aorta was doubly ligated distal to the origin of the inferior mesenteric artery but proximal to the origin of the deep circumflex iliac arteries. Ligatures were placed around the two

external iliac arteries and the common hypogastric trunk. The intervening arterial trunks were excised. The abdominal wound was closed in layers. Nothing further was done in the control group of 10 dogs, the animals being closely observed until the time of death. In the experimental group tetraethylammonium chloride was given intramuscularly in the proportion of 25 mg. per kilogram of body weight as a sterile 10 per cent solution. Similar doses were given every eight hours for three days. The observations indicate that chemical blockage of autonomic ganglions by the tetraethylammonium ion may be of value in acute arterial insufficiency following arterial injury, either as a substitute for other methods of sympathetic interruption or as a preliminary to them.

Heparin in Venous Thrombosis.—Loewe and his associates found that heparin therapy in experimental venous thrombosis in rabbits gave the following results: (1) early clots are completely resolved; (2) growth of the collateral venous circulation is tremendously enhanced, and (3) speed of recanalization after occlusive thrombus formation is accelerated.

Endometriosis of Intestinal Tract.—Sutler says that the recognition that ectopic endometrium may have a wide extragenital spread has made endometriosis a condition of general medical interest. Among 140,716 histologic diagnoses made by the pathology department of the University of Michigan during a ten year period, endometriosis was noted in 848 patients (0.60 per cent). The author is convinced that this histologically ascertained incidence is considerably lower than the actual incidence. It has been estimated that endometriosis exists in 10 to 22 per cent of all patients requiring gynecologic abdominal operations and in 8 to 15 per cent of all women during active menstrual life. The intestinal tract is a highly significant extragenital location for endometriosis. In the material studied this site was involved in 35 patients; the appendix in 25, the ileum in 1, and the rectosigmoid in 9. Cancer may be simulated by endometrial invasion of the intestine. The paucity of pathognomonic signs of endometriosis and its frequent occurrence as a coexistent lesion of lesser importance preclude a satisfactory percentage of correct preoperative diagnoses. Histologic examination will often remain the only certain means of confirming the diagnosis.

Resuscitation of Asphyxiated Newborn.—Atherton stresses that the primary requirement of the asphyxiated baby is oxygen. In severe asphyxia the larynx and pharynx behave like a collapsed tube, and air forced into the mouth will not penetrate the larynx efficiently. Removal of mucus and other debris from the mouth and pharynx is insufficient, because in most instances the trachea and bronchi are plugged. At the University of Tennessee intratracheal intubation is employed. The index finger is introduced, acting as a guide for a tracheal catheter, which is introduced through the larynx into the trachea. The trachea is then thoroughly aspirated as the catheter is withdrawn. The catheter is reinserted into the trachea, and the finger now makes pressure over the larynx and body of the catheter to occlude any reflux of air when it is blown into the trachea. Artificial respiration is carried out by gently blowing into the catheter at the rate of about twenty times per minute. The effort is continued just as long as there is a heart beat. Respiratory stimulating drugs are used only as adjuncts when the catheter technic does not give satisfactory results.

Allergens of House Dust.—In the first of their three papers on the allergens of house dust Rimington and his associates show that a procedure has been elaborated for the extraction from house dust and purification of the material giving positive dermal reactions in dust-sensitive persons. Hydrolysis with acid under suitable conditions liberated a reducing sugar identified chromatographically as galactose and a number of simple amino acids. The second report is concerned with a comparison that has been made of the reactions given by allergic subjects to purified house dust antigen, the pooled extracts of twenty-six strains of mold grown in pure culture, the culture fluids obtained from the latter, and also to materials predominantly polysaccharide in character isolated from four species of *Penicillium* and one species of *Calidiariomyces*. Some patients gave positive reactions to both house dust and mold products, others were sensitive only to house dust. No patient was sensitive to molds and insensitive to house dust. Examination of three of the nitrogen-containing polysaccharide materials from molds by chromatography after acid hydrolysis revealed the presence in them of several of the simple amino acids. In this respect they resembled, chemically, the purified antigen from house dust. In summary of the studies described in the third paper the authors say that "crude dust antigen" dilutions of 10^{-5} produced cutaneous reactions by intradermal tests in about 6 per cent of normal subjects and in 70 per cent of persons with allergic symptoms. Allergic symptoms of the respiratory tract seemed to be provoked by a dusty atmosphere in subjects with a threshold reaction to dust in dilutions not less than 10^{-7} . Sensitivity to dust and to other inhalants often occurred together in the same subjects. Among 80 allergic patients, none of those tested was sensitive to feather, cat hair or molds and not to dust. Many patients exhibited sensitivity to the dust antigen but not to molds or any other material tested. Eighteen allergic patients with perennial rhinitis and allied conditions who received a course of injections of dust antigen claimed improvement during treatment. The changes in the nasal mucosa did not return to normal. A decrease of the threshold reaction to dust was obtained during treatment.

Endocyme Fetus in an Infant.—Maxwell reports the case of an infant aged 4 months with a greatly enlarged abdomen. On palpation the upper two thirds of the abdomen was felt to be occupied by a large firm mass, which on opening of the abdomen was found to be inclosed in a thin-walled sac. When this sac was opened a fetus was disclosed. The weight of the fetus after removal was 1 pound 10 ounces (737 Gm.), and the infant's weight on the day after operation was 8 pounds 4 ounces (3,742 Gm.). The infant made an excellent recovery. Roentgenoscopy of the removed fetus disclosed a rudimentary spine and long bones.

Quartan Malaria Transmitted by Blood Transmission.

—Rogers states that a woman, aged 18, was given an antepartum blood transfusion. About eight weeks after this transfusion malaria developed. Typical Plasmodium malariae were observed in her blood smears. She was treated with quinine and quina-crine. Although the woman received the blood transfusion before delivery, the infant had shown no signs of malaria up to the age of 5 months. The blood donor had never had clinical malaria but had lived five months in a malarious area seven years before. The blood sedimentation rate was not elevated in the carrier of malaria.

Sputum Examination in Diagnosis of Pulmonary Tuberculosis.—The observations reported by Kirschner were made in the bacteriologic department of the Pasteur Institute in Java. He stresses that in patients with minimal lesions and in convalescents a sputum examination that is negative does not exclude the possibility of discharge of tubercle bacilli. In such cases repeated examination is advisable. To avoid this repetition

a rational method of sputum examination, gastric lavage or laryngeal swab is recommended. The method consists of collecting sputum for several days (three, seven or fourteen days, respectively) and using the entire sediment obtained by concentration for microscopic examination as well as for animal inoculation and/or culture. Experience has shown that in this way the chance of detection of tubercle bacilli in a single examination is much greater without further taxing the laboratory. Experiments carried out with artificially infected sputums revealed that the bacilli maintain their viability for at least seven to fourteen days at room temperature in the tropics. The same will apply for the temperate climate with its lower temperature, which preserves much better the viability of all organisms. Modification of the Ziehl-Neelsen staining technic is mentioned, which is technically no more complex than the original method but which facilitates the detection of tubercle bacilli.

Painful Shoulder in Coronary Disease.—Schott points out that in some patients with coronary disease a painful disability of one or both shoulders resembling scapulohumeral periarthritis is the outstanding symptom. If this occurs a short time after an attack of coronary occlusion during which pain radiated to the affected shoulder, the condition may wrongly be considered to be just the usual manifestation of myocardial infarction. The author reports 6 patients with coronary disease associated with a painful disability of the shoulder. Some relationship between these two conditions appears to exist although its mechanism is obscure. No single method of treatment has proved generally successful, and there is hardly a type of physical therapy which has not been suggested. In the acute stage the administration of morphine may be necessary. The arm should be rested in abduction. Infiltration of the painful area with a solution of 1 per cent procaine without epinephrine can be repeated daily and combined with the administration of acetylsalicylic acid. Manipulation under an anesthetic, which is contraindicated in the acute and subacute stages, is the method of choice and is often curative when limitation of movement persists owing to adhesions. It is suggested that examination for coronary disease of larger numbers of patients over 40 years of age with painful disabilities of the shoulder—especially the left—without obvious cause is desirable in order to establish the frequency and nature of this relationship.

Cervical Lymph Node Metastases of Oral Carcinomas.

—Weyde discusses the treatment of the metastases in the cervical lymph nodes from carcinomas of the oral cavity on the basis of histologically verified cases treated in the Norwegian Radium Hospital during the ten year period from 1932 to 1941, inclusive. There was a total of 386 patients. Three stages are differentiated on the basis of the presence and extent of metastases to the lymph nodes. The first stage is free of clinical symptoms of such metastases; in the second stage clinical metastases are limited and operable; in the third stage the lymph

node metastases show commencing fixation or have infiltrated into the surrounding structures, or they are bilateral and may be operable or inoperable. The author describes the treatment of the primary lesion and of the lymph nodes, with particular attention to "neck dissections." At the Norwegian Radium Hospital the indications for neck dissection are essentially those formulated by Duffy, although in certain cases a wider range of indications has been used. For instance, neck dissection is done when the tumor extends beyond the midline of the oral cavity as long as the primary lesion can be controlled. In stage I prophylactic neck dissection is not indicated. In stage II radiation treatment of the cervical metastases is started simultaneously with treatment of the primary tumor, and neck dissection is performed eight weeks later if the lymph node tumor has not disappeared. Neck dissections in operable metastases from highly differentiated carcinomas have a low mortality and little chance of recidivation. Patients with metastases from less well differentiated carcinomas, however, ought not to undergo operation. In stage III there is every reason to limit the treatment to palliative radiation.

Meningoencephalitis After Epidemic Parotitis.—Hodenpijl and de Jong observed in the course of an epidemic of mumps that in a city of about 100,000 inhabitants encephalitis developed as a complication of mumps only occasionally (10 cases), whereas in a neighboring town of 1,800 inhabitants encephalitis occurred in 18 of 50 persons with mumps. The most surprising aspect was that in 10 of the 18 children encephalitis appeared without there being signs of parotid swelling either before, during or after the onset of encephalitis. A number of these children, however, had brothers or sisters with mumps or had had contact with mumps patients in school. Spinal puncture was done in 6 of the patients and revealed increased pressure and a high number of lymphocytes. All patients recovered.

*Cavity Formation in Boeck's Sarcoid. A. C. Appelmann.—p. 2985.

Alimentary Hypoglycemia After Operations on Stomach.—Gerrits and Rodbard point out that spontaneous hypoglycemia can be elicited not only by adenoma of the islets of Langerhans but also by a great number of other factors. There exist organic and functional types of hypoglycemia. Alimentary hypoglycemia after gastric operations is grouped with the functional forms. The authors report the case of a man who had undergone gastric resection according to Polya-Reichel and who subsequently showed spontaneous hypoglycemia. They think that this condition probably is frequently overlooked. In this syndrome hypoglycemia often arises some hours after a meal rich in carbohydrates. Explanation of the alimentary hypoglycemia should be sought in nervous influences on the blood sugar level from the stomach and intestinal tract, which eventually may be expected to undergo pathologic changes.

Pulmonary Cavities in Boeck's Sarcoid.—Appelmann presents histories of 2 patients with Boeck's sarcoid, in whom pulmonary cavities developed. The first of the patients died less than two years after he was first seen by the author. The diagnosis of Boeck's sarcoid had been verified by biopsy, but although tubercle bacilli were searched for during life as well as at necropsy, they could not be demonstrated. In the second patient the search for tuberculosis likewise remained negative. The author admits that the roentgenogram in the reported cases differed somewhat from that seen in tuberculosis, but he also cites factors which suggest the possibility of a tuberculous etiology of Boeck's sarcoid.

Penicillin in Treatment of Meningitis.—Bacteria were found in the cerebrospinal fluid in 5 of Schmidt's 23 cases: 1 pneumococcus, 1 staphylococcus, 2 meningococci and 1 Hemophilus influenzae. Penicillin was given intracisternally once or twice daily and intramuscularly, together with "lucozil" (N'-[5-methyl-1,3,4-thiadiazol-2-yl]-sulfanilamide); the patient with staphylococcal meningitis died from the grave brain lesion, the one with influenza meningitis died a month later from hydrocephalus. Nine patients believed to have bacterial meningitis were treated similarly without waiting for the results of culture. All recovered except 1 patient with chronic purulent meningitis due to Proteus infection, presumably originated through congenital fistula. Because of lesions of the dura and the possibility of infection 9 patients were given penicillin prophylactically, in 5 cases intracisternally and intramuscularly, in 2 intramuscularly and in 2 by daily instillation through subdural drain; concomitant treatment with the sulfonamide drug was given in 5 instances; all recovered.

Acute Stenotic Laryngitis and Laryngotracheobronchitis in Children.—Arnesen and his associates report on 43 cases of pseudocroup in 26 boys and 17 girls aged up to 10 years. Boys predominated only in the first two years of life. The disease was almost epidemic, and protracted dyspnea occurred in many cases. Comparison is made with 14 cases of diphtheria croup in the same age group treated in the same period. Based on the degree of severity the cases of pseudocroup are divided in three groups. The 3 cases in the third group were characterized by a fulminant course after onset as a usual catarrhal infection; 2 of the patients died. Diphtheria could rarely be excluded on admission, and diphtheria serum was given in most cases. Except in the mildest cases sulfathiazole and penicillin were administered. The standard treatment was vapor and rest. Tracheotomy was done in the gravest cases. Effective suction apparatus was not available at the time. The usual acute stenotic laryngitis is regarded as probably a virus infection. There are indications that the grave forms are due to secondary infection with pyogenic microbes and that the severe course depends in part on the preceding virus infection. Leukocytosis was commonest in true croup, while a leukocyte count within the normal limits but with lymphocytosis dominated in pseudocroup. However, variations from these findings were seen.

Arterial Accidents in Penicillin Treatment.—Courty and Biscaye treated a woman aged 64 for infected eczema with 800,000 units of penicillin by the intramuscular route every three hours for five days. The eczema was considerably improved but recurred two days later. Penicillin treatment was repeated, with 200,000 units a day given intramuscularly combined with sulfathiazole. The eczema became worse, and sulfathiazole was discontinued while penicillin treatment was continued. On the

fourth day of the penicillin treatment an acute thrombotic arteritis was manifested in both lower extremities accompanied with a sudden rise of temperature to 104 F. (40 C.). Gangrene in the left foot made its amputation necessary. The patient had no previous arterial disturbance. A second case is reported, in which an acute obliterating polyarteritis occurred suddenly in a man with subacute venous septicemia of the lower extremities and spermatic cord but without any apparent arterial involvement. He had been treated for four days with 1,000,000 units of penicillin. Death resulted in twenty-four hours. It is suggested that these arterial accidents have been caused by shock due to the impurity of the penicillin employed or by sensitization that produces in an unstable vagosympathetic system an intense vasomotor response, which was particularly grave because of a preexisting latent arterial involvement, e. g., in case 1. The second case demonstrated that acute arteritis may occur and progress in spite of intensive penicillin therapy.

Gastric Secretion in Tuberculosis.—Capo Porcel says that although it is generally admitted that hypochlorhydria and deficiency in gastric secretion are frequent in tuberculosis, little attention has been paid to the importance and incidence of this factor. At the sanatorium for tuberculous patients with which the author is connected, studies were made on the gastric function of 100 patients at the time of their admission. Gastric acidity was tested following stimulation with histamine. Achylia resistant to histamine stimulation was detected in 24 patients, and another 33 patients had hypochylia. Gastric disturbances were more frequent in these patients than in those with normal acidity, but substitutional therapy with hydrochloric acid counteracted diarrhea and vomiting and improved the appetite. In 1 tuberculous patient with achylia, necropsy revealed atrophy of the gastric mucosa.

Sudden Death in Artificial Pneumothorax.—According to Codina Suqué and Martínez de Salinas acute accidents of the syncopal type that may cause sudden death have been known to occur during the induction of artificial pneumothorax ever since Forlanini first introduced this form of collapse therapy in pulmonary tuberculosis. Reports about the incidence of this accident vary from 1 to 10 for every 10,000 punctures. The fact that these accidents may result in sudden death has led to considerable speculation about their pathogenesis and possible treatment. The two most widely accepted causal theories are pleural shock and gas embolism. The authors report a tuberculous patient, aged 50, who died suddenly during the induction of an artificial pneumothorax. There was evidence that a spontaneous pneumothorax was the cause of the sudden death. The authors believe that the spontaneous pneumothorax produced the sudden death by way of an "acute cor pulmonale." The measure usually employed for the treatment of the syncopal attack presumably due to gas embolism, such as the elevation of the pelvis, not only is useless in this condition but may cause an exacerbation in that it brings about a more forced respiration with greater intake of air into the pleura. Likewise, cardiac and respiratory stimulants are of no use in the first few moments. The most urgent first measure is the prompt extraction of air by means of a perforated trocar.

- *Collective Food Poisoning in 130 Persons. H. Vaccaro, M. Pérez and J. Cabezas.—p. 495.
Cancer of Breast in Man. E. Duval C.—p. 525.

Collective Food Poisoning.—Vaccaro and his associates report an outbreak of food poisoning in 130 persons in a boarding school. Human carriers, contaminated food and contaminated drinking water were not found. *Salmonella typhimurium*

was isolated from the feces of 22 or 23 patients. Agglutinins against *S. typhimurium* in titers varying between 1:20 and 1:320 were found by serologic study in 114 of 116 cases but in none of the blood serums of 118 normal adults of the Chilean population (controls). Higher agglutinin titers were observed when the H antigen was used than when the O antigen was used. The results of agglutination reactions were the same for the rapid as for the slow methods. Seven months after the occurrence of the outbreak the patient's blood contained no agglutinins against *S. typhimurium*. In vitro studies showed that sulfaguanidine has no controlling effect on *S. typhimurium*.

Cushing's Syndrome in Girl Aged Twenty Months.—Weisse reports the clinical history of a girl who developed normally until about 15 months of age. After an attack of measles which was complicated by otitis media, the mother noticed a great increase in weight and in the growth of hair. The appetite was enormously increased, and the child became irritable. The skin assumed a bluish red color and venectasias appeared. There was macrogenitosomia, mild hypercholesterinemia and changes in the carbohydrate metabolism. After observation in the hospital the existence of a Cushing syndrome was no longer doubted, but the etiologic differential diagnosis posed difficulties. Further studies, particularly the demonstration of male sex hormone in the urine, suggested the presence of a tumor of the adrenal cortex. An operation was performed and disclosed a vascular tumor of the size of a hen's egg on the left adrenal gland. It was possible to leave the adrenal in place. The postoperative course was at first favorable. Then, the blood pressure decreased and the child died on the third postoperative day without responding to treatment.

Pernicious Anemia During Childhood.—Kade presents the history of a boy, who has been followed for nearly six years and is now 19 years of age. He came under observation at the age of 14. At that time there was lack of appetite, vomiting, fatigue, pallor, burning of the tongue and paresthesia in the hands. The results of a study of the blood and the deficiency of hydrochloric acid in the gastric juice suggested pernicious anemia. Treatment was instituted, and the patient could be maintained in a fairly normal status with continuous liver therapy. The author stresses that this was the only case of pernicious anemia involving a child in a total of 376 cases. The family history of the patient was investigated and revealed anemia in the sister, slightly increased erythrocytic diameter in the father, slight hypersegmentation in the mother and deficient gastric secretion in father, mother and sister. It is pointed out that the chronic anacid gastritis of patients with pernicious anemia may predispose to the development of cancer, as has been proved by necropsies in large numbers of cases. Continuous roentgenologic control of the gastric mucosa of patients with pernicious anemia is therefore emphasized by the author.

Book Notices

Intracranial Complications of Ear, Nose and Throat Infections. By Hans Brunner, M.D., Associate Professor of Otolaryngology, University of Illinois College of Medicine, Chicago. Cloth. Price, \$8.75. Pp. 444, with 95 illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1946.

The author is well qualified to write a book on this subject. Clinician, teacher and investigator, he has long been world renowned as an authority in this field.

The incidence of intracranial complications has sharply declined, due to obvious factors. One may differ with the author in his statement that the influence of chemotherapy (and antibiotics) in the prophylaxis of these complications is controversial. All can agree that the introduction of these new agents alters the customary symptomatology and renders the diagnosis and treatment of intracranial complications more difficult. Thus the great need for just such exact information as is presented in this volume is apparent, for there can be no substitute for exact diagnosis and rational therapeutic methods when such complications do arise.

Although the greater portion of the book is devoted to clinical aspects, the section on anatomy and physiology is equally excellent, presenting many fundamentals which are not available elsewhere, and which are of great importance in understanding the why and the wherefore of intracranial infections. The clinical chapters consider completely in orderly sequence the possible intracranial complications, starting with diseases of the dura mater and progressing inward to the venous sinuses, meninges and brain itself, which follow ear, nose and throat infections. Each subject is presented under the headings of pathology, symptomatology, prognosis and treatment. Everything is given with such clarity of clinical detail that the book will serve both as a classic textbook for various interested specialists and also as a specific reference.

Guide to Health Organization in the United States. By Joseph W. Mountain Medical Director, and Evelyn Flook, Administrative Analyst, U. S. Public Health Service. Prepared by Direction of the Surgeon General, Federal Security Agency, U. S. Public Health Service, Miscellaneous Publication No. 35. Paper. Price, 20 cents. Pp. 71, with 10 illustrations. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1947.

There is no "Health Organization" in the United States; there are many "health organizations." This little guide puts each of these organizations in its place relative to the others. At no point does it suggest that there should be a single Health Organization.

The authors look at national health from the point of view of the national government; this tends to suggest the usefulness of a single, all-inclusive agency at the national level "to do things right." This suggestion the authors have avoided, and they give their reasons:

When the general scheme of health organization is first explained, the visitor or casual observer often is amazed that it works at all. But it does work, even though at times the process may seem cumbersome and inefficient. Its high performance is well demonstrated by rather obvious and tangible results. The people of the continental United States now enjoy a level of health and well-being never before attained by any population of comparable size.

The health organizations described by the authors are those which comprise the setting within which the private practice of medicine is conducted. The authors do not suggest that the private practice of medicine should be impaired in any way; nor do they say anything whatever of compulsory health insurance.

The discussion of nongovernmental health organizations is short, perhaps because these organizations have been so well covered by other sources. The section devoted to health activities of federal agencies is the fullest. The discussion brings out an important feature of government geography sometimes overlooked by proponents of One Big Health Agency: the large number of federal agencies which have health functions in connection with other duties; functions which could hardly be removed from the agency without increasing confusion all around. Examples of this are the Tennessee Valley Authority, with malaria control functions which require altering water

levels in its lakes and which are therefore indissoluble from its navigation and flood control functions; and the Farm Home Authority, with programs for health in connection with rehabilitation of farmers of low income—rehabilitation which requires intimate knowledge by administrators of agricultural techniques rather than of health measures.

In presenting the picture of state health organizations the authors have met the problem of diversity by a simple tabular comparison, indicating the frequency of each type of organization.

The authors emphasize that there are 38,000 units of local government in the United States, apart from school and other special purpose districts. A neat bar-diagram device is used to present the picture of local health units, with state support where applicable. The authors use the following quotation from Mustard:

... The vast majority of routine health service received by the people of the United States is delivered by local agencies. The federal government may subsidize and indirectly shape local health departments, the state health department may determine major policies for local agencies, set standards, promulgate regulations and even directly supervise them, but the final determining factor in the effectiveness of a public health program rests with the workers in the locality where the problems are occurring.

Sinn und Gehalt der sexuellen Perversionen: Ein daseinsanalytischer Beitrag zur Psychopathologie des Phänomens der Liebe. Von M. Boss. Cloth. Price, 12 Swiss francs. Pp. 130. [Sole distributors for the U. S. A. and Canada: Grune & Stratton, Inc., 381 Fourth Ave., New York] Hans Huber, Marktgasse 9, Bern 16, 1947.

Dr. Boss is one of the outstanding members of a Swiss group who have in recent years been interested in what they term "existential analysis" (daseinsanalyse). In his discussion of the perversions Boss contrasts his theories with the psychoanalytic concepts and also with the so-called "anthropologic" theory of perversion. The exponents of the latter theory emphasize the nature of man (anthropos) as a total entity. They aim to study the human being in relation to his place in the "objective" world, eliminating "subjective" evaluations as much as possible.

According to Boss, the love life of man is to be considered as an entity rather than as a composite of many infantile and adult instinctual drives. He is evidently well versed in psychoanalytic theory, although he carefully avoids the use of psychoanalytic terminology in any of his formulations whenever possible. However, the clinical material makes it evident to the reader that he makes full use of his psychoanalytic knowledge in order to evaluate the patient's "existential" position. Although Boss does not actually deny this, he strives to formulate his theories entirely in terms of the conscious experiences of the patient and in somewhat vague cosmologic phraseology.

He concludes that sexual perversion is, in each case, the only possible means by which love can break through the otherwise impenetrable barriers previously imposed on the personality development by the environment. No matter how divergent from more normal love impulses, the perverse act itself is regarded as an attempt on the part of the patient to reestablish a positive affective relationship with the outside world and with other human beings, even when it is manifested in so remotely displaced a fashion as in fetishism.

In the discussion of psychoanalysis Boss confines the argument to the early writings of Freud as exemplified by the libido theory and does not at any time refer to the more recent contributions of psychoanalysis in relation to ego psychology. The emphasis is on the gross pathology of environmental influences, on the restrictions imposed on the erotic impulses by fear, shame and disgust, and on the ultimate break-through of love in a fashion peculiar to the needs of the individual as a whole. Boss differs with the so-called "anthropologic" psychologists in their explanation of the perversions as "a destructive reaction" (Gebässel), or as "a depreciation and deformation of accepted ethical values" (Straus). He does not consider hate as antipodal to love, but assigns this role to anxiety.

The clinical application of Boss's findings is not in itself new to American psychiatrists and psychoanalysts, since it is based on the one hand on something akin to psychobiology and on the other to that type of understanding of the deformation of the ego with which most modern psychoanalysts are fully conver-

sant. The point of interest lies chiefly in the emphasis not on the structure of the perversion but on its economic usefulness to the personality of the patient, so far as it constitutes his particular and only means of reasserting his love impulses, whatever their origins or structure. Boss regards the perversion as an attempt at restitution and an abortive effort to reestablish contact with reality and to wring some gratification from it, no matter how minimal. That this gratification is not simply of a somatic-erotic nature Boss is careful to emphasize, pointing out that the real need of the patient is not solely autistic but directed toward some kind of a common experience with other human beings.

In the aggregate Boss's clinical achievement seems roughly to parallel what is commonly called "psychoanalytically oriented psychiatry." The fact that Boss has had the training and experience of a psychoanalyst must be taken into consideration, and the question arises how much "existential" information could be obtained from conscious material alone, particularly as the two most thoroughly documented case presentations were those of patients whom Boss had previously treated by the psychoanalytic method.

Lehrbuch der Urologie. Von Prof. Dr. Med. J. Minder, ehem. Ordinarius für Urologie und Direktor der Urolog. Universitäts-Klinik Budapest zur Zeit Spezialarzt der Urologie in Zürich. Sammlung medizinischer Lehr- und Handbücher für Ärzte und Studierende, Band IV. Cloth. Price, \$7.50 Swiss francs. Pp. 348, with 62 illustrations. [Distributed in U. S. A. and Canada by Grune & Stratton, Inc., 381 4th Ave., N. Y. 16.] Hans Huber, den Marktasse 9, Bern, 1946.

This textbook of urology was written for general practitioners and others with little urologic experience. In the midst of the present trend toward textbooks of urology in two or more volumes, the author has succeeded in presenting most of the pertinent urologic facts in one volume.

The text is written clearly and simply. Each chapter is outlined with the aid of marginal notes which facilitate reading. Essential information from the basic sciences is introduced in proper perspective. The illustrations are few and leave something to be desired. The chief criticism that can be directed against the book is the omission of recent advances in urology. Newer knowledge of the bacteriology of infections of the urinary tract and its importance in the treatment of such infections is missing. Chemotherapy in infections of the urinary tract is carried to the sulfonamide era only. This can undoubtedly be accounted for by the author's inability, as a result of the war, to obtain experience with the newer and more powerful chemotherapeutic agents. Perhaps for the same reason, newer knowledge concerning the treatment of cancer of the prostate, both medical and surgical, is also omitted.

La réticolose histiomonocytaire. Par P. Cazal, chef de clinique à la Faculté de médecine de Montpellier, Montpellier. Paper. Price, 350 francs. Pp. 195, with 32 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1946.

While hematology in general suffers from a complexity of terms, designations of conditions involving the reticuloendothelial system are particularly confusing. One can therefore sympathize with the author's effort to bring some semblance of order out of this ill defined group of diseases, but it is doubtful whether his conclusions will be completely accepted by other authorities in this field. In the first part of the monograph he attempts to define his term of *réticolose histiomonocytaire* as a pure malignant metaplastic proliferation of the reticuloendothelial system and does not agree that it should be grouped together with other less specific terms. He uses the terms reticulosis or reticuloendotheliosis generally to designate the specific histologic unit involved—the reticulum or stroma. Cazal is in agreement with Downey in his use of the term leukemic reticuloendotheliosis in referring to a leukemia with a primary, irreversible hyperplasia of the reticuloendothelium (the Schilling type) and differentiates this from most cases of monocytic leukemia (Naegeli type) where the reticulum is not involved. After a short discussion of the history of the subject and a review of the foreign publications since 1929, the author reviews the history of French literature and research in this field. In his discussion of terminology he includes the following conditions under the term *réticolose histiomonocytaire*: Letterer-

Siwe's disease, leukemic reticulosis (Schilling) and atypical forms such as granulomatosis and mesenchymatous sarcoma. He then discusses localization of the disease process and tabulates the organs involved according to clinical observation. Even if the liver and spleen are not enlarged they may show involvement pathologically. The hepatosplenic form does not respond well to roentgen therapy ultimately, while the adenopathic form yields more favorably. The pathologic changes in other organs and tissues are discussed in detail. The blood picture is distinctly variable from a normal blood picture, leukocytosis or leukopenia. Generally the monocytosis is diagnostic and occurs in about 70 per cent of the cases with morphologic changes of large, indented nuclei, often bizarre in appearance, with nucleoli and with the cytoplasm rich in azurophilic granulation. The clinical forms and pathologic picture of the typical disease are next discussed in detail. The author attempts to differentiate some of the etiologic and pathogenetic features of this disease from those in other diseases of a neoplastic nature. The treatment that the author advises is ascorbic acid in high doses, blocking the reticuloendothelial system with congo red, anti-reticulum serum, colchicine and roentgen therapy. In the concluding section of the monograph the author discusses the relation of this disease to agranulocytosis, granulomatosis (Hodgkin's disease, mycosis fungoides and eosinophilic granuloma), Still's disease, lipid storage diseases (with special reference to xanthomatosis) and reticulum cell sarcoma. The bibliography is adequate and contains short abstracts of each of the articles cited. The illustrations are black and white. A working concept of the metaplastic and neoplastic reactions of the reticuloendothelial system would be desirable, but one concludes this monograph with a confused state of mind. Perhaps an adequate amount of information is not available, but some concept might be formulated which would reduce this subject to a more rational basis than in this presentation.

Adjustment to Physical Handicap and Illness: A Survey of the Social Psychology of Physique and Disability. By Roger G. Barker, Beatrice A. Wright and Mollie R. Gonick. Social Science Research Council Bulletin 55. Paper. Price, \$2. Pp. 372, with illustrations. Social Science Research Council, 230 Park Ave., New York 17, 1946.

This work is Bulletin 55 (1946) of the Social Science Research Council. The basic approach is that of the research worker in psychology dealing with behavior manifestations resulting from reactions of the individual to variations of his health and physical structure, both congenital and acquired. The material presented is not without definite value for those who desire assistance in finding appropriate productive employment for the physically impaired.

The presentation begins with reference to factual data and a discussion of behavior reactions attributable to variations of body conformation and function. Parts of this section are technical and use terms and schematic devices which will be difficult for those not conversant with advanced psychology.

"Crippling," forms one of the large subdivisions of this publication and includes all previous pertinent studies. There is a detailed comparative study of the situation reactions of 2 female adults; one having had poliomyelitis in childhood with permanent impairment of the lower extremities, the other with an essentially whole body. Their contacts with reality are covered in a manner which illustrates the sociologic problems presented.

Tuberculosis is subjected to close scrutiny as a modifier of behavior. The concepts and prejudices of society toward the tuberculous person are evaluated.

The material devoted to impaired hearing is a monograph in itself, so complete is the coverage. The discussion proceeds from basic psychologic considerations to the cultural, educational and legal impacts on those deprived of hearing. The long chapter on "Employment of the Disabled" contains much practical information, with studies on employer practices in hiring the physically impaired, occupational records of impaired workers, performance of the physically impaired, earnings and promotions, job stability, job analysis, accident proneness and insurance.

The highlights of this bulletin might be referred to as follows: (1) a voluminous bibliography, (2) systematic arrangements of research summaries, (3) deprecation of the practice of announc-

ing conclusions on the basis of insufficient data and the closely associated pitfall of allowing the isolated unusual or difficult case to color unduly the thinking on the group within which it falls and (4) conclusions and suggestions for new subjects to be investigated.

Elementi di fisiologia e patologia dell'uomo in volo. Di Lo Monaco Croce Tommaso. Presentazione del Prof. R. Margaria. Paper. Price, 300 lire. Pp. 257, with 113 illustrations. Ministero dell'Aeronautica, Stabilimento Fotomeccanico, Roma, 1946.

This well presented and clearly written book is divided into three main sections; the first two deal with the effects of high altitude and acceleration on the organism and the third with the methods, techniques and apparatus employed in the investigation of aeronautical physiology. The substantial amount of data lacks adequate interpretation, leading to the impression that the volume was assembled somewhat hastily. The book is intended both for the physiologist interested in aeronautic problems and for the pilot who wishes to obtain an intelligent understanding of the functional changes that occur in flying. Both the physiologist and the pilot will find profitable the reading of this book, which, however, contains too much physics and too little physiology to be of sound interest to the physiologist and too little mechanics and too much physiology for the average flier.

A Course in Practical Biochemistry for Students of Medicine. By A. T. Cameron, M.A., D.Sc., F.R.I.C., Professor of Biochemistry, Faculty of Medicine, University of Manitoba, Winnipeg and Frank D. White, A.R.T.C., Ph.D., F.R.I.C., Assistant Professor of Biochemistry, Faculty of Medicine, University of Manitoba. Fifth edition. Fabrikoid. Price, \$3.50. Pp. 216, with 23 illustrations. The Macmillan Co., 60 Fifth Ave., New York, 1946.

This textbook is designed to acquaint medical students with the biochemical tests which have a bearing on subsequent medical subjects and the clinical applications of biochemistry. A large number of qualitative and quantitative procedures are presented in a concise, understandable and logical manner. The more complex biochemical procedures are purposely omitted, and quantitative procedures are limited to one approved method.

The book is not intended for use by students specializing in biochemistry and would be unsuitable for such a purpose. There are few alterations and additions to this revision. The textual matter might well have included brief descriptions of some of the new instruments which have come into prominent use in analytic biochemistry.

The Public Welfare Directory 1947. John L. Goetz, editor. [Eighth annual edition.] Fabrikoid. Price, \$1.80. Pp. 307. American Public Welfare Association, 1313 E. 60th St., Chicago 37, [n. d.].

The 1947 Directory, published by the American Public Welfare Association, is limited to agencies that expend public funds for welfare purposes. Uniformity, through use of code, is maintained from the national level through the state level and into counties and cities. The code includes eighteen public welfare services or programs. The agency and person or persons responsible for administration are listed.

As an additional aid to welfare workers the directory includes an explanation of methods to be followed in interstate correspondence concerning welfare clients. To supplement this, an appendix outlines the types of information usually available from the agencies and the conditions under which information will be supplied. A table shows the residence requirements of general assistance programs.

Diagnostic neuro-chirurgical. Par Jean Guillaume et Jean Sigwald. Préface du Professeur Georges Guillaum. Paper. Price, 500 francs. Pp. 457, with 75 illustrations. Presses Universitaires de France, 108 Boulevard Saint-Germain, Paris 6^e, 1947.

A splendid contribution to the rapidly growing neurosurgical literature has been made by these two authors. The book is devoted to the problems of diagnosis and is of special value to the neurosurgeon, since the entire outlook of the authors is primarily neurosurgical. Neuropathology and neurophysiology are thoroughly and interestingly covered, with excellent line drawings plentifully evident. Neurosurgical diagnostic procedures are well described. Regional diagnosis from symptoms is correlated with anatomic location of the injury or disease.

This is a valuable addition to the library of any neurologist or neurosurgeon with a working knowledge of French.

The Influence of Positive Pressure Breathing on the Circulation in Man. By Lars Werkö. Also published as a Supplement to Acta medica Scandinavica. Paper. Pp. 125, with 20 illustrations. Alb. Bonniers Boktryckeri, Stockholm, 1947.

This monograph reports a detailed investigation of three types of positive pressure breathing. The final recommendation "when positive pressure breathing is used for artificial respiration, the inspiratory period with high pressure should be short and the expiratory period should be long, with expiratory mean mask pressure as near atmospheric as possible" is supported by impressive observations of cardiac output and other hemodynamic variables. The monograph is recommended to all those who have occasion for positive pressure therapy, notably to anesthesiologists and those concerned with respirator design.

Medicine in the Changing Order: Report of the New York Academy of Medicine Committee on Medicine and the Changing Order. Cloth. Price, \$2. Pp. 240. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Square, London, E. C. 1, 1947.

Four years ago the New York Academy of Medicine formed the Committee on Medicine and the Changing Order to study the economic and social changes taking place in medical care. The forty-eight members of this committee have examined critically every phase of the current medical situation and have published the results in ten separate volumes, each dealing with a special subject.

In this report the committee attempts to draw together its findings and present its conclusions as to what may best be done to remedy present inadequacies. The committee has recognized the futility of viewing medical care as an isolated phenomenon and has made an effort to present it as a part of the whole pattern of present day living.

The book is suitable for study groups of organizations and particularly for the woman's auxiliaries of the various medical societies.

Methods of Diagnosis. By Logan Clendening, M.D., F.A.C.P., and Edward H. Hashinger, M.D., F.A.C.P., Professor of Clinical Medicine, University of Kansas School of Medicine, Kansas City. Cloth. Price, \$12.50. Pp. 868, with 143 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

In this remarkable book, chapters 1 and 2, called Principia Diagnostica, deal with a subject not found in any other modern book. Ordinarily the subject of logic and diagnosis is acquired by the student in ward work in a rather haphazard fashion. By some it is not acquired after a lifetime of practice. Instruction in this subject should be helpful to the intelligent student. The book covers practically the entire field of diagnosis in the realms of medicine and surgery and is replete with stimulating quotations and references to original work. The semicolloquial style of writing will appeal to most students. By and large the book, with its homely line drawings and photographs, is worth the reading for any student of medicine.

Chronic Disease and Psychological Invalidism: A Psychosomatic Study. By Jurgen Ruesch, M.D. In collaboration with Robert E. Harris, Ph.D., and others. With a foreword by Karl M. Bowman, M.D. From the Division of Psychiatry, University of California Medical School and the Langley Porter Clinic, San Francisco. Psychosomatic Medicine Monographs. Published with the Sponsorship of The American Society for Research in Psychosomatic Problems. Paper. Price, \$3. Pp. 191. Psychosomatic Medicine, 714 Madison Ave., New York 21, 1946.

This monograph deals with the psychologic factors that prolong convalescence following a chronic disease. The material is well documented and objective. All practitioners are at some time confronted by the problems of delayed convalescence without apparent organic basis.

Hallux valgus. Por Carlos Khoury. Tesis de doctorado, Universidad nacional de Buenos Aires, Facultad de ciencias médicas, Escuela de medicina. Paper. Pp. 227, with 91 illustrations. Buenos Aires, 1946.

This Spanish work presents its material in good sequence. The bibliography is extensive but rather superfluous. The detailed table of 126 cases is superfluous. The author describes and illustrates various operations such as the Schede, Silver, Stein, Keller, Hueter, Mayo, Girdlestone, Lapidus, Hawkins and McBride. The publication would be more useful if he told which operations were best and why and sustained his opinion with case reports.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

ATOMIC ENERGY AS A THERAPEUTIC AGENT

To the Editor:—I should like information on the substances developed from atomic energy that are useful in the treatment of Hodgkin's disease.

Oscar A. Kafer, M.D., New Bern, N. C.

ANSWER.—The press has overemphasized the present importance of "atomic energy" as a therapeutic agent for neoplastic diseases. There is no substance developed from atomic energy which has proved of special benefit in the treatment of Hodgkin's disease. In the past radioactive phosphorus has been employed, but the results have not been superior to, or possibly equal to, those attained by the use of roentgen ray therapy for this condition. If atomic energy is to be employed for the development of a therapeutic measure for Hodgkin's disease, it will be in the form of some radioactive material that will show a decided predilection for concentration in the lymphatic tissue. Since extensive trial has shown that irradiation is at best a palliative measure, although sometimes effective, the therapy which might be expected from atomic energy will be some form of radiation and therefore will be essentially of a palliative nature.

ARACHNOIDITIS WITH TUBERCULOSIS

To the Editor:—A man aged 38 was first treated for right unilateral pulmonary tuberculosis in 1933. In 1941 he was found to have an extensive tuberculous infection of the right chest wall, including two upper ribs and mixed empyema. Thoracotomy was followed by four stages of thoracoplasty, the last being a modified Schede operation which uncapped the remaining empyema cavity in January 1944. In December 1943 pain over the thoracic portion of the spine and radiating around the right side of the chest, slight subjective numbness of the lower part of the body and slight sphincter weakness were reported. The symptoms remained essentially unchanged until April 1944, when there developed complete paralysis of the lower half of the body, with loss of sensation. Laminectomy confirmed the diagnosis of extensive adhesive arachnoiditis. Within a year partial control of the bladder and rectal sphincters returned, along with enough voluntary control of the legs to permit self care in bed. More recently the patient has been able to get into a wheel chair and propel himself without aid. Examination at present reveals three draining sinuses in the right chest wall, one being about 3 inches (8 cm.) from the spine. There is decided spasticity and weakness of both legs, with occasional clonic spasms. Abdominal reflexes are absent, lower tendon reflexes bilaterally increased. There is a bilaterally positive Babinski sign, with ankle clonus. Sensory examination reveals hyperalgesia of the legs except for a small area of anesthesia on the left ankle. There is usually no urinary retention. The weight is well maintained. Physiotherapy has not been attempted because of continuing mixed infection in the chest wall. The debility and the severity of the neurologic symptoms vary with drainage. Is the danger of a return of the extreme spinal disability great enough to contraindicate treatment of draining sinuses by surgical intervention with or without streptomycin? If so, what treatment, if any, should be given?

Amelia G. Wood, M.D., Richmond, Va.

ANSWER.—If debility and the severity of the neurologic symptoms increase with decrease in drainage from the sinuses, the patient's prognosis should be improved if constant good drainage can be established. One of the sinuses may be directly connected with the intraspinal lesion or indirectly connected with it through a residual empyema cavity or cleft. If there is any doubt about there being free dependent drainage from the empyema or any extension of it, such drainage should be first established; this might indirectly drain the sinuses from within. If the condition of the sinuses were unimproved a month or two later, surgical exploration of the sinus nearest the spine, or perhaps all the sinuses, should be made in an effort to find poorly drained abscesses. If preoperative injection of the sinuses with iodized oil (followed by stereoscopic roentgenograms and a flat lateral film) need to be done, the injection should be carried on only at an exceedingly low pressure. In view of the general situation, extensive incisions and resection of extensive areas of tuberculous osteomyelitic regenerated ribs would probably be unwise. Streptomycin might be useful at the time of the sinus operation and afterward, especially if abscesses were found and were well drained. The suggested surgical treatment is more likely to prevent the condition of the spinal cord from becoming worse than to make it worse.

LIVEDO RACEMOSA OR RETICULARIS

To the Editor:—A female 21 months of age was first seen at 5 weeks of age for purplish discoloration of the skin of the right arm and both legs. The mother's pregnancy was normal. The delivery was uneventful except for a fractured right clavicle subsequently discovered in the baby. The family history is irrelevant. The general health of the baby is excellent. From delivery on there has been a violaceous, mottled, somewhat unsightly discoloration of the skin over the arms and the right leg, confined mostly to the dorsal aspects of the forearms and thigh down to and including the knees. The discoloration is a network of purple lines apparently following the distribution of the superficial veins. There has never been swelling, edema or any phenomenon commonly associated with circulatory obstruction of the extremities. The only improvement noted since birth has been that due to normal growth changes. Warmth exaggerates the appearance of the discolored areas, as does exposure to extreme cold. Tanning this summer improved the appearance a little. A tourniquet above the areas increases the discoloration. My original impression was that the child had a congenital abnormality of the superficial veins of the involved areas. What is the diagnosis? The possibilities of treatment? The best course to advise the parents to pursue?

J. M. Albergotti Jr., M.D., Orangeburg, S. C.

ANSWER.—The inquirer does not tell the condition of the subcutaneous fat or of the skin itself, other than the latter's discoloration. In certain atrophies of the skin the venous network becomes more visible and conspicuous. Since no mention is made of such atrophy, it is taken for granted that there is none.

This infant's condition would seem to be best classified under the heading of livedo racemosa or reticularis. According to Becker and Obermayer, these conditions resemble cutis marmorata but are more extensive and more permanent. They may or may not be associated with organic changes in the superficial vessels. From the clinical point of view, livedo reticularis is a more permanent, severer livedo occupying diffusely the areas ordinarily involved in cutis marmorata. Livedo racemosa, on the other hand, is less extensive. Eruptions consist essentially of bluish red, tree-shaped or netlike, for the most part elevated elements from 1 to 2 cm. wide. The color is most intense in the center and fades out toward the periphery. The lesions feel cool to the touch and are uninfluenced by changes in temperature.

In cutis marmorata prolonged application of heat or cold results in an exaggerated expansion of the blood vessels. Livedo racemosa is not associated with obliterative vascular changes. Stroking the skin is followed by prolonged blanching, and the vascular pattern returns with a brilliant hue. These disorders have been reported in association with both organic and functional changes. It is said that the functional forms may be associated with endocrine and toxic disturbances; the organic changes underlying some of these disorders are said to be syphilis, tuberculosis, arteriosclerosis and chronic endocarditis, as well as periarteritis nodosa.

In this infant it would seem best to classify this disorder as a nevusoid one, because the disturbance has been present since birth. The great probability is, of course, that no organic changes have intervened so early in life.

Treatment is unsatisfactory. If any organic disturbance should be found serving as a basis, therapy should be directed toward it.

PREGNANCY FOLLOWING CANCER OF CECUM

To the Editor:—A woman aged 33 had a grade 3 carcinoma of the cecum, which was surgically removed sixteen months ago. Up to this time there is no evidence of recurrence or metastasis. She is now two months pregnant. Is there any danger in permitting her to continue with the pregnancy? She has two children and does not wish to take any unnecessary risks.

M.D., Wisconsin.

ANSWER.—In animal experiments it has been proved conclusively that estrogens are carcinogenic. In human beings, however, the few cases in which there was a presumable relation between excessive estrogen administration and the appearance of cancer are not sufficient on which to base scientific judgment. During the reproductive age of a woman there is a considerable amount of estrogen in the body. Because of the possible stimulating effect of estrogen on carcinoma of the breast there is now a growing tendency to castrate all women in the premenopausal age who are operated on for carcinoma of the breast. The castration may be brought about by radiation therapy but better still by surgical removal of both ovaries. The results appear to be better in the women who are castrated after radical mastectomy than in those who are not castrated. The abolition of ovarian function not only destroys the production of estrogens at their chief source, the ovaries, but also prevents pregnancy, during which large amounts of estrogens circulate in the blood. If pregnancy occurs in a woman who has had a breast removed for cancer, or in one who has metastases following radical mastectomy, there is a possibility that the estrogens produced

during the gestation may reactivate the cancer or aggravate the metastases. That is why pregnancy is contraindicated after a radical mastectomy, and also why the use of estrogens is contraindicated for menopausal symptoms in women who have had cancer of the breast. (Strangely enough, in older women estrogens relieve the pain associated with metastases.)

Not many believe that the estrogens in pregnancy have deleterious effects on cancer other than carcinoma of the breast. However, J. A. Schockaert (*Bruxelles-méd.* 15:1010 [July 14] 1935) is of the opinion that all women presenting a cancer should be castrated regardless of the location of the cancer.

Presumably in the case in question there is little if any risk of recurrence of the cancer due to the pregnancy. However, in view of the fact that there is still a possibility of return of the cancer regardless of pregnancy, and the fact that the woman has two living children, a physician probably would not be criticized for terminating the pregnancy.

MULTIPLE SPONTANEOUS ABORTIONS

To the Editor:—A woman physician (American) had two normal pregnancies with normal full term healthy infants in 1938 and 1940. In the past four years five spontaneous abortions have occurred from the fourth to the tenth weeks of gestation, with the exception of the fourth, which was a missed abortion with the fetus which died at about the fourth month expelled two months later. The general state of health is excellent. Pelvic examination has always revealed normal conditions. Menses between pregnancies are normal. The Rh factor is positive; endometrial biopsy revealed nothing abnormal. The basal metabolic rate varies from minus 19 to minus 28 per cent. Thyroid extract has been given during the last three pregnancies, 2 grains (0.13 Gm.) a day, larger doses causing loss of weight below normal for patient. Progesterone, "ephynal acetate" (alphatocopherol acetate) and vitamin B complex have been given during each pregnancy in the usual doses. Mild secondary anemia has been controlled with iron preparation. During the last pregnancy estrogen was added in the form of "progyon B," 10,000 international units three times a week. Activity has been restricted during the last two pregnancies but strict rest in bed has not been enforced. Have any diagnostic factors been overlooked? The patient's present age is 40. Is another trial advisable? What should be the therapeutic program if pregnancy does take place?

M.D., China.

ANSWER.—It is not stated whether this woman had her two full term living children in the United States or in China. Not infrequently American women who move to China have menstrual irregularities and spontaneous abortions. In the case cited in the query, the studies made between pregnancies and the treatment carried out during the gestations have been ample. Considering that the patient will be at least 41 years old if she gives birth to another child, that she has already been pregnant seven times and has two living children, it is not advisable for her to become pregnant again. However, should pregnancy occur, the only addition to the therapy should be large doses of estrogen in the form of 10 to 15 mg. of diethylstilbestrol by mouth every day and complete rest in bed, although the latter is not important after the fourth month.

SWELLING OF THE PAROTID GLAND

To the Editor:—A man aged 23 has the following history and physical findings: Four or five days before coming to me he had the upper and lower three molars of the right side extracted. He had no reaction on that side. He returned to the dentist two or three days later because of external swelling of the left side of the face and neck and was referred to me after dental x-rays did not reveal any pathologic changes on that side. He seemed to have an early case of mumps. Two days later he returned with what seemed to be a clear case of mumps involving the left parotid gland. In addition there was a swelling about the size of my hand in breadth overlying the manubrium. This did not seem to be connected with any structure in the neck. It was tender and had the same feel on palpation that the swollen parotid gland had. It was not red and was assumed to be some aberrant gland which was involved by the same process. There was no elevation of temperature. I should appreciate an explanation of just what this was and its significance, if any.

M.D., Kentucky.

ANSWER.—There are at least two possibilities to consider. First, the question of trauma during the operation. Was the patient's head held in such a position that pressure was exerted on the left side of the face when the teeth were extracted from the opposite side of the mouth? Is it possible that there were infected molars on the left side at the time the teeth were extracted?

The condition described was not likely due to mumps. In severe cases of mumps with bilateral involvement the swelling is sometimes continuous from the parotid glands downward and may overlap the manubrium. However, in two large contagious disease hospitals during a period of many years nothing of the kind has ever been observed in mumps when there was only unilateral involvement. Moreover, the fact that the swelling

overlapping the manubrium in this case was separate and distinct from that which involved the parotid is further reason for not favoring a diagnosis of mumps. It would be interesting to know whether there was a past history of this disease.

It is difficult to dismiss the possibility of trauma as a cause for the condition described. If a white blood count was made and a decided leukocytosis was present, such an observation would be opposed to a diagnosis of mumps. From an explanation of the swelling at the base of the neck, thought may be given to some of the uncommon cystic formations.

PRECAUTIONS BEFORE GOING TO AFRICA

To the Editor:—A man expects to leave for French Equatorial Africa to do construction work. What precautions should be taken as regards immunizations, malaria prevention and the like? He would also like to know what type of clothes to wear and what type of mosquito repellent to use. Any further pertinent information will be greatly appreciated.

J. K. Bembenista, M.D., Buffalo.

ANSWER.—Any one who expects to reside in French Equatorial Africa should be immunized against yellow fever, smallpox and typhoid fever. With regard to the prevention of malaria, it is still necessary in that country to sleep under bed nets from dusk to dawn and avoid going from behind screened quarters any time during this period while actually not in bed. Any of the standard Army or Navy repellents which are available on the open market today are extremely useful compounds.

If the area is especially noted for its incidence of malaria, it would be well to take one tablet of chloroquine biweekly (manufactured under the trade name of "aralen diphosphate"). This drug has been found highly satisfactory in suppressing malaria due to *Plasmodium vivax* and preventing the occurrence of that due to *Plasmodium falciparum*, the most predominate type in West Africa.

DISABLING BLEEDING AFTER OOPHORECTOMY

To the Editor:—A bilateral oophorectomy was performed on a multipara aged 31 because of extensive pelvic endometrial transplants. A "negative" dilation and curettage preceded the operation. For six months after operation she had amenorrhea and minimal menopausal symptoms requiring no treatment. She was completely relieved of pelvic pain and painful defecation. Now she is having extremely profuse menstrual (?) periods occurring every four to five weeks and lasting five to ten days. The amount of blood lost is disabling. Assuming that the oophorectomy was complete, what is the origin of the bleeding and what should be done about it? Pelvic examination reveals normal conditions at present.

M.D., New Jersey.

ANSWER.—There are several possible sources of bleeding in this case. First, perhaps some ovarian tissue was left behind and this began to function abnormally. Second, estrogen production may have started or increased from some other source in the body, most likely the adrenal glands. Third, in spite of the patient's age she may have a cancer of the endometrium. Fourth, the pituitary gland may be a factor in the uterine bleeding in this case. It is assumed that the patient has not been taking estrogens, because it is specifically stated that she had "minimal menopausal symptoms requiring no treatment." As is well known, estrogens can and often do bring uterine bleeding long after natural or artificial menopause. Because the amount of blood lost is disabling, and assuming that the patient has not taken estrogens, a hysterectomy should be performed. This should be carried out abdominally because the previous operation revealed extensive endometrial transplants and also because any ovarian tissue which may have been left behind must be removed. The uterus should be opened during operation; if carcinoma is present radiation therapy will have to be started soon after operation. Of course, a histologic examination should be made of all tissue removed.

TREATMENT OF SCLERODERMA

To the Editor:—What are the indications for starting treatment with dihydrotachysterol when a patient has scleroderma?

Ben Raney, M.D., Linton, Ind.

ANSWER.—Many physicians are skeptical about the value of a specific treatment for scleroderma, particularly for generalized progressive scleroderma, to which this query presumably refers. The drugs usually used are vasodilators, such as prostigmine or histamine and bismuth and thyroid substance, in addition to supportive measures. Because some cases of generalized scleroderma appear to be linked to parathyroid dysfunction, the use of dihydrotachysterol is suggested. Bernstein and Goldberger (*THE JOURNAL*, March 2, 1946, p. 570) reported on its successful use in a patient in whom scleroderma developed after thyroid-

ectomy. Other physicians fail to notice benefit from the use of dihydrotachysterol, and they suggest that the favorable results occur in cases of scleroderma-like changes which may appear as sequelae to vascular disease. The use of dihydrotachysterol would seem to be justified in a disease for which there is no other specific treatment. One must be cautious and check the blood periodically for excess of calcium during the administration of this drug. Recently (abstracted, *THE JOURNAL*, September 27, p. 252) there was a report of a favorable response from treatment with "promin" in several cases of scleroderma from which an organism thought to be a mycobacterium was recovered.

SUPRACONDYLAR FRACTURES

To the Editor:—In the treatment of patients with supracondylar fractures of the humerus some authors recommend supination of the forearm in applying the cast after reduction. What is the acceptable position after reduction?

Michael F. Volpe, M.D., Brooklyn, N. Y.

ANSWER.—Supination of the forearm is the desired position after reduction of supracondylar fracture of the humerus in applying a plaster splint.

The act of reduction involves traction on the forearm and slight overextension at site of fracture during this traction, followed by flexion, still maintaining traction, to bring the long axis of the forearm directly over that of the arm. Therefore the forearm is handled better in supination and this position puts an equal pull on the lateral ligaments of the elbow joint, which in the usual case are not torn and still have attachment to and pull on the small displaced distal fragment of the humerus. This, backed by pressure of the triceps tendon behind, insures reduction. If the elbow joint is held in flexion during the healing, as it is in the average instance, it may stiffen a little temporarily. Supination is much to be preferred even with slight stiffening because that position of the forearm is the most difficult to regain and is the most useful for function.

SPRAYING THE NOSE WITH BORIC ACID

To the Editor:—Will the daily spraying or insufflation with powdered boric acid be harmful to the tissues and mucous membrane of the nasal passages and sinuses?

M.D., Texas.

ANSWER.—The daily spraying or insufflation with powdered boric acid is likely to interfere with the important function of the cilia and mucous blanket. This is a self regulating mechanism and is highly efficient.

Any foreign particle on the nasal and sinus mucous membrane is swept along by the cilia and is ultimately eliminated through any given sinus ostium or (if already in the nasal fossa) down the nasopharynx, or it may be blown out through the anterior nares.

There would be no point in spraying or insufflating boric acid powder, since the nose is a self cleansing mechanism and contains all the necessary structures with which to protect the deeper tissues from becoming more easily involved in any given infection.

MORPHINE ADDICTION

To the Editor:—1. Can morphine addiction simulate organic pain so closely that the patient is addicted to morphine but sincerely and honestly does not know it? 2. Can meperidine hydrochloride ("demerol hydrochloride" N.N.R.) do this same thing as morphine? M.D., New York.

ANSWER.—A person using morphine to the point of physical dependence has pain when the dosage is discontinued or drastically reduced. If there is also some preexisting source of pain, this will of course be severer. The questioner presumably uses the word "addicted" in the sense of "having physical dependence." If he does, one occasionally encounters addicts who know nothing about physical dependence; if they have never been withdrawn from morphine they may not understand the significance of the pains and other manifestations of this syndrome. The use of morphine does not produce pain; its withdrawal does.

The situation as to "demerol" is somewhat similar; its abstinence syndrome, however, is not as severe as that of morphine.

Addicts, in an attempt to obtain morphine, may "simulate" pain. This has also been found among nonaddicts. In the case of an addict with definite withdrawal manifestations, too great a tendency to assume that he is simulating may result in a fatality.

CARBONATED BEVERAGES

To the Editor:—I would like to know something of the composition of the drink variously known by such names as "soda water," "seltzer," "club soda" and "charged water." Are those which are made artificially a simple solution of carbonic acid and water? Are there electrolytes such as sodium or potassium in the solution? Is there any variation in composition? Are the various carbonated beverages, such as gingerale, merely an addition of a syrup to such a solution?

M.D., New York.

ANSWER.—Charged water, club soda, seltzer, soda water and sparkling water are names designating carbonated water which, when iced, is suitable for consumption. Most of such carbonated waters are prepared from filtered water by the addition of carbon dioxide. No attempt is usually made to provide a particular mineral content. Some manufacturers use distilled water to which a small amount of alkaline buffer is added prior to carbonation. The mineral content of carbonated waters varies somewhat with the source of the potable water employed in their manufacture, but the salts present are generally considered to be insignificant in contrast to the so-called "mineral waters." The usual carbonated beverage consists of a carbonated water to which sugar and a suitable, palatable flavor is added.

TREATMENT OF STATUS ASTHMATICUS

To the Editor:—In *Queries and Minor Notes* of September 27, page 259, discussion on the treatment of status asthmaticus appears in which the author warns against the use of morphine and meperidine as well. The statement is made: "Meperidine has a similar action (referring to morphine) and, until experience with its use is much greater than it is at present, it should not be used in severe asthma." I agree with the warning against morphine, but believe that the effects of ordinary doses of meperidine on the respiration are negligible and that unless used in conjunction with sedative doses of the barbiturates, significant depression of the respiration in bronchial asthma does not take place. When a patient is refractory to aminophylline, the need for other drugs that produce bronchial relaxation is a real one. Of these, the most useful appears to be meperidine administered in dosages of 30 to 75 mg. at six or eight hour intervals for a period of four to six days. The drug should not be used in combination with heavy doses of barbiturates, as all of them in excessive amounts depress the respiration. The danger of addiction should be recognized but not overemphasized. (Barach, A. L.: *Physiological and Antibiotic Therapy of Bronchial Asthma*, Conn. State Med. J. 11: 819, (1947). References which concern the view expressed are listed: Grollman, A. and Slaughter, D.: *The Pharmacology and Therapeutics*, Philadelphia, Lea & Febiger, 1947, p. 369; Batterman, R. C. and Mulholland, J. H.: *Arch. Surg.* 46: 404 (March) 1943; Curry, J. J.: *M. Clin. North America*, 30: 1138 (Sept.) 1946; Glaser, J.: *Am. Pract.* 1: 185 (Dec.) 1946; Gottschalk, R. H.: *Am. J. Obst. & Gynec.* 52: 651 (Oct.) 1946, and Taylor, E. S.: *Northwest. Med.* 45: 740 (Oct.) 1946.

Alvan L. Barach, M.D., New York.

To the Editor:—To the answer concerning the treatment of status asthmaticus in *The Journal*, September 27, page 259, the following additions and changes are indicated according to my experience. Immediate consideration of the possible specific causes, so necessary in every case, was not mentioned. Symptomatic treatment is increasingly effective as the causes of the asthma are controlled. My experience stresses the frequency of food and inhalant allergy and the rarity of drug and especially bacterial allergies and so-called intrinsic asthma.

Food allergy must be assumed in all cases of bronchial asthma which obviously are not due to seasonal pollen allergy or to some obvious animal emanation or other inhalant allergy. To study and control possible allergy to food, diet trial is usually necessary because of the well recognized fallibility of the skin test in this type of sensitization. For such trial my cereal-free elimination diet (Rowe, A. H.: *Elimination Diets and the Patient's Allergies*, Philadelphia, Lea & Febiger, 1944) has proved of increasing value. Until appetite returns the food in the diet can be served in a liquid, soft or pureed form. If vomiting is present 5 per cent dextrose in isotonic sodium chloride solution or water, as indicated by sodium chloride and fluid requirements, must be given by vein.

To consider inhalant allergy the patient should be in an environmentally controlled hospital room or in one similarly prepared at home. If allergy to pollen or air dust is suspected, a pollen filter should be in the window. If oxygen is required the air and oxygen in the tent are relatively free of pollen and dust, especially if dustproof covers are on the pillows and mattress.

The symptomatic control should use epinephrine in 1:1,000 dilution hypodermically. If it is not effective aminophylline by vein, every six to twelve hours, should be given. Iodides by mouth may be helpful. Intravenous fluids and oxygen must be given when required. Opium and sedatives are contraindicated in all cases. When death occurs in patients with bronchial asthma, they have usually received a sedative and adequate early attention has not been given to the control of the probable causes.

Epinephrine in 1:100 dilution by inhalation, ephedrine and aminophylline by mouth, and less frequently diphenhydramine ("benadryl") or triphenylamine ("pyribenzamine") by mouth, help moderate symptoms after the intractable state has been relieved.

Finally, it is important to realize that food and inhalant allergens remain in the body for days and in decreasing numbers for longer periods, necessitating the continued use of the elimination diet and residence in allergen-free environment, at times for five to fourteen days before definite evidence of improvement occurs.

CERVICAL CYTOLOGY IN DIAGNOSIS OF EARLY CANCER

J. ERNEST AYRE, M.D.
Montreal, Canada

Study of exfoliated squamous cells from the uterine tract in health and in disease opens up weirdly fascinating and provocative avenues of approach to cancer research.

It seems important at the outset to differentiate between the "diagnosis of early cervical cancer" and the term "early diagnosis of clinical, cervical cancer." There is evidence tending to prove that early cancer is a microscopic and preclinical entity, whereas one usually thinks of cervical cancer as a clinical entity. Early clinical cancer is a rare finding. It is most seldom that one sees such a thing in gynecologic practice, and there seems to be a big gap between the so-called normal cervix and clinical, cervical carcinoma, which is still such a formidable disease.

The detection of cells with atypical nuclear structure scraped from clinically normal cervixes leads to the belief that even though the epithelial surface may be intact, metabolic changes are taking place in the cell in association with the development of nuclear structure characteristic of cancerous growth. Such a lesion may not become clinically apparent until some acceleration of growth accompanies invasiveness, ulceration develops and clinical carcinoma appears.

The early stage of cervical cancer, then, is rare chiefly because of its insidious character, because it does not declare itself by producing symptoms, because the lesion is invisible and because the disease is a pre-clinical, microscopic entity at this stage.

How large must a cancer be before it may be diagnosed as such? Most clinical cancer is not early, even though it may be small, and so long as one has to depend on visual recognition for diagnosis, treatment is going to meet the same frustration as at present.

What constitutes early cancer? Modern theories indicate that early cancer represents specific changes in cell metabolism, cell behavior and cell structure.

Medical science has not yet provided the means of detecting a metabolic change indicating cancer, and the basic method of diagnosing cancer has been through the recognition of morphologic changes in tissue biopsies. These changes have constituted, first, morphologic and nuclear changes of a specific character and, second, invasiveness. Through a study of these two

phenomena the pathologist has been able to predict with great accuracy the subsequent behavior of a cell or a lesion.

In recent years, Papanicolaou's¹ important discovery of cancer cells in the vaginal secretions has focused attention on the structure of the individual cell as a method of detecting cancer. While cytologic methods lack the ability of assessing invasiveness, an abundance of scientific evidence is accumulating, through the work of Papanicolaou,¹ Meigs and Graham,² Jones,³ Warren,⁴ Seibels⁵ and others, to prove that recognition of specific morphologic cell changes enables detection of cancer.

Routine cytologic tests on all our patients have given interesting results. Careful searching of the squamocolumnar junction by serial sections in cervixes desquamating cells of abnormal structure is leading to the diagnosis of minute preinvasive lesions. The detection of altered cell structure in such lesions enables a prognostication that they will ultimately become invasive and malignant if untreated, but they may be removed surgically with excellent chances for cure during the early stage. While not all authorities are in agreement that such nests of cells constitute an inevitable premalignant state, a great deal of evidence is being tabulated which tends to bear this out. TeLinde⁶ has collected a large group of cases showing preinvasive carcinoma in some of whom he was able to demonstrate an interval of several years before invasion occurred. He pointed out that "in none of these women was a diagnosis of cancer possible during the early stage from palpation or inspection of the cervix." Schiller,⁷ Taylor and Guyer,⁸ Knight⁹ and others have similarly reported cases in which a considerable period was known to have elapsed before clinical carcinoma developed.

Pund and Auerbach¹⁰ found 47 cases of preinvasive carcinoma in serial sections from the external os of 1,200 surgically removed cervixes. The chief symptoms were referable to other noncancerous pelvic disease. Only 28 per cent of patients had a history of intermenstrual bleeding. Gross examination of the

cervixes showed in no case any evidence of carcinoma. Microscopically the neoplasms were located near or at the junction of the squamous and columnar epithelium. Such statistics indicate that many early cancers are being missed in routine examination.

It is proposed in this study to deal chiefly with squamous cancer of the cervix, the common malignant offender. This type of cancer arises from a known localized focus, the squamocolumnar junction, according to such recognized authorities as Novak,¹¹ TeLinde and Schiller.

While the apparent invisibility of an early cancer lesion at this location undoubtedly contributes to the present persisting high mortality rate in this type of cancer, the application of cytologic methods should render this type of cancer more amenable to treatment. While a proper biopsy demands a visual lesion for localization, a cytologic test does not.

It has been amply demonstrated by the independent work of numerous investigators in a total of over 40,000 cases that on the positive side of the picture the finding of cancer cells in cytologic smears is accurate to more

cancers which were missed by cervical technics. Therefore, it would appear that selective technics and the method of scraping areas of suspicion contribute to accuracy in diagnosis and in most cases may be relied on to indicate the absence of squamous carcinoma.

A study of the various cytologic methods (the figure) may give some indication of the degree of accuracy to be expected with the different methods. It has been my conviction that while the great facility of taking the test with the vaginal smear method is advantageous, greater time is required to locate the cancer cells. The cellular material is diluted, requiring painstaking study for diagnosis. Further, if improperly taken, the vaginal pool may be missed entirely. The vaginal smear properly taken from the posterior fornix will supply cells from all parts of the uterine tract. Co-workers and I have often found that the smear has been taken from just inside the introitus or from the roof of the vagina (see insert in the diagram of vaginal smear) rather than from the posterior fornix pool. In such cases, early lesions have been missed.

VARIOUS CYTOLOGIC METHODS (THE FIGURE)

1. *The Vaginal Smear.*—The vaginal smear taken from the vaginal pool of secretions in the posterior fornix gives an over-all picture of cells desquamated from the entire uterine tract: cells desquamated from the vagina, cervix, endometrium, occasionally from the tube and rarely from the ovary or abdominal cavity. The chief advantage of this method is the ease with which the test may be taken. Its chief limitations are: (a) Cells from an early microscopic lesion may be missed in the profuse diluted vaginal desquamata. (b) Long, painstaking study is essential for accurate interpretation. (c) A negative result cannot be relied on to indicate freedom from malignant uterine disease. (d) The finding of isolated malignant cells may present a problem in the localization of origin of these cells. This uncertainty may lead to radical surgical treatment. The insert in the figure shows a vaginal smear being taken from the roof of vagina, missing the vaginal pool.

2. *Endocervical Smear.*—The endocervical smear is advantageous in the search for a lesion in the cervical canal, and it is selective to the epithelium lining the canal. It is important to differentiate between the endocervical and the external os cervical smear. A word of caution is given in the use of this method as a "cervical smear." The cannula introduced into the cervical canal may bypass an early squamous cancer developing at the cervical portal (95 per cent) in the search for adenocarcinoma of the canal (5 per cent). Aspiration applied through the cannula, once it is in situ in the canal, will suck up cervical mucus and more of the cervical columnar cells than other cytologic methods. But it does not collect the squamous cells exfoliating at the external os in which the common cancer may be developing.

3. *Endometrial Smear.*—The endometrial smear is valuable in detecting body cancers, which constitute the largest group given a false negative diagnosis. This method must be considered a selective smear of the endometrial epithelium. Its chief advantage is: it gives a more accurate interpretation of adenocarcinoma developing in the endometrium. Its chief disadvantage is that it is not so simply obtained. It is not recommended for routine use. It is strongly recommended, however, as a secondary procedure when vaginal or cervical smears provide endometrial cells which are suspicious but indefinite.

Diagrammatic representation of various cytologic methods.

than 90 per cent in the detection of a malignant growth. There has been some doubt expressed, however, as to the value of a negative result as an indication of freedom from such disease. From an analysis of our first 3,706 cases studied for a diagnosis of cancer, the average error was 3.42 per cent. The majority of the errors made involved false positive smears. Such cases should not be regarded, however, as having produced any harmful effect, other than to require careful investigation and a cervical biopsy. On the other hand, it is a more important consideration if in the presence of a cancer a false negative smear lulls one into a sense of false security and delays the diagnosis and treatment. In our own series of 304 cancers, 5.9 per cent were missed and were near misses (suspicious only), but almost 90 per cent of them were fundal carcinomas. In other words, in cervical cancers by the use of selective methods, the common lesion was missed extremely infrequently (less than 1 per cent), even when these lesions were early and minute in size. It is my feeling that the endometrial smear, which must be considered selective to the endometrial epithelium, would have brought success in detecting those body

11. Novak, E.: Pseudomalignant and Precancerous Lesions of the Cervix, J. A. M. A. 108:1145-1151 (April 3) 1937.

4. *Smear from the Cervical External Os.*—The smear from the cervical external os is offered as an alternative to the vaginal smear. It gives the same over-all cytologic picture as the latter with the exception of the vaginal cells and secretions. Its chief advantage is that a greater concentration of cervical squamous cells are collected for interpretation of cervical carcinoma of the common type (95 per cent). This eliminates more loss of time and increases accuracy of interpretation. Its chief disadvantage is that a speculum must be used to permit the taking of the test.

5. *The Selective Scraping Method.*—The selective scraping method is midway between an aspiration smear and a biopsy. By scraping the circumference of the squamocolumnar junction of the cervix, a true "surface biopsy" of these cells may be collected prior to their actual exfoliation. All other cytologic methods except the biopsy collect cells which have already been exfoliated. The cervical scraping cannot be relied on to give an interpretation of a possible lesion in the body of the uterus. Therefore, it is recommended that the smear from the cervical external os be always taken along with the scraping in routine diagnostic practice. In the presence of a large erosion (as in the insert) the squamous epithelial margin must be scraped in its entire circumference under direct vision. The selective scraping method is, in my opinion, the method of choice for identification of early microscopic squamous cancer of the cervix.

6. *The Cervical Biopsy.*—The cervical biopsy is most selective of all the cytologic methods, as a definite segment of tissue is excised, carrying with it a large aggregation of the cells from that area. In the presence of early cancer, however, a cervical biopsy has its limitations, too. A single biopsy, depending on a visually demonstrable lesion for localization, may miss a small microscopic growth. Multiple sections through the entire circumference of the squamocolumnar junction may be required to provide the true pathologic evidence in early cancer.

COMMENT

For several years my associates and I have taken vaginal smears and smears from the external cervical os as a routine. Almost invariably, a greater concentration of neoplastic¹² cells have been found in the aspiration from the cervical os. Recently, during the past eighteen months, we have used the selective cervical scraping method in the search for early carcinoma. The greater sensitivity¹³ of this method over other cytologic technics is suggested by our results. Fifteen early cervical cancers were diagnosed using the spatula, while vaginal smears taken at the same time failed to show the cells. It would appear, then, that while vaginal and cervical smears will detect an abundance of cells in the presence of a "full blown" cancer, the selective scraping is superior in the detection of microscopic cancer developing at the squamocolumnar junction. It is our feeling that since squamous cancer of the cervix makes up 80 to 90 per cent of uterine cancer, routine methods of practice should be concentrated on early detection of this common offender. Our efforts should be directed toward applying to best advantage the most effective method of diagnosing early curable cancer.

CONCLUSIONS

Diagnosis of early cervical cancer is always a microscopic technic. Such evidence argues for a total hysterectomy if hysterectomy is being considered. It indicates more extensive treatment of cervicitis and erosion by electrocervical methods. Electroconization is recommended as a good method for diagnosis as well as treatment. Widespread use of cytology should increase the percentage of surgical cures.

The evidence argues for the advantage of an annual cytologic test by a selective method to detect early carcinoma. If, as the evidence indicates, early cancer is a microscopic disease, single biopsies, or even multiple biopsies which depend on visual demonstration for localization of site, may fail to detect the focus of growth.

Dr. Pund's series bear this out in a large group of cases. To date, we have picked out a large series of women (about 115) who show cells suggestive of carcinomatous tendencies using the spatula; yet in a surprising large number of these, single biopsies failed to detect any carcinoma. Those cases, however, which did have a complete conization and serial sections of the entire squamocolumnar junction of the cervix, yielded 36 preinvasive carcinomas and a still larger number of studies showing cells exhibiting the structure of cancer without a lesion large enough or definite enough to be labeled by the pathologist as a preinvasive carcinoma. Therefore, there was a rather large group of cases detected which were diagnosed as showing malignant tendencies or as showing a picture which has been regarded as precancerous. This group of precancers and cases showing cancerous tendencies without definite biopsies of malignant growth present a controversial group. We prefer, therefore, not to make too many claims of a specific nature regarding their malignant potentialities. In the meantime further evidence and knowledge of these cases is growing. While the end result of such cases would be interesting to know, they do warrant some treatment today, and in this type of case we have usually recommended either thorough electrocautery or removal of the diseased cervical tissue by conization. Such cases may then be followed by frequent cytologic studies, every two or three months, to detect possible tendencies toward recurrent growth.

It is our conclusion, however, that the described selective cytologic method gives a sensitive indication of growth changes in the squamous tissues in the region of the junctional area, and it may be possible simply to scrape off a beginning area of growth in tissues, leaving no further evidence to be found in the tissue biopsy. Many of us have seen cases in which the curet removed entirely small adenocarcinomas of the endometrium, leaving no further evidence of growth in the tissue sections following hysterectomy. One similar case has recently been encountered by Dr. Edwin R. Robertson of Kingston, Ontario. A small cervical carcinoma detected by cytologic scraping and confirmed by biopsy revealed no further evidence of cancer when multiple sections were studied from the surgically removed uterus.

Many of these cases showing only fragmentary cellular evidence of growth have been cases in which there was chronic cervicitis, and study of the nuclear changes in the cases of chronic cervicitis does give the impression that inflammation bears some relation to malignant growths in this organ. It is our belief, however,

that other factors¹⁴ are necessary to produce morphologic changes of a malignant character in the cells.

Until a real cure for cancer is found, a yearly cytologic test offers the next best thing in diagnosis and control of uterine cancer.

ABSTRACT OF DISCUSSION

DR. CHARLES E. GALLOWAY, Evanston, Ill.: The vaginal smear technic constitutes the greatest advancement in diagnosis and cure of cancer of the uterus in the last fifty years. Dr. Ayre's technic of gently removing the surface cells of the cervix is a reasonable procedure, but it requires the introduction of a vaginal speculum, and it furnishes one with many more cell types than are found when the secretions are obtained by a pipet from the vagina. It also is somewhat questionable as to whether more carcinomas may be diagnosed in this manner than can be diagnosed by the usual vaginal technic. The diagnosis of preinvasive carcinoma is controversial to some extent, and it is hoped that there will be some deaths from epidermoid carcinoma in order to back up some of these diagnoses. As in every other new procedure in medicine, we find that the lag between discovery and application is greater than it should be. This seems to be especially true whenever some effort is needed on the part of the practitioner in order to give his patient the benefit of the present day knowledge. Papanicolaou first applied the vaginal smear technic in the diagnosis of cancer of the uterus in 1923. But after all these years only an infinitesimal number of women are receiving the benefit of this simple, inexpensive test. At present, over 17,000 women die of cancer of the uterus every year in these United States. May we not consider most of these deaths as preventable? Our chief hope for reducing this terrible mortality lies in early diagnosis, because during the past fifty years nothing has been added to our armamentarium other than radium, roentgen rays and surgery. The smear technic may enable one to detect malignant growths before they can be seen or felt, and even before they have produced clinical symptoms. But adequately trained cytologists are lacking at the present time. At present, the world over, too many false positive vaginal smears are being reported due to inadequately trained cytologists. We must therefore train men and women to become expert and reliable in their ability to recognize malignant cells, not only in vaginal smears but also in urine sediment, sputum, gastric secretions and stools.

DR. WILSON FOOTER, Oakland, Calif.: Cervical cytology is one of several aids that can be used to facilitate early diagnosis of cancer of the cervix. None of them can help if it is not used, and it will not be used until the examiner has become aware that even the normal-appearing cervix in the patient without symptoms may harbor cancer. Although cancer is present in the cervix it must at least involve the surface in order that cells be shed and a diagnosis of cancer be possible by the smear method. In one illustrative case the cervix was hard and nodular and clinically was diagnosed as cancer. The cervical smear did not contain any malignant cells. On sectioning the surface epithelium was entirely normal. Deep in the stroma the lymphatics were involved with mucin-forming adenocarcinoma, extension from a Krukenberg tumor. Cancer can be present in the cervix and not be diagnosable by this method. Studies of the second case illustrate an early cancer resembling a laceration with eversion. The smear contains malignant cells and the biopsy shows deep invasion of the stroma. The cervix in the third case resembles an eversion. Suction curettage and biopsies of both cervical lips showed no evidence of malignant growth. Malignant cells were found on aspiration, and in the removed cervix there was extensive surface carcinoma and invasion in one small area. Case 4 presents a carcinoma of the cervical canal with a lobulated sharply demarcated leukoplakia surrounding the external os. Original biopsies from the leukoplakia did not reveal the cancer, smears contained cancer cells, and subsequent biopsy of the cervical canal showed invasive carcinoma. In diagnosing early cancer of the cervix

cytologic examinations do not replace the biopsy. On the other hand, the biopsy may fail to reveal cancer, when the smear contains exfoliated cancer cells. As in 2 of the cases presented, the diagnosis of cancer was made by smears after negative biopsies. The early diagnosis of cancer of the cervix depends on complete examination even in the absence of any symptoms and the intelligent use of all of the diagnostic aids at our disposal.

DR. KARL MARTZLOFF, Portland, Ore.: It is important to stress that early cancer of the cervix has nothing about it that distinguishes it grossly from some of the other benign lesions of the cervix. The use of the curet is a modification of the selective curettage technic that has long been used. It will probably prove to be more satisfactory than the vaginal smear technic, particularly when Papanicolaou staining methods are utilized. It is regrettable that the vaginal smear is being propagandized in the lay press by members of the American Cancer Society as a diagnostic procedure. Obviously such statements are untrue and harmful. As a consequence, the time is coming when a physician will probably be subjected to the hazard of unwarranted suits for malpractice if he does not employ the vaginal smear technic. Dr. Ayre has used the term "preinvasive cancer" to describe a noninvasive carcinomatoid change. It is a dangerous term, because probably there is no one who can positively say that this lesion is destined to become an established cancer. Still the term "preinvasive cancer" presupposes just such diagnostic acumen. If such difficulties can occur with well prepared tissue carefully obtained for biopsy, it becomes evident that the vaginal smear with its scattered and unrelated elements presents even greater problems. When desquamated cells possessing the appearance of neoplasia are observed in a vaginal smear preparation, one is confronted by three questions: Are these cells truly neoplastic? If they are, do they come from a bona fide cancer or from an area of noninvasive carcinomatoid change? The first question can generally, but by no means always, be answered correctly. The last two cannot. Therefore, the "positive" vaginal smear is not diagnostic of cancer. A "negative" smear also does not exclude cancer. Most reports concerning the reliability of the vaginal smear method do not specify whether their preparations come from patients with well developed cancer where a brief history and careful speculum examination by the family physician would permit an instant and generally correct clinical appraisal, or whether their material comes from patients in whom no suspicion of cancer exists. It is a fair assumption that the former group provide the bulk of the clinical material and that the family physician and informed patient are still the answer to early diagnosis.

DR. J. HEYMAN, Stockholm, Sweden: At the gynecology clinic of Radiumhemmet in Stockholm, we see a great number of patients with cancer of the uterus. We also see a great number of patients with irregular bleeding, and a number of patients are annually referred to us suspected of having a uterine carcinoma. Sweden is a sparsely populated country, and it is easy for us to follow all the patients referred to us. And we do follow them. Since 1914, any patient of the type mentioned who was referred to us has been followed. Our follow-up is 100 per cent. It is a fact—and I think a rather surprising fact—that a carcinoma has never developed in a patient in whom we failed to diagnose the cancerous lesion on clinical examination or on biopsy. There seems to me thus to be some slight discrepancy between the experience of the cytologist and the clinician.

DR. A. E. RAKOFF, Philadelphia: The value and limitation of a cytologic method have been well enumerated. I should like to cite what our results have been in the routine application of these methods in Philadelphia, where during the past several years we have been using the vaginal smear method also as part of the routine examination given to women coming into the Health Maintenance and Cancer Prevention Detection Clinics. Prior to using this method, we undertook to study routinely 500 women as they appeared for admission to the wards of the Jefferson Hospital, taking a single set of smears (consisting

14. Ayre, J. E.; Chevalier, P. M., and Ayre, W. B.: A Comparative Study of Vaginal and Cervical Cornification in Human Subjects, *J. Clin. Endocrinol.* 7: 749-752, 1947.

of two smears) from the vagina by the method of Papanicolaou. These smears were read by several investigators who had had considerable experience with this method, who did not see the patients, who did not know the histories and who did not know the results until after the patients were operated on. Our final results gave a correlation of 94.8 per cent correct, positive and negative. However—and this I believe to be the important point—in 63 cases, positive for cancer of the uterus (57 cervical, 6 fundal), we missed 19, or 30 per cent. In the negative cases we missed only 7, or 1.6 per cent. This indicates that the percentage of missed positive cases by a single set of smears when they are taken in a routine fashion may be rather high. This we feel to be the chief limitation of this method for routine purposes. On the other hand, in going back to these cases later, or in studying similar cases in which there is suspicion of cancer, by taking repeated smears we have almost invariably been able to make a positive diagnosis. When there is no suspicion of cancer, and when therefore only one set of smears would be furnished for routine examination, we feel that the vaginal smear method has distinct limitation. More recently, since the publication of Dr. Ayre's work, we have also been taking, in selected cases, cervical and vaginal smears. In some instances we were able to find positive cervical smears, but not vaginal smears. We have also had in several instances the reverse happen; that is, a positive vaginal smear, with a negative cervical smear. For that reason we are now making it routine to take both cervical and vaginal smears to eliminate this inherent defect in the method.

DR. J. ERNEST AYRE, Montreal, Canada: The comparison of the various methods of obtaining smears is important. Since we are dealing with minute elements as small as cells, we are working in a field where precision is extremely important, and I think that for successful and accurate cytologic diagnostic results, it is essential that precision be exercised in three different departments: (1) in the method of taking the smear; (2) in the staining with Papanicolaou's stains, and (3) in the interpretation by one who is familiar with cancer cytology and normal cytology. So far as the method of taking the smear is concerned, the vaginal smear, of course, has the great advantage of being easily taken. At the same time, its very ease perhaps renders it susceptible to error in that a nurse unfamiliar with the method, or even the patient, may take the test and may aspirate secretion from the roof of the vagina. Often we found that the smear was taken from just inside the introitus, missing the vaginal pool. I think that such errors perhaps account for some of the limitations of the method that Dr. Rakoff spoke of finding. In our own experience we have had a number of cases in which we failed to find the cells in the vaginal aspiration, whereas we did find them in high concentration in the selective cervical scraping. Vaginal smears will show cancer cells in clinical cancer but it takes longer to find them than in the more concentrated cervical smear. The selective scraping is, in our experience, the method of choice for detection of preclinical cancer. In order to increase the efficiency of the cytologic method, it is worth the extra trouble of inserting a speculum and going directly to the point of origin of the squamous cells which we want to examine. In this way we obtain a selective cell test for the common type of cervical cancer which will tend to increase the accuracy of the method and save more lives through earlier diagnosis.

Rupture of Interventricular Septum.—The clinical diagnosis of rupture of the interventricular septum is based on the sudden appearance of a loud systolic murmur, best heard over the fourth and fifth intercostal spaces to the left of the sternum following myocardial infarction. On occasion, a thrill can be palpated over the same areas. Furthermore, this systolic murmur becomes harsher with time. Auriculoventricular conduction defects are rarely present in this condition, and the electrocardiographic tracings show changes consistent with myocardial infarction, and right ventricular strain. The period of survival after the accident may vary from a few hours to eight months.—Rivera-Diaz, R. S., and Miller, A. J.: Rupture of the Heart Following Acute Myocardial Infarction. *American Heart Journal*, page 126, January 1948.

CEREBRAL ARTERIOGRAPHY IN SUBARACHNOID HEMORRHAGE

I. S. WECHSLER, M.D.

and

S. W. GROSS, M.D.
New York

Despite the fact that the clinical diagnosis of spontaneous subarachnoid hemorrhage is comparatively easy to make and the pathology of the syndrome is fairly well understood, there still are enough gaps in our knowledge to justify further investigation of the subject. There are, indeed, a number of excellent reviews of both the clinical and pathologic aspects of the syndrome, but the statistics on the former are sometimes misleading and the studies of the latter are not always conclusive. Often one can make clinically the diagnosis of ruptured cerebral aneurysm, and not infrequently one may venture a correct opinion as to localization based on clinical signs and symptoms. But aneurysm is not the only cause of spontaneous subarachnoid hemorrhage, and necropsy does not always reveal it even when it is. Martland,¹ basing his views entirely on postmortem studies, stated:

We believe that most of those cases of spontaneous subarachnoid hemorrhage which recover (fifty per cent, according to some clinicians) are probably not due to "leaking" or ruptured intracranial aneurysms, but rather to some unexplained infection or some as yet unknown cause. There is little anatomic proof that intracranial aneurysms leak, rupture and heal, or bleed at various intervals, and less proof that intracranial aneurysms may become thrombosed and disappear.

Whether or not necropsy always reveals the cause of the hemorrhage, a diagnosis after death is admittedly of little help to a patient and not much of a guide to his treatment. The diagnostic reasoning in most cases of spontaneous subarachnoid hemorrhage has always been, and largely still is, circular in type and repetitious in effect. Some neurologists continue to rely on repeated lumbar puncture; most, including ourselves, do not; but nearly all have hitherto pursued what is known as conservative treatment. Obviously conservative treatment is no treatment at all and merely is a euphonious justification for doing nothing, while expectant treatment means waiting for the patient to die or to get well without even the benefit of effort at treatment. We believe that much of the uncertainty as to diagnosis and prognosis can be dispelled by cerebral arteriography. In a number of cases it provides definite indications for successful treatment and in some may lead to the prevention of recurrent bleeding. The method, then, can be not only of diagnostic but also of therapeutic importance.

After the introduction of arteriography by Moniz,² both practical and theoretical objections were raised by many. The theoretical ones refer to the danger of the method itself. On the basis of our own experience we can say with assurance, after employing the diagnostic method both in the acute and subacute stages of subarachnoid hemorrhage, that the injection itself for the visualization of the arteries is a safe procedure. We have observed no untoward complications in any of our cases. The practical objection to "thorotrast"

(colloidal thorium dioxide) is valid. "Thorotrast" is a radioactive substance, and its deleterious effects persist because it is not excreted. With the introduction by Gross³ of "diodrast" (iodopyracet), which is non-radioactive and is rapidly excreted, arteriography can now be carried out with safety, and even multiple or

Fig. 1 (case 1).—Vascular malformation in left frontoparietal area.

repeated injections may be made with impunity. Since we began to use "diodrast" for arteriography in 1939, for the study of subarachnoid hemorrhage and the investigation of cerebral vascular lesions without hemorrhage, we, as well as others,⁴ have extended the use of cerebral arteriography as a diagnostic method. Recent studies of brain tumors have demonstrated the value of the method in conditions other than vascular anomalies. The cases about to be described illustrate, we believe, the diagnostic value of visualizing by means

Fig. 2 (case 2).—Diffuse vascular malformation in right parieto-occipital region.

of arteriography the nature of some of the vascular anomalies or aneurysms causing subarachnoid bleeding and the indications for arterial ligation, brain exploration or roentgen treatment.

REPORTS OF CASES

This paper deals with 10 cases of subarachnoid hemorrhage in which arteriography was performed during the acute or subacute phase.

CASE 1.—*Vascular malformation of the left frontoparietal area with repeated attacks of subarachnoid bleeding.*

S. C., a white woman aged 30, was hospitalized eight years before in another institution, where the diagnosis of subarachnoid hemorrhage was made. She was unconscious for seventy-two hours at that time and had right hemiplegia. She was admitted to the Mount Sinai Hospital for the first time on Aug. 26, 1939. Four days previously, while in apparent good health, she suddenly became comatose, and right hemiplegia and rigidity of the neck developed. The cerebrospinal fluid was frankly bloody. She gradually improved on bed rest and was discharged on Oct. 26, 1939. At home she complained of headache and right-sided seizures. On Oct. 1, 1941 she began to vomit and became drowsy, and her neck became stiff. She was readmitted four days later with a right hemiplegia and aphasia. The spinal fluid contained 40,000 red blood cells per cubic millimeter. On Nov. 21, 1941 left cerebral arteriography demonstrated a vascular malformation in the left frontoparietal area (fig. 1). The left common carotid artery was ligated

Fig. 3 (case 3).—Vascular malformation in right posterior parietal area.

and she improved. She was seen in the follow-up clinic up to Dec. 14, 1944, and she had no further attacks of subarachnoid hemorrhage.

Comment.—This patient had several attacks of subarachnoid bleeding, each with right hemiplegia and aphasia. Arteriography demonstrated a vascular malformation in the left frontoparietal area. She was observed for three years after ligation of the common carotid artery. During this period no attacks of subarachnoid bleeding occurred.

CASE 2.—*Vascular malformation in the right parieto-occipital area.*

L. K., a white woman aged 43, was admitted to the hospital in 1946 with the history of repeated episodes of subarachnoid hemorrhage since the age of 8. She had five previous admissions to Mount Sinai Hospital, each time because of sudden onset of headache, stiff neck, photophobia and vomiting. On this, her sixth admission for the same complaints, she had, in addition, left central facial weakness and a Babinski sign on the left. Lumbar puncture showed xanthochromic fluid under a pressure of 195 mm. Right cerebral arteriography done on Jan. 11, 1946 disclosed a vascular malformation in the right parieto-occipital area (fig. 2). Radiotherapy was given. The patient remained fairly well up to June 2, 1946, when she had another typical attack of subarachnoid bleeding, from which she slowly recovered.

3. Gross, S. W.: Cerebral Arteriography in the Dog and in Man with a Rapidly Excreted Organic Iodide, *Proc. Soc. Exper. Biol. & Med.* 42: 258, 1939.

4. List, C. F., and Hodges, F. J.: Intracranial Angiography, *J. Neurosurg.* 3: 25, 1946.

Comment.—The carotid artery was not ligated in this case since the lesion was not noted in the wet roentgen film. A course of radiotherapy did not prevent subsequent subarachnoid bleeding.

CASE 3.—*Vascular malformation with sudden onset of subarachnoid bleeding.*

B. S., a white woman aged 40, had been in good health except for migraine of many years' duration. She had had mild hypertension since the age of 37. In September 1946, she was suddenly seized with severe pain above the right eye, followed by vomiting. Two days later left hemiplegia developed. Within a few days she became confused, restless and incontinent of urine and feces. On admission to the Mount Sinai Hospital she was apathetic but facetious. She had left hemiparesis, left homonymous hemianopsia and bilateral choked disks. The spinal fluid showed xanthochromic fluid. Roentgen examination of the skull showed displacement of the pineal gland to the left, and the electroencephalogram indicated a neoplasm in the right posterior temporal region. The patient slowly improved during the next three weeks. On Dec. 10, 1946 a right cerebral arteriogram disclosed an extensive vascular malformation in the right

Fig. 4 (case 4).—Vascular malformation in left parieto-occipital area.

posterior parietal area (fig. 3). The right common carotid artery was ligated. At the time of discharge, Dec. 22, 1946, she was greatly improved. The fundi were normal. When seen in March 1947, she was well.

Comment.—In this case the history suggested a ruptured aneurysm of the circle of Willis while the roentgenograms and electroencephalogram favored a tumor. Arteriography demonstrated a large vascular malformation.

CASE 4.—*Malformation in right parieto-occipital area with acute subarachnoid hemorrhage.*

S. C., a white woman aged 30, had one previous attack of subarachnoid hemorrhage; she was comatose for several days but eventually made a good recovery. In September 1946 she had one generalized convulsion, followed by right-sided headache, and on Jan. 14, 1947 a second one. She was readmitted to the Mount Sinai Hospital the following day. At this time there were no neurologic abnormalities. The spinal fluid was clear and colorless. An electroencephalogram showed diffuse 6 per second activity. A right cerebral arteriogram (fig. 4) revealed a vascular malformation in the right parieto-occipital area. The right common carotid artery was ligated. The patient was discharged on Jan. 31, 1947. She has remained well except for two generalized seizures which occurred when she failed to take diphenylhydantoin sodium.

Comment.—The original clinical diagnosis was ruptured cerebral aneurysm, but the arteriogram showed a vascular anomaly.

CASE 5.—*Capillary hemangioma of the left occipital area.*

M. R., a white man aged 37, was in good health until seven weeks before admission, when he had a sudden attack of vomit-

Fig. 5 (case 5).—Capillary hemangioma in left occipital area

ing and loss of consciousness for a few hours, followed by further vomiting, violent headache, rigidity of the neck, dizziness and drowsiness. A lumbar puncture done at another hospital yielded a grossly bloody fluid under increased pressure. He was admitted to the Mount Sinai Hospital on Jan. 29, 1947, seven weeks after the initial attack. The neurologic examination at this time showed no abnormalities. The spinal fluid was colorless; there were no cells, and the total protein was 86.5 mg. per hundred cubic centimeters. The electroencephalogram showed a large amount of diffuse symmetric activity, 4 to 6 per second without focal accentuation. Right cerebral arteriography showed no abnormalities. Left arteriography, done a few days later,

Fig. 6 (case 6).—Aneurysm of left internal carotid artery at junction of posterior communicating artery.

showed a telangiectatic malformation in the left occipital area (fig. 5). High voltage roentgen therapy was given, and two months later the patient was free of headache and dizziness.

Comment.—As the vascular abnormality was not recognized in the wet roentgen film, the common carotid artery was not ligated, but when the lesion was seen to consist of small vessels, which appeared to be radiosensitive, roentgen therapy was instituted.

CASE 6.—Supraclinoid aneurysm with subarachnoid hemorrhage.

R. G., a white woman aged 33, had a sudden attack of pain in the back of the head; two days later a complete left third nerve paralysis developed. Four weeks afterward she suddenly became unconscious and had bloody spinal fluid. After three weeks' hospitalization she improved generally, but the left third nerve paralysis persisted. In addition to diplopia she complained of pain around the left eye. An arteriogram done Aug. 14, 1946 showed a supraclinoid aneurysm probably arising at the junction of the internal carotid and posterior communicating artery (fig. 6). The left common carotid artery was ligated. The third nerve paralysis slowly improved, and the pain around the eye disappeared. She has remained in good health up to the present time.

Comment.—The pain in the eye, which pointed to involvement of the ophthalmic branch of the trigeminal nerve, and the oculomotor paralysis left no doubt that the bleeding was due to rupture of an aneurysm of the anterior portion of the circle of Willis.

CASE 7.—Supraclinoid aneurysm with severe subarachnoid bleeding.⁵

M. W., a Negro woman aged 23, began to have severe occipital headache on Jan. 25, 1947. The next day she became drowsy, vomited several times and was admitted to the hospital.

Fig. 7 (case 10).—Vascular malformation in left parietal area.

Examination showed rigidity of the neck and a bilateral Babinski sign. The spinal fluid was grossly bloody. On Feb. 3, 1947, she had a generalized convulsion. She seemed to improve slowly up to Feb. 13, 1947, when she had another convulsion followed by a left hemiplegia with forced deviation of the eyes to the right, and stupor. Arteriography done on February 22 showed a berry aneurysm near the bifurcation of the right internal carotid artery. The right common carotid artery was ligated. She continued in stupor, but spinal puncture showed no evidence of new bleeding. On February 26 a craniotomy was done. The aneurysm was found springing from the middle cerebral artery near its junction with the internal carotid artery. A silver clip was placed around the base of the aneurysm. The patient improved temporarily. She became less stuporous and began to take food by mouth. While apparently doing well she took a sudden turn for the worse; she died March 23, almost one month after intracranial ligation of the aneurysm. Autopsy was not permitted.

Comment.—This patient was in poor condition from the onset of her illness. After ligation of the common carotid artery in the neck there was no further evidence of fresh bleeding.

5. This case and the next one are from the service of Drs. Savitsky and Gross at the Lebanon and Morrisania hospitals.

CASE 8.—Subarachnoid bleeding with large intracerebral clot.

W. T., a white man aged 39, had had a head injury without loss of consciousness nine months previous to his hospital admission on March 26, 1947. After the head injury he became forgetful and irritable but otherwise seemed well. On the day of admission a left hemiplegia suddenly developed with twitching of the left side of the face. He complained of severe right-sided headache, became drowsy and finally unconscious. Just before admission he had a severe generalized convulsion. The spinal fluid was grossly bloody under a pressure of 360 mm. He had a stiff neck, conjugate deviation of the eyes to the right, left homonymous hemianopsia and a left hemisensory syndrome. The fundi showed early choked disks. On April 12, a right cerebral arteriogram was done, followed by a right subtemporal decompression and evacuation of a large intracerebral hematoma from the right temporal lobe. After this the patient's mental condition and eye signs improved rapidly. Spastic paralysis of the left upper extremity persisted (as of May 20, 1947).

Comment.—Although the aneurysm was not demonstrated in the arteriogram we believe that the patient had an aneurysm of the right middle cerebral artery which burrowed in the temporal lobe and finally ruptured.

CASE 9.—Aneurysm of right internal carotid artery near its bifurcation, with severe subarachnoid bleeding.

S. R., a white woman aged 28, had been in good health except for periodic migraine. On March 24, 1947, she suddenly became dizzy and rapidly lost consciousness. For a few days prior to this episode she had pain above the right eye and drooping of the right eyelid. She was admitted to the hospital, almost in a moribund state. Her pupils were widely dilated, all four extremities were weak, and the blood-pressure was 80 systolic and 50 diastolic. The spinal fluid was grossly bloody under a pressure of over 600 mm. Within twelve hours she improved slightly, but the temperature was 103 F. and her neck was rigid. On March 27 a left hemiplegia was noted. On March 30 she sank into deep coma. The spinal fluid was still grossly bloody. Arteriography disclosed an aneurysm of the right internal carotid artery near its bifurcation. The right common carotid artery was ligated. The patient remained comatose and died ten hours later.

Comment.—This patient was almost moribund from the onset of her first attack of subarachnoid bleeding. She would have died even if arteriography and carotid ligation had not been done.

CASE 10.—Multiple vascular malformations of the brain.

S. G., a white youth aged 17, was admitted to the hospital on Oct. 5, 1939.

Past History: The patient's birth was normal; he did not talk until the age of 5, and is said to have had "poliomyelitis" at the age of 5½, followed by weakness of the left upper extremity. In 1938 he had a generalized convulsion. In September 1939 sudden weakness of the right upper extremity developed and he became stuporous. On admission he showed a right hemiplegia, right hemihypesthesia, right astereognosis, bilateral choked disks, rigidity of the neck and a pulse of 54. Lumbar puncture showed xanthochromic fluid with crenated red blood cells under a pressure of 480 mm. Left cerebral arteriography on Oct. 9, 1939, showed a vascular malformation in the left parieto-occipital region. A left subtemporal decompression was done and the cerebral veins in the exposed area appeared greatly enlarged. The patient's condition began to improve rapidly. Radiotherapy was started on Oct. 19, 1939. The patient continued to improve. On Nov. 28, 1939 the fundi were normal. He remained well until March of 1943, when he began to have jacksonian seizures involving the left hand, but he continued to work up to May 15, 1946, when he was readmitted to the Mount Sinai Hospital. On examination a bruit was heard over the left temporal region. A left arteriogram showed a vascular malformation in the parietal area (fig. 7). The common carotid artery was ligated, and though

the bruit persisted it was less intense. Because of a sudden episode of loss of speech in October 1946, he was given radiotherapy, and he improved once more.

Comment.—The patient evidently had bilateral vascular malformations of the brain. What was diagnosed at the age of 5½ as poliomyelitis probably was a subarachnoid hemorrhage. Twelve years later he had another subarachnoid hemorrhage, this time with right hemiplegia. Arteriography, subtemporal decompression and radiotherapy were followed by recovery. When jacksonian seizures set in and a bruit was detected arteriography was done again. In retrospect, a right arteriogram should have been made, since a previous left arteriogram already had demonstrated the vascular anomaly on the left side.

COMMENT

The statement frequently made that spontaneous subarachnoid hemorrhage generally is the result of rupture of a cerebral aneurysm,⁶ especially of the circle of Willis, is not borne out by our observations. These cover a larger number of cases than are recorded in this paper. Of the rather small series of 10, 6 were the result of vascular malformations demonstrated by arteriography, and only 4 of aneurysms. In 3 of the latter the aneurysms were near the bifurcations of the carotid, and in the fourth the aneurysm was presumed to have burrowed into the temporal lobe, where it ruptured and caused a large intracerebral hemorrhage.

Three of the patients in our series of cases who had several recurrent episodes of subarachnoid bleeding were found to have vascular malformations. The 3 others with vascular malformations were observed during their initial attack or shortly thereafter. It seems to us that recurrent subarachnoid hemorrhages with recovery, with or without sequela, are more likely to be the result of vascular malformations than of aneurysms. Aneurysms are more likely to be fatal during the first attack or the second, unless successful ligation can be carried out after demonstration by arteriography. Since the symptoms of subarachnoid hemorrhage are mainly general and the clinical signs essentially meningeal, it is usually difficult to state with assurance either the nature or the location of the lesion. Visualization of the arteries is the only method of making the diagnosis certain. For the first time a method is available which provides definite therapeutic indications, be they arterial ligation, intracranial exploration or deep radiation.

Ligation of the common carotid artery on the side of the lesion was done in 4 patients with vascular anomalies; 2 others were treated by radiation. In 3 patients with aneurysms the common carotid alone was ligated; in the fourth intracranial ligation was done in addition. The reason for ligating the common carotid and not the internal carotid is that it is safer. The circulation is reduced only about 50 per cent and no preparation, such as gradual compression of the artery, is necessary. Also, there is little danger of convulsions or hemiplegias. The 2 patients who died after ligation were practically moribund, and it was felt that they would not have survived anyway. The arteriography and the ligation were measures of last resort in both of them. Exploration was done only once in a patient with a vascular anomaly,

because we were of the opinion that intracranial exploration did not offer much, whereas arterial ligation or high voltage radiation promised considerably more.

As to recurrences, all patients who had ligations for cerebral vascular malformations have so far had no subsequent attacks of bleeding. Two of the cases are rather recent, so that one cannot speak with absolute assurance as to recurrence in them. In 1 case of vascular malformation, in which treatment was by radiation but without ligation of the carotid, there were two recurrences. This was one of our early cases, when our experience was limited. The wet roentgen plate was not properly interpreted at the time. Afterward ligation was not done for other reasons, which we do not now regard as valid.

The question of when to do an arteriogram and when to ligate the artery perplexed us a great deal at first. In our inexperience we were afraid to do an arteriogram immediately after the hemorrhage occurred or in the acute stage, and the procedure was deferred for weeks and weeks. Then when the patient recovered it was not done either because the patient refused to have it done or we hesitated too long. As the technic was perfected and skill in reading films increased, and as we learned that arteriography was both simple and safe, we ventured to do it earlier and earlier until now we no longer hesitate to do it in the very acute phases of the hemorrhage.

SUMMARY

Many cases of spontaneous subarachnoid hemorrhage, especially with focal lesions, are the result of vascular malformations rather than aneurysms. Recurrences are more likely to occur in vascular malformations. Ruptured cerebral aneurysms are more apt to cause death in the first or second attack.

Only visualization by arteriography can make certain either the location or the nature of the lesion in most of the cases. Arteriography is not only a diagnostic method but a reliable guide to treatment. It is a simple and safe procedure.

Ligation of the common carotid carries practically no risk with it. Surgical treatment, whether ligation alone or in combination with deep radiation, will prevent recurrence in many cases.

His Father Was a Physician.—Adolph Kussmaul was born in 1822 at Graben, near Karlsruhe, Germany. His grandfather had been a military barber-surgeon and his father was a physician. Kussmaul received his medical education at Heidelberg and then settled down as a country practitioner. Serious illness, however, compelled him to abandon medical practice. He taught at Heidelberg from 1855 to 1859, when he accepted the chair of internal medicine at Erlangen. In 1863 he accepted a similar position at Freiburg. Kussmaul was instrumental in initiating a new scientific movement that was to become of great importance in the development of clinical medicine. This was the idea of functional diagnosis, according to which information regarding the early stage of an affection of an organ could be obtained by testing its functions. In 1876 Kussmaul became professor at Strassburg, where he remained until his retirement in 1888. Such time as he could spare he devoted to his autobiography, "Reminiscences of the Youth of an Old Doctor," and the unfinished sequel "A Teacher in Heidelberg."—Rosen, George, and Caspari-Rosen, Beate: 400 Years of a Doctor's Life, New York, Schuman's, 1947.

SPONTANEOUS SUBARACHNOID HEMORRHAGE OF ANEURYSMAL ORIGIN

Factors Influencing Prognosis

WALLACE B. HAMBY, M.D.
Buffalo

Morgagni¹ of Padua in 1761 first described an intracranial aneurysm, and seventeen years later Biunni² of Milan described a case of subarachnoid hemorrhage, the cause of which was found at autopsy to be a ruptured aneurysm of the circle of Willis. For the next seventy-five years the continental medical literature carried reports of hemorrhages and of aneurysms with little evidence of correlation between the two subjects. In 1859 Gull³ of Guy's Hospital correlated these reports and emphasized that "spontaneous subarachnoid hemorrhage" usually was due to rupture of an aneurysm of one of the arteries on the base of the brain. In 1924 Symonds,⁴ also of Guy's Hospital, and in 1941 Richardson and Hyland⁵ of Toronto brought the subject up to date in complete monographs. Recent reports by Magee⁶ and by Wolf, Goodell and Wolff⁷ have contributed data especially concerning prognosis.

This report is based on a study of the records of 130 patients suffering from subarachnoid hemorrhage at the Buffalo General Hospital in the years 1922 to 1935, inclusive. Seventy-five of the patients were women and 55 were men. They varied in age (fig. 1) from 7 months to 80 years. The age distribution was: 1 in the first decade of life, 1 in the second, 10 in the third, 24 in the fourth, 43 in the fifth, 30 in the sixth, 15 in the seventh and 6 in the eighth.

ETIOLOGY OF SPONTANEOUS SUBARACHNOID HEMORRHAGE

For the purpose of this review, the term spontaneous subarachnoid hemorrhage was restricted to include those cases of subarachnoid hemorrhage occurring without external trauma and without obvious cause for hemorrhage or preexisting disease. Cases of primary cerebral hemorrhage with secondary leakage into the subarachnoid space, bleeding brain tumors, blood dyscrasias, etc., were not included.

In 130 cases of subarachnoid hemorrhage, the cause of the hemorrhage was determined in 47 patients, 41 at necropsy and 6 at operation. Ruptured aneurysms were found in 44 of the 47 patients (93.6 per cent). Two aneurysms were found in each of 2 patients, making a total of 46 aneurysms. The origin of the hemorrhage was from a ruptured spinal artery in 1 case, from a ruptured arteriosclerotic vessel in 1, and in 1 case of bilateral occipital hemorrhages with subdural hematoma and subarachnoid hemorrhage the

origin of the bleeding was not found at necropsy. Of the 46 aneurysms, 44 were classified as being of "berry" type, one mycotic and one leaking arteriovenous (carotid-cavernous) aneurysm. It seems reasonable to assume that in the unproved cases the percentage due to aneurysm would parallel that of the proved cases.

A much more diverse etiology is obtained if all cases of subarachnoid bleeding are included. In discussing the etiology of subarachnoid hemorrhage Courville⁸ listed the cause of 149 cases found in the study of 1,500 autopsies. He concluded that external trauma probably causes more than half of all instances of subarachnoid hemorrhage. In this group were listed 35 cases of injuries and hemorrhagic diseases of the newborn, 32 due to arteriosclerosis and hypertension, 16 to ruptured aneurysms, 11 to embolism, etc.

Sands⁹ analyzed the observations on 120 cases of subarachnoid hemorrhage: Twenty-two per cent could not be classified as to cause; 7.5 per cent were attributed to trauma; 25 per cent to arteriosclerosis; 13.6 per cent to infectious diseases; 20.4 per cent to intracranial aneurysms, and a smaller number to cerebral neoplasms, blood dyscrasias and cerebral hemorrhages. Kernohan

Total.....	20	15	11	46	

* In this table the main stem vessel is named. If the aneurysm occurred at the junction of the internal carotid and the posterior communicating, it is designated an aneurysm of the internal carotid. The carotid extends to the origin of the anterior cerebral artery.

and Woltman¹⁰ reported 4 cases of patients dying after operation for other cause, of subarachnoid hemorrhage due to primary necrosis of vessels, which they suspected was due to focal infarcts in the vessel walls. Bagley¹¹ reported 1 case of a man who suffered an attack of massive subarachnoid hemorrhage due to rupture of an internal carotid artery which eventually healed. Symonds⁴ in 124 cases found the cause of hemorrhage in 71. It was due to arteriosclerosis in 24, to syphilis in 10 and to aneurysms in 11. In 41 of the 124 cases the cause of hemorrhage was obscure. He asserted that hemorrhages of unexplained origin are often caused by aneurysms that are not found, since they frequently are minute and always are deeply imbedded in the clot and thus easily escape notice at autopsy.

Gull³ observed that the apparent rarity of aneurysms as the cause of hemorrhage probably was related to the fact that they were not looked for. He noted that they are difficult to find unless they are specifically

sought out. "Whenever young persons die of symptoms of invanescent apoplexy and after death large effusion of blood is found, especially if the effusion be over the surface of the brain in the meshes of the pia mater the presence of an aneurysm is probable." Schmidt¹² emphasized that failure to find an aneurysm

Fig. 1.—Graphic distribution of patients according to age.

during a routine postmortem examination does not exclude that probability. He believed that the great majority of, and perhaps all, spontaneous subarachnoid hemorrhages resulting in death were due to aneurysms.

It is evident that subarachnoid bleeding can occur in a variety of diseases. Usually the underlying disease is evident, however, and the analysis of this series leads to the conclusion that even in the presence of arteriosclerosis the origin of spontaneous subarachnoid hemorrhage is usually from a ruptured aneurysm of one of the arteries in or near the circle of Willis.

Location of Aneurysms.—The location of the aneurysms in this series is shown in table 1 and diagram-

Fig. 2.—Diagrammatic presentation of location of aneurysms found at autopsy and at operation. Dotted lines indicate double aneurysms in 2 patients.

matically in figure 2. Twenty of the lesions were on the left side of the circle of Willis, eleven on the right and fifteen in the midline. In reported proved cases, the majority of aneurysms has been found on the anterior half of the circle of Willis. In this series this

observation was confirmed, forty examples being found on the carotid and six on the basilar segments of the circle.

INTRACEREBRAL HEMATOMAS

Of the 44 fatal cases of subarachnoid hemorrhage due to rupture of aneurysm, concomitant intracerebral hematomas were found in 23 (52 per cent) (fig. 3). The frontal lobe was involved in 17 cases. The hemorrhage originated from the anterior cerebral or communicating vessels in 12 of these, from the middle cerebral in 3 and from the internal carotid artery in 2. The temporal lobe was involved in 5 cases, by hemorrhage from the middle cerebral artery in 3 and from the posterior cerebral and posterior communicating in 1 case each. In one hematoma of the occipital lobe the vessel of origin of the hemorrhage was not found.

In 4 additional cases that were not examined at autopsy, intracerebral hematomas were found and evac-

Fig. 3.—Location of intracerebral hematomas and the vessels of origin of the hemorrhage.

uated surgically. One patient recovered and 3 died. In 2 of the fatal cases the origin of the hemorrhage was found in aneurysms of the anterior cerebral arteries, and in the other in a mycotic aneurysm.

Clinical evidence of major cerebral damage accompanying spontaneous subarachnoid hemorrhage, especially in the presence of increasing intracranial pressure, should lead the clinician to suspect the presence of an intracerebral hematoma, since this lesion is found at necropsy much more frequently than is occlusion of a major cerebral artery.

CLINICAL COURSE AND PROGNOSIS

Recovery from the initial attack has been reported in approximately 50 per cent of patients. In this series 48.5 per cent recovered. Analysis of the clinical history and physical findings in this series yielded little diagnostic information that has not been described earlier. Various data were compared in the clinical

12. Schmidt, M.: Intracranial Aneurysms, Brain 53: 489-540, 1931

courses of patients who survived and those who died in an attempt to discover a better basis for prognosis in the individual case.

Onset.—The onset of symptoms was sudden in 90 per cent of patients, 10 per cent having vague, non-specific prodromes.

Character of Onset.—1. Head pain was the initial symptom in 69 of the 130 patients. Since this symptom is practically universal within a short time after onset, the percentages are not considered significant. Sixty-five per cent of those who recovered and 42 per cent of those who died recorded this as their first symptom. 2. Unconsciousness was the first sign in 42 patients. Of these, 29 (69 per cent) died and 13 (31 per cent) recovered. This may be significant, since in this series the chances of survival of a patient with unconsciousness as the presenting sign were only 3 to 7. 3. Less common initial symptoms were: paralysis in 4 patients, of whom 3 died; convulsions in 2, both of whom died, and dizziness in 2, both of whom recovered.

Circumstances of Onset.—Richardson and Hyland⁵ found that the activity of the patient at the time of hemorrhage was of little importance in determining onset or severity. The patients were at rest in bed, standing or walking in 78 per cent of cases. Undue

increased and found in 52 cases that systolic pressure was lower than 150 mg. of mercury. He believed that whatever the cause of the leak, increased blood pressure should not be implicated. The level of blood pressure after the acute episode, however, is no criterion of what it might have been at the moment of rupture of the aneurysm. Wolf, Goodell and Wolff⁷ found that the majority of their patients were engaged in ordinary activity when the rupture took place. Excessive activity was noted rarely before the hemorrhage.

In our series, also, the majority of patients were engaged in ordinary activities at the time of onset of hemorrhage. A few were engaged in activities that might elevate their blood pressure, such as swinging a sledgehammer at work, playful wrestling, coitus, polishing or washing a floor, carrying an outboard motor and moving heavy furniture. More commonly the patient was at his usual work, driving a car, walking, sitting, standing and in several instances was asleep. The patient's activity at the time of the onset was not judged worthy of specific record in the majority of instances in this series.

AGE

Age was not a determining factor in this series (fig. 1). The ages of patients who recovered ranged from 7 months to 74 years, an average of 45 years. The ages of those who died ranged from 25 to 80 years, an average of 48.4 years. This is contrary to the experience of Richardson and Hyland,⁵ who found the average age of patients who died to be ten years higher than that of the survivors. Magee⁶ found that 6 per cent of his patients were under 20 years of age, 50 per cent were in the third decade, 37 per cent in the fourth decade and 6 per cent in the fifth decade. In his series, the recovery rate diminished with the age. In Martland's¹³ series of 54 cases of sudden death due to subarachnoid hemorrhage, age was not a significant factor.

SEX

Although in this series women were more commonly victims of spontaneous subarachnoid hemorrhage than were men (75:55), death favored neither sex. Forty-eight per cent of the women and 51 per cent of the men died of the disease.

STATE OF HEALTH PRIOR TO SUBARACHNOID HEMORRHAGE

No history of any previous constitutional disease was obtained in 51 of the 130 cases. The records of the other patients revealed various disorders as summarized on table 2.

Vascular Disorders.—Thirteen (21 per cent) of the patients who recovered and 16 (24 per cent) of those who died had a history of "heart trouble" or findings indicative of chronic vascular disease, hypertension, or arteriosclerosis. Blood pressure at the time of admission was elevated in 21 of the 63 survivors (32 per cent) and in 26 of the 67 who died (39 per cent). As Richardson and Hyland⁵ pointed out, during the acute phase of the illness patients may show elevations of the blood pressure which subside as their condition improves. Magee⁶ found that in 52 patients of 63 in whom blood pressure readings were made the pressure was below 150 mm. of mercury. This was at a time when the spinal fluid pressure was increased.

Headache.—Chronic headaches prior to the hemorrhage were complained of by 7 (11 per cent) of the patients who recovered and by 7 (10 per cent) of those who died. From the description of the headaches

* One patient in either or both groups had suffered from prostatic obstruction, deafness and tinnitus, alcoholism, attacks of syncope, recent head injury, mental disorder, Raynaud's disease, previous "stroke," acute infection of the upper respiratory tract, Bell's palsy and pulsating exophthalmos.

muscular exertion appeared to precipitate the onset in only about 18 per cent. They concluded that the rupture of an aneurysmal sac is usually a gradual process of stretching and hemorrhagic dissection and in only a few cases is the tear culminated by a sudden increase in blood pressure due to violent muscular effort. Only 8 per cent claimed an isolated incident as a precipitating factor in Magee's⁶ series. In 90 per cent there was no history of physical exertion, and in 28 per cent of his patients there was a special accent on rest, the patient being seized with the hemorrhage while in bed or in a chair. In his 50 cases of recurrence, more than two thirds occurred while the patients were in bed or in a quiet hospital environment. He concluded, "As between rest and effort this series suggests that the former deserves the greatest share of blame." Martland¹³ found that development of aneurysms was not related to trauma but that rupture might be precipitated by trauma or by physical exertion. He emphasized that trauma rarely was a cause, the same catastrophe occurring while asleep. Exertions which cause elevation of intracranial blood pressure, such as straining at stool, lacing the shoes, sexual intercourse or sneezing were of more importance than major trauma. Magee, on the other hand, made a series of sixty-three blood pressure readings while spinal fluid pressure was

13. Martland, H. S.: Spontaneous Subarachnoid Hemorrhage and Congenital "Berry" Aneurysms of the Circle of Willis, *Am. J. Surg.* 42: 10-19, 1939.

and the findings at postmortem examinations, no satisfactory explanation of this complaint was discovered.

Periodic headaches or migraine were complained of by 4 patients who recovered and by 1 who died. Dunning¹⁴ made an analysis of the association of migraine and aneurysm and found them associated occasionally.

Fig. 4.—Proportion and fate of patients admitted in primary and secondary attacks of bleeding.

Since changes in caliber of cranial blood vessels are known to occur during attacks of migraine, he felt that this was probably a predisposing factor to hemorrhage and occlusion in the presence of an aneurysm. From the analysis of the records in our cases, migraine and other types of periodic headache must be listed together, since the histories were not sufficiently specific to allow differentiation. No case of true ophthalmoplegic migraine was found in the series.

Strauss and Tarachow¹⁵ attached great prognostic significance to the "underlying" or associated pathologic processes accompanying subarachnoid hemorrhage. They found that subarachnoid hemorrhage might occur in a variety of pathologic states and that the prognosis varied with the underlying or associated pathologic process. In 105 cases of subarachnoid hemorrhage, they found 39 patients with cardiorenal-vascular disease, of whom 14 died on the first admission. Of these, only 5 were examined at autopsy; 2 had aneurysms. In the other 3 no aneurysm was found, but, as mentioned before, failure to find an aneurysm does not eliminate the likelihood that the lesion is present. In their group of cases, moreover, are included 13 cases of clinically diagnosed brain tumor, 6 of subacute bacterial endocarditis, 5 of syphilis of the central nervous system, 4 of blood dyscrasias and 30 in which no clinical evidence of accompanying disease could be found. One may conclude that their series and ours are based on different criteria and that the results are not comparable.

No case of coarctation of the aorta was found among the cases examined at autopsy in this series. Baker and Shelden,¹⁶ Hearne,¹⁷ Walsh and King¹⁸ and

Woltman and Shelden¹⁹ have stressed the association of subarachnoid hemorrhage with coarctation and other lesions of the aorta. These associations are suggestive of the congenital origin of intracranial aneurysms.

In summary, our observations agree with those of Richardson and Hyland that hypertension was the only constitutional disorder that occurred with sufficient frequency to be regarded as more than incidental and that in the majority of cases there was no history of trauma, infection or other condition which could be regarded as a predisposing cause of the hemorrhage. In our series, however, hypertension was not an important factor in prognosis, since it was found in 21 per cent of patients who recovered and in 24 per cent of those who died. Nor did elevation of blood pressure on admission to the hospital seem significant in prognosis, being present in 32 per cent of patients who recovered and in 39 per cent of those who died.

HOSPITAL COURSE

Previous Attacks.—Ninety-eight patients in this series were admitted in their initial attacks of subarachnoid hemorrhage (fig. 4). Of these, 44 (45 per cent) died and 54 (55 per cent) recovered. Thirty-two patients had experienced previous attacks. Twenty-three (72 per cent) of these died and 9 (28 per cent) recovered. A patient who entered the hospital in his initial attack of hemorrhage had a little better than an even chance (55 per cent to 45 per cent) of recovery. One entering with a recurrent attack had only a 28 per cent chance of recovery.

Multiple Attacks.—Instances in which fresh bleeding occurred after initial improvement were classed as "multiple attacks." This factor has not been evaluated in most other reports in the literature, the exacerbation being considered a part of the initial process, since the vessel obviously does not have time to heal between the episodes.

Fig. 5.—Mortality in relation to attacks of bleeding in the hospital.

Sixty-one patients in this series suffered multiple attacks of bleeding in the hospital, while 68 experienced only the one episode (fig. 5). Of the 68 patients who suffered a single episode of bleeding, 42 (62 per cent) recovered and 26 (38 per cent) died. Of the 61 who had multiple episodes of bleeding, 21 (34.5 per cent)

recovered and 40 (65.5 per cent) died. The patients with multiple bleeding episodes had only about half the chance of recovery of those with a single episode. This probably means that the patient with the uncomplicated hospital course had a vascular defect that healed more readily than those bleeding repeatedly.

TABLE 3.—Comparison of Most Frequent Neurologic Signs in Fatal Cases and in Cases in Which There Was Recovery

	Recovered (61)	Died (61)
A. Hemiplegia.....	11	14
B. Monoplegia.....	5	1
C. Ocular palsy.....	25	25
D. Other cranial nerve palsies.....	14	6
E. Mental disturbances.....	30	56
F. Convulsions.....	4	14
1. General.....	4	9
2. Focal.....	0	5

Unconsciousness.—Unconsciousness during the course of the illness occurred in 13 (21 per cent) of patients who recovered and in 29 (42 per cent) of those who died. The patient who suffered loss of consciousness during the course of the illness had only half the chance of survival of those who did not.

PHYSICAL SIGNS

Physical signs in these patients are due to those secondary to the presence of blood in the subarachnoid space and localizing signs due to organic central nervous system damage.

1. **Signs Due to Subarachnoid Hemorrhage.**—Stiff neck and Kernig's signs were found in practically all cases either immediately or after a few hours. Sluggishly reacting pupils and diminished tendon reflexes were found frequently. Babinski's sign occurred without paralysis occasionally. Papilledema was found in 14 per cent of cases but never before the seventh day of the illness. In records in which a note was made of the ophthalmoscopic findings, fundus hemorrhage was found in 10 per cent of cases, usually associated with papilledema. In only 6 cases were found the subhyaloid hemorrhages considered typical of subarachnoid hemorrhage.

2. **Localizing Phenomena.**—Signs of damage to the central nervous system may be caused by the extension of the hemorrhage itself into the brain substance or by changes due to anoxia secondary to the bleeding lesion. Table 3 presents the localizing phenomena found in the 61 patients who recovered and in 61 who died.

TABLE 4.—Comparison of This Series with Two Series Previously Reported

	New York Hospital [†]	Magee ^a	Buffalo General Hospital
Patients.....	46	150	130
Died, first attack.....	11%	35%	39.9%
Recurrent attacks.....	52%	37%	35.4%
Died in recurrence.....	22%	21%	28.5%
Survived.....	67%	44%	56.9%*

* The fate of 1 survivor is not known. If alive, the figure here would be 37.6 per cent.

It may be concluded that physical signs give evidence of damage to the brain accompanying subarachnoid hemorrhage, but in this series they were not helpful in prognosis.

SUMMARY OF IMMEDIATE PROGNOSIS

Of 130 patients with subarachnoid hemorrhage, 67 (51.5 per cent) died and 63 (48.5 per cent) recovered to leave the hospital.

Age was not a significant factor in prognosis, the average ages of those who recovered and those who died being essentially the same. Hypertension and other vascular diseases were as prevalent among those who recovered as among those who died.

Of 32 patients who suffered a previous attack of subarachnoid hemorrhage, 72 per cent died. Of 98 patients who entered the hospital in their initial attack, 42 per cent died.

During their hospital course 68 patients had a single episode of bleeding, and 62 per cent of these recovered. Sixty-one patients had multiple attacks of bleeding in the hospital, and of these only 34.5 per cent recovered.

Forty-two patients were unconscious during the illness, and of these 29 (69 per cent) died and 13 (31 per cent) recovered.

The occurrence of mental disturbances and convulsions during hospital course was accompanied by an increase in the mortality rate.

LATE PROGNOSIS

Magee ^a recorded the fate of 150 patients suffering from subarachnoid hemorrhage; 52 died and 98 lived. Of the 98 survivors, 50 suffered recurrence, from which 32 died and 18 lived. Eighty-four of the original

Fig. 6.—Present status of 130 patients with spontaneous subarachnoid hemorrhage.

150 patients died eventually of the disease and 66 lived. Twenty-one of the 66 remained so severely crippled as to be permanently disabled. Of the 150 patients, then, only 45 (35 per cent) survived in satisfactory condition.

Wolf, Goodell and Wolff [†] analyzed a group of 46 patients followed at the New York Hospital and compared their results with those of Magee. To their result, ours have been added in table 4. Many obscure or apparently minor factors influence recovery and fatality in reported series. Wolf and his co-workers attributed their more favorable figures to the fact that the New York Hospital had no ambulance service! Patients having severe primary attacks died at home or entered other hospitals, leaving a larger number to survive and also to suffer subsequent fatal attacks.

Follow-Up Studies (fig. 6).—Of our 130 patients, 67 (51.5 per cent) died in the hospital and 63 (48.5 per cent) survived. Of the 63 who survived, 62 have been traced, and their present status has been determined either by personal contact or through their physicians. Of the 62, 48 (77.4 per cent) have survived and 14 (23.2 per cent) have died since discharge.

Three others have died of unrelated diseases sufficiently long after discharge to have demonstrated good recovery.

Deaths Since Discharge.—Fourteen patients have died as the result of vascular accidents; 5 within two weeks of discharge from the hospital, presumably from unhealed original lesions. All 5 had left the hospital against advice, one suffering a fresh hemorrhage in the ambulance on the way home. Four had been severely crippled by damage to the brain. Duration of bed rest following their hemorrhages had ranged from four to thirty days, an average of fifteen days. Three of the 5 had suffered multiple attacks of bleeding in the hospital. In 4 of the 5, the onset of the clinical picture had been with unconsciousness.

The remaining 9 lived after discharge from the hospital for periods varying from one month to eight years (one, one, three, six, eight and ten months and three, five and eight years). Of these, 3 showed neurologic residuals of their accidents at the time of discharge. Duration of bed rest following their accidents had ranged from sixteen to forty-two days, an average of 28.5 days. Only 2 of these patients had suffered multiple attacks of bleeding in the hospital. In 3 of these patients the onset of the original hemorrhage had been accompanied by unconsciousness and in 1 by hemiplegia.

Survivors.—Of the original 130 patients, 48 (36.9 per cent) are known to have survived the disease. Twenty-one of these consider themselves completely recovered. Thirteen others are back at work, suffering neurologic handicaps, and 11 are so severely handicapped as to be crippled. Three subsequently died of unrelated causes. Of the original 130 patients only 21 (16.9 per cent) may be considered to have survived intact up to the present time. Since 37 (28.5 per cent) have suffered their attacks within the past five years, this figure may be expected to diminish with the passage of time.

SUMMARY

Analysis was made of data obtained from the records of 130 patients entering the hospital with spontaneous subarachnoid hemorrhage.

In 44 of 47 proved cases hemorrhage was caused by ruptured aneurysms (93.6 per cent). In 23 of 44 fatal cases concomitant intracerebral hematomas were found (52 per cent).

Factors unfavorably affecting prognosis for the presenting attack were: previous attacks, multiple hemorrhages in the hospital, mental disturbances, unconsciousness and convulsions.

Of the 130 patients, 67 (51.5 per cent) died in the hospital. Sixty-three patients (48.5 per cent) survived and 62 of them have been followed: 17 have died and 45 live. Only 21 (16.9 per cent) of the original 130 are considered recovered to date, 13 are able to work with neurologic handicaps and 11 are crippled.

ABSTRACT OF DISCUSSION

DR. J. C. RICHARDSON, Toronto, Canada: At the Toronto General Hospital we have been interested in the types of intracerebral hemorrhage produced by aneurysms. Dr. Hamby has encountered such hemorrhages in 52 per cent of his cases, a percentage similar to ours. His demonstration of aneurysms in cases of intracerebral hematoma treated surgically is important. It seems likely that aneurysms are the commonest cause of such spontaneous intracerebral hemorrhages in nonhypertensive patients. Most commonly, aneurysms produce intracerebral bleeding, coincident with or shortly after a subarachnoid hemorrhage, but one occasionally sees a predominantly intracerebral

hemorrhage with minimal subarachnoid leakage. We had a verified case of an aneurysm which caused a purely intracerebral hemorrhage with no blood in the cerebrospinal fluid. Hemorrhages of the temporal lobe produce visual field defects and aphasia. Not uncommonly there is extension of bleeding into the capsular region with hemiplegia. The clinical syndrome of hemorrhage of the frontal lobe from an anterior cerebral aneurysm is featured by striking apathy, acute dementia and often a grasp reflex. We have confirmed Dr. Hamby's observation that these intracerebral hemorrhages, along with subarachnoid hemorrhage, do not materially lower the patient's chance of survival. What is the prognosis in the case of a person having a second hemorrhage from an aneurysm, some months or years after a first attack? Dr. Hamby finds a much higher mortality when there have been previous hemorrhages. In our series the experience has been rather different, suggesting that there is no greater danger of death in a late second or third hemorrhage than in the first. It is of great importance that recurrent attacks of bleeding may occur with added dangers in the first few weeks after the original subarachnoid hemorrhage. The danger peak is between two and four weeks. In Toronto we seem to have had a rather smaller incidence of these earlier relapses. Reviewing 124 cases recently, I found that only 26 had had recurrences of bleeding in the three months after the first hemorrhage, and 15 of these cases were fatal. There was 52 per cent mortality in the whole group. I do think that absolute bed rest for a minimum of six weeks and usually two months is important in preventing these early relapses. We are all interested in the eventual outcome of patients who have survived a subarachnoid hemorrhage. The over-all picture, including the high toll of death from initial hemorrhage and early recurrences, is not a bright one. On the other hand, the outlook for those patients who have survived the first few months after a hemorrhage is not too bad. I think that the figures of Hamby, as well as those of Magee and of Wolf, Goodell and Wolff, all give that same impression.

DR. I. S. WEICHSER, New York: The paper of Dr. Hamby gives me an opportunity to say a word on the diagnosis and treatment of subarachnoid hemorrhage. The former is fairly easy; the second is called conservative, which is no treatment at all. Generally we speculate about aneurysms and their location. With the introduction of "diodrast" (iodopyracet) by Dr. Gross, a safe method of outlining vascular anomalies can be used both for diagnosis and treatment. The clinical experiences of Dr. Hamby, in the main, parallel our own at the Mount Sinai Hospital. One word about psychoses in subarachnoid hemorrhage: The Korsakoff syndrome occurs in subarachnoid hemorrhage, the only condition, as far as I know, other than alcoholism with avitaminosis. In our experience, hemorrhages caused by aneurysms are frequently fatal in the first or second episode, whereas patients who have repeated attacks are more likely to have other vascular anomalies. We have one instance in which there were fourteen recurrences. Three or four recurrences in the same patient were not uncommon. Patients with such anomalies can be treated more successfully than those with aneurysms. The common carotid artery was tied in 2 instances; in 1 it was ligated intracranially. The reason why the common carotid artery was ligated is that the circulation is cut down only by about 50 per cent and the danger of hemiplegia or convulsions is practically eliminated. We have not had fatalities following ligation of the common carotid artery. In one patient who had several recurrences, the common carotid artery was tied in 1943; she has had no attacks since. Arteriography is a simple and safe procedure. It is a guide to diagnosis, as to the type of lesion and its localization. It is an indication for treatment. Patients who have repeated attacks of subarachnoid hemorrhage are more likely to have vascular anomalies. Recurrences may be prevented in those patients in whom arteriography leads to the successful ligation of vessels either extracranially or intracranially.

DR. RUDOLPH JAEGER, Philadelphia: This beautiful presentation of Dr. Hamby, of course, rightfully emphasizes the fatal nature of this disease, which I am afraid in the past has not been sufficiently emphasized as a hazardous disorder. There has been a tendency to temporize with these cases, not to treat them actively, and to wait until another hemorrhage occurs, and

we know now that this is not the proper attitude to take toward them. The diagnosis as to the cause of spontaneous subarachnoid hemorrhage is a challenge to the neurosurgeons. As has been said, the diagnosis of subarachnoid hemorrhage is easy, but the point of vascular rupture may be difficult to find. We feel that these lesions should be approached surgically when there are definite localizing neurologic signs. The problem then is not so difficult. But, in these cases in which we simply have the general signs of spontaneous subarachnoid hemorrhage with blood in the spinal fluid, we then have the added problem of localizing the causative lesion. Certainly, the surgeon now must solve this problem, as only he can make the precise diagnosis. Angiography seems at present to be the answer to an accurate diagnosis of these lesions. This procedure has not been fully explored. We feel that it is the answer if we can go ahead and develop it to the point where it is accurate and safe. We are extremely cautious with angiography at present, and only time will tell its exact worth. It seems that we are fast approaching the point where aneurysmal lesions will practically all be operated on and where we can locate them by our diagnostic methods. We ultimately should be able to locate each of these aneurysms which has ruptured and treat it directly. Experience has shown that the surgical mortality need not be prohibitive. Single ligation of the carotid artery in the neck will not cure aneurysms of the circle of Willis. The aneurysm must be attacked directly and tied off. This is the only specific treatment for an intracranial aneurysm.

MODERN MEDICAL AND SURGICAL TREATMENT OF PEPTIC ULCER

An Appraisal

RUSSELL S. BOLES, M.D.
Philadelphia

In 1793 Matthew Baillie of London described the morbid anatomy and symptoms of ulcer of the stomach. The first reference in medical literature to ulcer of the duodenum appeared in 1817 in the *London Medico-Chirurgical Transactions*. It consisted of a report by Mr. Travers of 2 cases of perforation. In 1887 Bucquoz, following a suggestion made by Abercrombie some years previously, reported 5 cases of duodenal ulcer based on the history alone, 1 of which was verified by autopsy. The principles of the medical treatment of ulcer employed today were first laid down by Cruveilhier and others nearly one hundred years ago, and the first successful operation for perforated ulcer was reported in 1894 by H. P. Dean.

So it seems that this lesion has been known to us for one hundred and fifty odd years, and for some fifty years it has been subject to the surgeon's scalpel. All of which would be merely of historical interest were it not for the depressing fact that during these years we have not learned its cause and still grope about for its cure. When it has been estimated that 1,500,000 persons in the United States past 30 years of age are affected by peptic ulcer during a period of ten years (Ivy) and that 10,000 persons die each year from the disease and its complications (Wangensteen), we are confronted with a serious state of affairs. Such being the case, it is time to inquire diligently into the reasons for this predicament.

I shall begin such an inquiry by briefly discussing a few of the more important aspects concerning the patho-

genesis of ulcer, since it follows that success in the treatment of any disorder is dependent on an understanding of its cause.

PATHOGENESIS OF ULCER

An immediate need is to abolish the term "peptic ulcer" that serves as a diagnosis for the condition. There is no proof whatever that peptic ulcer is due to pepsin; furthermore, the ulcer itself is no more the disease than an ulcer on the toe is diabetes, arteriosclerosis or Buerger's disease. For reasons that I shall presently mention, a more accurate and descriptive term would be "neurocirculatory ulcer." When we begin to look on the ulcer as the complication of a systemic disorder, we shall have made our first step toward a solution of this problem. Obviously, this will be difficult to do as long as we persist in focusing our attention on the local lesion in the stomach and duodenum. Such a misconception of the disease may be attributed to what I believe is the erroneous assumption that peptic ulcer is primarily due to an increase of the acid-pepsin factor of the gastric juice and that control of this factor is the main essential for healing. Nearly fifty years ago Cohnheim said that hyperchlorhydria as such never causes peptic ulcer. He believed, on the contrary, that ulcer caused the hyperchlorhydria, the latter being the result of retention of food and irritation of the gastric glands due to pylorospasm. In 1926 Eggleston was of the opinion that hyperchlorhydria resulted from pylorospasm incident to active ulceration. Necheles expressed the belief that increased secretion of acid in animals with ulcers is due to the local lesion and that acidity does not go up until an ulcer is formed. In further support of these views is the statement of Cowgill that retention of food in the stomach, caused by pylorospasm or pyloric stenosis, augments the gastric and intestinal phases of gastric secretion. As long ago as 1912 Moynihan said that the idea is deep rooted that the symptoms of ulcer are always due to an excessive acidity in the gastric juice, but "there was no foundation in fact for this venerable fallacy." If it was a venerable fallacy in Moynihan's day, it has become a fixed obsession since his time.

I am well aware of the vast amount of experimental work that has been done that incriminates acid as the cause of ulcer. I furthermore appreciate that ulcer does not occur in achlorhydric stomachs. Despite this, it is difficult to assume that a fixed relationship exists between the degree of acid secretion and ulcer, as we know that many persons with excessively high acid secretion do not have ulcer and that others with normal or diminished secretion do have it. Also, while it is a well established fact that measures designed to diminish secretion of acid provide comfort for the patient, it must be remembered that those same measures allay pylorospasm and that this may account for their effectiveness. It is common knowledge, furthermore, that patients with ulcer may be comfortable despite wide fluctuations in their gastric acidity and without the use of antacid drugs. There is much to suggest, therefore, that acid does not play the primary role in the pathogenesis of ulcer and that it is time to lay less emphasis on the importance of the acid-pepsin factor and devote the time and talents expended in pursuing this phase of production of ulcer to broader and more fundamental aspects. Such action would be justified for the sound reason that all the medical and surgical methods of treating ulcer, past and present, have been designed to neutralize or abolish secretion of

Read before the Section on Internal Medicine at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

Because of lack of space this article has been abbreviated in *THE JOURNAL* by omission of the bibliography. The complete paper will be found in the author's reprints, which the author will be pleased to send on request.

acid, and in large measure they have failed. Who can say he has cured an ulcer when the familiar scars seen at operation and necropsy attest so well that it has cured itself! The time has arrived for more philosophy and less technic—to use the words of Ryle. I would add to this a plea for a degree of clinical research that will keep pace, at least, with the intensive experimental research which we have witnessed for so many years. In my humble opinion, the solution of the problem of ulcer will not be found in the belly of the dog any more than will the cause of hypertension, arteriosclerosis or heart disease.

How then shall we approach the broader and more fundamental aspects of ulcer to which I have alluded and on which a rational plan of treatment must depend? I would suggest, in the manner expressed by John A. Ryle in outlining the purposes of the Institute of Social Medicine at Oxford; i. e., "To investigate the influence of social, genetic, environmental and domestic factors on the incidence of human disease and disability." Ryle went on to point out what I believe is one of the great faults of our profession today:

Investigation to the limit, mainly by objective methods and often with too little said to or done for the patient during or after the tedious process, has been the prevailing trend, especially in the case of the more chronic or seemingly more obscure varieties of disorder and disease. More and more accurate assessments of local pathology, with the help of more and more colleagues and instruments, and less and less intimate understanding of the patient as a whole man or woman with a home and anxieties and economic problems and a past and a future and a job to be held or lost, have become the order of the day.

I would attribute the highly unsatisfactory results of the medical and surgical treatment of ulcer today to our failure to recognize the need for the kind of investigation to which Dr. Ryle referred.

I will mention briefly a few of the factors that I believe are related specifically to ulcer. The first is the constitutional background. Is there a bonafide "ulcer diathesis" that renders certain types of persons, because of psychologic and physical characteristics, more susceptible to ulcer? Ryle and Hurst and Stewart, who have been among the soundest contributors to this subject, stressed the importance of a familial influence. Among the most recent observations on this aspect of the disease are those of Gainsborough and Slater, reporting from London, England, which suggest that a hereditary constitutional factor appears to predispose to the condition. Edwards and Copeman also reported a family history of ulcer in more than one half of 139 cases studied.

The next aspect of the disease that I would consider of primary importance is the vascular. Clinical and autopsy records indicate that the incidence of duodenal ulcer has increased in the past twenty-five years, according to Ihre and Müller. It is of interest to note that the trend corresponds to an increasing incidence of vascular disease. From 1921 to 1935 inclusive, there was a considerable increase in the mortality from duodenal ulcer in males 1 to 74 years of age in the United States, according to the statistics of the Metropolitan Life Insurance Company (Dublin and Lotka). The increase, as might be expected, was greater among men than women, the latter enjoying a relative immunity to duodenal ulcer. The mortality from gastric ulcer increased from 4.2 per hundred thousand in 1920 to 7.2 in 1935. From 1930 to 1934 inclusive, the mor-

tality among white men was about five times as great as among white women. There appeared no satisfactory explanation for a consistent downward trend in mortality from ulcer of the stomach among white women. In contrasting these figures to those on disease of the coronary arteries, one notes that from 1930 to 1934 inclusive, the mortality of the latter rose from 7.9 per hundred thousand to 27.4, an increase of nearly three and one-half times in four years.

The crux of the ulcer problem which should be thoroughly investigated is the matter of cell resistance on the part of the gastric mucosa. At present it would seem that cellular resistance depends on the state of the circulation in the stomach and on the chemical composition of the blood reaching the cell. Boles, Riggs, and Griffiths demonstrated that a significant influence was exerted in the formation of ulcer by chronic circulatory insufficiency in the deeper layers of the stomach—the insufficiency being established through quantitative, qualitative or vasomotor disturbances in the circulatory system. Necheles has corroborated these observations. The fact that disease of the vessels at the site of an ulcer cannot always be demonstrated need not be surprising, especially in younger persons, because in most cases the reduced blood flow to the ulcer is the result of spasm of the vessels. It occasions no surprise when proportionate disease of the coronary arteries cannot be demonstrated in certain cases of angina pectoris. That ulcer does not follow ligation of the vessels to the stomach may be explained by the fact that cellular resistance does not seem to be lost until chronic inflammatory changes have become established in the deeper layers of the stomach wall. The studies of Dodds and of Nedzel demonstrated that local areas of anemia in the gastric mucosa, resulting from chronic arterial spasm produced by the injections of epinephrine or "pitressin," rendered it susceptible to the action of the acid-pepsin factor in the gastric juice. Babkin expressed the opinion that the devitalizing mechanism is one of vasodilation and stasis.

Bachrach, Grossman and Ivy have recently demonstrated that autodigestion of the stomach does not occur if the circulation to the mucosa is adequate and if the metabolic and nutritional condition of the patient is sufficient to maintain the tolerance of the cells to acid-pepsin secretion and to provide for their regeneration and proliferation and for the secretion of mucus. The belief was expressed by Roth and Ivy "that the proteolytic action of acid and pepsin secretion upon a gastric mucosa rendered more susceptible to the ulcerative process by the vascular and 'cellular' changes induced by caffeine, results in the development of an ulcer." The effect of emotional disturbances on the circulation of the stomach leading to mucosal erosion and hemorrhages have been graphically described by Wolf and Wolff. The recent observations of Aycock and Hendrick, showing that venous thrombosis occurs more frequently in the spring and fall months of the year and that it is less prevalent in winterless areas, are of interest because of the similarity in behavior to ulcer. Since ulcer most frequently occurs in that part of the stomach and duodenum in which there is a rich supply of nerves and blood vessels and since the influence of the one over the other may diminish cellular resistance, the name "neurocirculatory" ulcer of the stomach or the duodenum is suggested.

That tobacco is instrumental in production of ulcer and especially in the prevention of healing is agreed by most students of the subject. The ill effects of tobacco may logically be attributed to its action on the end vessels in the stomach and duodenum, as it is known to be a potent vasoconstrictor of peripheral vessels and to reduce their blood flow (Stewart). For this reason it is recognized as a major factor in the production and healing of such ulcers as are seen in thromboangiitis obliterans (Silbert) and arteriosclerosis obliterans in diabetes (Weinroth and Herzstein). Indeed there is much else in common in the behavior of these ulcers and peptic ulcer that suggests a similar vascular origin. That the ill effects of tobacco are due to its action on the circulation rather than on the secretion of the stomach is borne out by the experimental work of Schnedorf and Ivy. In the opinion of Goodman and Gilman the acidity of the gastric contents is not influenced by cigarette smoking in smokers with peptic ulcer. These authors suggested that the gastrointestinal complaints caused by the use of tobacco may be secondary to cardiovascular disturbances. In this connection the observations of Jamieson, Willingworth and Scott are of interest, though they occasion no surprise. They found that excessive cigarette smoking was associated with mild symptoms. I would presume to quote to Jamieson, Willingworth and Scott the words of Richard le Gallienne: "Behind the times I know I am, but what is a tired man to do? I light my pipe and read Charles Lamb." Such a man, as we might suspect, does not have ulcer!

The matter of sex and the reasons for the difference in behavior of duodenal and gastric ulcers are matters that require investigation, as they enter so strongly into any consideration of treatment. There may be some merit in wondering whether gastric and duodenal ulcer are one and the same lesion and whether their treatment should be similar. When one considers that duodenal ulcer occurs so much more frequently in men than women, that it occurs more frequently than benign gastric ulcer, that it does not heal so spontaneously as the latter, that the mortality of duodenal ulcer is increasing in men, that the mortality of gastric ulcer is stationary or declining in women, that the two ulcers exhibit differences in the frequency of such complications as hemorrhage and perforation and differences in response to surgical treatment and, finally, that gastric ulcer is frequently malignant while duodenal ulcer rarely is so, one realizes that too much emphasis cannot be placed on the importance of greater accuracy in diagnosis so that clinical, operative and necropsy findings can be better reconciled.

The immediate results of the treatment of ulcer, be it medical or surgical, must take into consideration the effect of climate and season. Significant changes in the chemical composition of the blood and in some cardiovascular reactions in peptic ulcer were observed by Riggs, Boles, Reinhold and Shore in patients studied throughout a one year period. It is well known that peptic ulcers are notoriously troublesome in the spring and fall months. In addition to reactivation, the complication of hemorrhage, in my experience, is more common in these months. Ulcers subside in summer and make their appearance less frequently in uniformly warm climates. This may logically be due to the absence of alterations in the bodily circulation which

are induced by abrupt changes in the climate and seasons (LeLangen). Finally, an appraisal of treatment cannot ignore the natural remissions of the disease which may extend over a period of weeks, months or even years. Such are some of the basic problems that must be evaluated in this disease before we can properly appraise any method of treatment.

TREATMENT

I do not believe that we should claim credit for permanent cures of gastric and duodenal ulcer, although we can do much to promote healing and prevent recurrences and complications. How best may this be done, by surgical or medical means? Let us consider the record.

The consensus of opinion is that peptic ulcer is a medical problem and that operations should be reserved for the familiar complications of perforation, hemorrhage, obstruction and so-called intractability. The trend from surgical to medical treatment has taken place in a conspicuous way during the past twenty-five years. At the Mayo Clinic (Eusterman), the operations for duodenal ulcer dropped from 38 per cent to 13 per cent during this period. During the past eighteen years, the surgical treatment for gastric ulcer rose slightly from 50 per cent to 62 per cent, the increase presumably being due to the assumption that most gastric ulcers should be regarded as malignant or potentially so. At the Lahey Clinic (Lahey and Marshall), only 6.6 per cent of 6,550 patients with duodenal ulcer were operated on and 18 per cent of 450 patients with gastric ulcer. At the Peter Bent Brigham Hospital in Boston, Zollinger reported that in the period from 1932 to 1937 only 7 per cent of 1,200 patients with peptic ulcer were treated surgically and 93 per cent medically.

Medical Methods.—The shift from surgical to medical management of ulcer during the past twenty-five years may be attributed to the fact that while medicine may not accomplish much good, it at least is productive of little harm. It has been estimated that the results of the medical treatment of ulcer are unsatisfactory in 40 per cent to 60 per cent of cases (Krarup). Raimondi and Collen gave an incidence of recurrence of 83 per cent in 151 patients treated for two years. The unsatisfactory results of medical treatment can be charged, I believe, to preoccupation with the surgeon's objective; i. e., correction of the chemical environment of the lesion. The medical control of ulcer and its attendant acid secretion is attempted by rest, diet, no alcohol, coffee or tobacco, and an injunction to lead a calm and imperturbable life. While acidity may be controlled by these means, healing and recovery would appear to be the result primarily of release of pylorospasm and vascular spasm in the gastric vessels. The rewards, if such they be, of such a regimen are inactivation and healing of the ulcer, provided it has not become scarred and indurated from years of abuse.

Extracts: Enterogastrone concentrate is obtained from the small intestine of hogs. It has been developed and is being used clinically by Ivy and his group. It inhibits gastric secretion and motility. Its effect on cellular resistance is being studied. If it is shown to increase cellular resistance, it should contribute to the prevention and healing of ulcer. Ivy reported (1943) a group of 26 patients who received injections of

enterogastrone six times a week for three to twelve months, in whom the results have been very gratifying. The unfortunate disadvantage of such treatment is the necessity for almost daily injections over a period of months. The length of time a remission continues after a course of treatment with enterogastrone has not been determined, though it appears to last for some time, as has been demonstrated by Greengard and his colleagues, in a therapeutic trial on 43 Mann-Williamson dogs and 58 patients suffering from proved peptic ulcer. It is to be hoped that the oral preparation which Ivy is using may prove satisfactory, since the parenteral treatment as outlined at present is impractical.

Sandweiss and his co-workers some time ago isolated an antiulcer principle in human urine (urogastrone) which acted as a depressant of gastric secretion. Later, they observed that the beneficial effect on ulcer was probably due to a substance they called anthelone, that appeared to increase cellular resistance and thereby provided immunization against ulcer. If this work is sustained, a definite contribution to the management of ulcer may be expected.

The employment of extracts, hormones or other substances by injection for the treatment of ulcer is analogous to the use of insulin for diabetes and liver extract for primary anemia. Any benefit that may accrue from their use is probably of a temporary nature, and if it is to be maintained, courses of injections or oral therapy would have to be given indefinitely at intervals yet to be determined.

Intragastric Drip: This method of treatment, first described by Winkelstein, is a troublesome one at times and is not well received by all patients. It is undoubtedly effective in reducing acid secretion and is particularly well suited to refractory ulcers with a high continuous nocturnal secretion, and especially when pyloric obstruction is present.

Mucin: Mucin, as originally used by Fogelson and Atkinson, offered some promise in the treatment of ulcer because of its protective and antacid properties. Alone it lost favor, but at present it is being combined with neutral antacids and may prove helpful as a supplement in treatment.

Protein Hydrolysates: I do not believe that the various protein hydrolysates and amino acids exert any specific influence on ulcer; as supplements to the diet, they are useful. The necessity for them was shown in the studies on the chemical composition of the blood in patients having ulcer by Riggs, Reinhold, Shore and myself. Co Tui and co-workers demonstrated that protein hydrolysate therapy promptly inactivated ulcer, but did not insure against any recurrence with the patient on his regular diet.

Anion Exchange Resins: An interesting addition to the medical treatment of ulcer is the use of the anion exchange resins as described by Spears and Pfeiffer. These substances qualify as satisfactory antacids and inhibitors of peptic activity and as such should prove helpful in certain cases with a normally high and persistent acid secretion.

Surgical Methods.—First of the surgical attacks on ulcer was gastroenterostomy. It was designed to neutralize gastric acidity and thereby cure the ulcer. It was heralded as a cure in 90 per cent of cases by the surgical masters of the day. Its abysmal failure because of recurrent and marginal ulcers needs no

recounting at this time. Despite its shortcomings, it still serves a useful purpose in certain cases of pyloric obstruction in which other more radical procedures are inadvisable.

In the wake of gastroenterostomy there followed the various modifications of resection of the stomach. The purpose here was the partial or complete elimination of the acid-secreting portion of the stomach, the doctrine of "no acid, no ulcer" being tenaciously maintained. It might have been well had resection eliminated acid, but that such is not the case, especially for duodenal ulcer, is well recognized at this time. Heuer and his colleagues found that a reduction in acid secretion occurred after resection, depending on the extent of the resection. They concluded, however, that resection of any magnitude consistent with a reasonable mortality does not insure achlorhydria. Moreover, the clinical result of resection could not be correlated with a change in acidity since 90 per cent of their patients who had satisfactory results from the operation only 25 per cent had a reduction in acidity. They were of the opinion that if their observations were confirmed by others, the idea of insuring achlorhydria by larger and larger resections would appear to be of doubtful value. Klein, Aschner and Crohn, Kiefer and others have noted persistent acid secretion following resection, especially when done for duodenal ulcer. In connection with this matter of acidity before and after resection, it is absolutely essential in the interests of accuracy that histamine be used as a gastric stimulant; also that the precautions outlined by Kiefer be followed. He showed from a study of 141 patients that 68 per cent showed no free acid in a single forty-five minute specimen after an Ewald test meal following resection. However, when histamine was used, 16 out of 23 patients with a negative response to the Ewald meal were found to have free acid. He concluded that the secretion of free acid persists after subtotal gastrectomy in an appreciable number of cases, provided the stimulation is adequate. Jordan and Kiefer have emphasized the importance of securing fractional specimens for at least two hours with the patients lying flat in the supine position. I would emphasize the necessity of knowing that the tip of the tube is in the resected stomach if accurate values of acidity are to be obtained. Fluoroscopic examination may be necessary for this purpose. It can safely be said that a reduction of acidity may be expected to follow in most cases of resection for gastric ulcer. In the case of duodenal ulcer, however, the effect on acid secretion is problematic, to say the least.

That gastric resection is not the answer to the ulcer problem may be suspected from the widely varying statistics concerning its results and the diversity of opinion as to what the method and extent of the procedure should be.

The immediate mortality (2 to 22 per cent) has been so reduced in some circles that in skilful hands the operation itself under favorable circumstances carries little hazard. The morbidity on the other hand, as gaged by recurrences, jejunal ulcer, hemorrhage, perforation, loss of weight, anemia, postprandial symptoms and metabolic disorders, is well nigh impossible to appraise. The statistics in general covering these matters are not acceptable. Marshall and Schmidt, in a review of gastric surgery, stated that the composite figures show about 90 per cent satisfactory results from

subtotal gastrectomy for gastric and duodenal ulcer. This is about the same figure cited some years ago in behalf of gastroenterostomy. John Deaver, in citing such a figure, went on to say, "The ultimate results of gastroenterostomy have been most satisfactory." The statistics covering resection, furthermore, are incomplete in that they are not broken down as to age and sex of patient, location of the ulcer, total duration of the illness, associated disease, length of follow-up period, indications for the operation and precipitating causes of the complications. Such information covering at least a ten year period is essential if dependable conclusions are to be drawn. Ransom, in a study of the end results of subtotal gastrectomy for gastric ulcer, after a twenty year period of observation, reported excellent results in 62 per cent of 138 cases, good results in 30 per cent and poor results in 5 per cent. Verified jejunal ulcer was found in 3 per cent. By excellent was meant complete freedom from symptoms in 65 cases and very slight symptoms in 21 cases.

That the results of resection for duodenal ulcer are not as satisfactory as for gastric ulcer is indicated by the report of Kiefer, which shows an incidence of gastrojejunal ulcer of 11.4 per cent in a series of 173 cases. Rienhoff had to reoperate on 29 patients in a group of 255 who had had a conservative resection of duodenal ulcer, which indicated an incidence of 11.3 per cent recurrences. Of the survivors, 16.3 per cent continued to suffer pain. The possibility of gastrojejunal ulcer presents a formidable objection to resection for duodenal ulcer, and every effort possible should be made to avoid the operation in such cases.

Hemorrhage: Resection for hemorrhage appears to have little to offer in the general run of cases. The incidence of hemorrhage following resection varies from 10 to 30 per cent, which in most cases, of course, indicates recurrent ulcer or erosions. In other cases, hemorrhages recur because of associated cirrhosis of the liver, while in some a hemorrhagic diathesis may be present. If one is to judge from statistics, the choice of medical or surgical treatment for massive hemorrhage is a difficult one. Crohn reports a mortality, with medical treatment, of 1.8 per cent in patients under 45 years of age and of 9 per cent over 45 years of age. In other reports the figures ascend to 30 or more per cent, depending chiefly on the age of the patient. Surgical treatment affords similarly confusing statistics. Wilkinson and Tracey concluded that medical treatment is justified if the patient has had only one hemorrhage; if there have been two or more hemorrhages, they recommended radical resection as offering a better chance of prevention of further hemorrhage. They found that no form of treatment prevented recurrence of hemorrhage in 25 per cent of cases. Meyer, Sorter and Necheles reported that patients with bleeding peptic ulcer treated by resection had a total mortality rate of 22.2 per cent. Among those past 45 years of age with severe hemorrhage, the mortality rate was 42.8 per cent, while in those under 45 years of age the mortality rate was 30 per cent. Under conservative medical treatment, the mortality rate was 7.2 per cent irrespective of the age of the patient or the severity of the hemorrhage. Among those past 45, the mortality rate was 21 per cent, while in those under 45 there was no mortality. In general, it may be said that resection for

hemorrhage in a person under 45 is seldom justified, especially in the case of duodenal ulcer.

Analysis of the statistics available indicate that resection for benign gastric ulcer carries more promise of relief and protection from recurrence and jejunal ulcer than resection for duodenal ulcer. It carries the added protection of removing the potentially malignant lesion which is so difficult at times to diagnose with certainty before operation. Whether resection is for gastric or duodenal ulcer, the results are favored in proportion to the younger age of the patient and the shorter total duration of the illness. A second resection for any purpose may be expected to prove a disappointment, recurrence and hemorrhage following in its wake in a disappointing number of cases. Aside from the hazard of recurrent ulceration, there are not a few persons who suffer a number of unfavorable symptoms after resection. Berkman and Heck cited the experience of Custer, Butt and Waugh, who made a statistical study of two groups of cases in which partial gastrectomy was performed for peptic ulcer or a malignant lesion of the stomach. In the first group of 500 cases, the incidence of postprandial symptoms was 5.6 per cent, while in the second group of 112 cases, studied at a later date, the incidence was 12.5 per cent. Alvarez expressed the sad thought, after reviewing the literature on surgery for ulcer: If the published hospital mortality rates and percentages of recovery are so discouraging, what must the unpublished ones be? Concerning recurrences, jejunal ulcer and hemorrhage and the other liabilities mentioned, it is my impression that the figures are not improving as time goes on and that subtotal resection may be slowly but surely finding its level with gastroenterostomy.

Unless one is intrigued with the recent reports of nonoperative treatment of perforation as outlined by Taylor, there is little that need be said about this complication of ulcer. Taylor reported excellent results in certain cases of perforation by immediately emptying the stomach by means of an Ewald tube and keeping it empty by continued aspirations. Best results are attained if the stomach is relatively empty at the time of the operation. In skilful hands and under favorable circumstances, there would seem to be no objection to such management of perforation. Generally speaking, however, it would be well for the present to consider this complication a surgical emergency and operate within the first few hours of its occurrence. Eliason and Thigpen, on reviewing 70 cases of perforated peptic ulcer, found that the final end results of simple closure in 22 cases showed a higher percentage of permanent cures (86.4 per cent) than in 21 cases of closure plus primary gastroenterostomy (76.2 per cent). Simple closure seems to be the operation of choice for perforation. Radical surgery, if necessary, should be deferred until the patient can be properly studied and prepared.

Vagotomy: That all is not right with resection is attested by the interest attending the revival of the operation of vagotomy. This procedure essays to cure ulcer by reducing acidity, but in so doing seriously disrupts the secretory and motor mechanisms of the stomach. Dragstedt, Moore, Ruffin, Grimson, Schoen and Griswold, Walters, and others have contributed extensively to this subject, and it is the consensus that the operation is productive of both favorable and

unfavorable results. The favorable results that are emphasized are immediate relief of pain, reduction of acidity, healing of the ulcer and a paucity of recurrences. Such results bear close analysis. It should be pointed out, for instance, that the relief of pain, unless it is accompanied by healing of the ulcer, may become a dangerous liability. This is disclosed in the report of Walters, who called our attention to 2 fatalities from unsuspected perforation following vagotomy. It is already being observed that healing of the ulcer does not always take place and that disturbances of secretion and motility tend to return to normal. Also, at this time it is impossible to determine the probable incidence of recurrences. The unfavorable results of vagotomy are diminished or absent—motility of the stomach, dilatation and retention, epigastric fullness, nausea, vomiting and diarrhea. The dilatation and retention resulting from diminished motility may reach an alarming degree. According to Machella, Hodges and Lorber, it may be relieved by the subcutaneous or oral administration of "urecholine" (carbaminoylethyl-beta-methylcholine chloride). The diarrhea so far has not been troublesome. Its cause is unknown. It could be due to release of the intestinal tonus. This might also explain why so many persons are relieved of an obstinate type of constipation after the operation. An analogous situation exists in the case of the irritable colon which is best treated by antispasmodic measures. The diarrhea could hardly be of a bacterial nature, the result of reducing gastric acidity, as has been suggested, because it does not develop after certain resections of the stomach.

In order to make practical the operation of gastroenterostomy, whether it be one of necessity because of obstruction, or choice to prevent obstruction, resort to the subdiaphragmatic approach for vagotomy is being recommended by Bradley, despite the fact that it is maintained by Miller and Davis, on the basis of an anatomic study, that not all the fibers of the vagi can be reached by this method. Justification for inviting a predicament that requires this operation is difficult for me to understand in view of the disastrous jejunal ulcers and recurrences that followed in the wake of gastroenterostomy and dictated its abandonment some years ago. Undoubtedly, the subdiaphragmatic approach for vagotomy is to be desired, as it provides opportunity (1) to inspect the operative field and determine whether an ulcer is really present; (2) to examine its complicating features, and (3) to be able to supplement the vagotomy with whatever additional surgery may be required.

As far as secretion is concerned, it may be admitted that vagotomy appears to abolish the cephalic phase, but there is no proof that this is the more important phase of secretion. Also, it is not known that the vagus carries all the psychic stimuli from the midbrain. Furthermore, according to Cowgill, there is little doubt that the vagi carry secretory fibers to the pancreas, and stimulation of them results in a flow of pancreatic juice. As pancreatic juice is a factor in controlling hypersecretion and to such an extent that Ivy has made the suggestion that cases of gastric hypersecretion be studied for possible dysfunction of the pancreas, I cannot but wonder in what direction we are heading by sectioning the vagus and disturbing pancreatic

secretion. To confound confusion Cowgill has reminded us that "it is important to realize that the vagi are compound nerves and that there is evidence that all vagal fibers to the gastric musculature do not exert identical effects." That the central vegetative nervous system and its pathways play a significant role in the production of acute gastric ulcer was shown by Boles and Riggs in a pathologic study of 15 cases of acute gastric ulceration associated with primary intracerebral disease. In view of this, it is suggested that such a study be made of sections of the vagus nerves resected for ulcer.

Since it took ten years or more to uncover the ill effects of gastroenterostomy, obviously it is much too soon to appraise the eventual consequences of vagotomy. The direct effects, in the long run, on the stomach, liver, pancreas and small intestine, to say nothing of the indirect effects on the vascular system with the influence of the parasympathetic system obliterated, remain to be carefully evaluated. Of interest in this latter connection is the report by Blegen and Kintner of aggravation of gastric ulcer in 2 patients after dorsolumbar sympathectomy: one patient had repeated hemorrhages during convalescence from the operation and the second had a perforation from which he died, without pain. If a normal degree of gastric tone, motility and secretion could be accomplished by a partial or subtotal vagotomy, which may not be impossible, the operation would hold more promise of cure than the present total vagotomy. At the moment, I am of the opinion that the favorable results of vagotomy are far outweighed by the unfavorable. The possibilities from the operation may be surmised from the direful description given by Komarov, who observed its effects on 142 rats. As a result, he stated "that bilateral vagotomy interferes seriously with a number of essential visceral functions and from a physiological standpoint must be regarded as a grave operation." It may be too soon to form conclusions but not too soon to voice a protest to what has the appearance of becoming a mass experiment on human beings that is fraught with potentially serious and permanent disabilities.

If surgery seems inescapable for the complicated ulcer, subtotal resection, despite its shortcomings, offers a fair chance of relief for the patient, especially when it is done for gastric ulcer. I cannot agree with those who believe that all gastric ulcers should be subjected to resection because of the risk of cancer. Gastric scars are evidence that gastric ulcers do heal. Until healed, they should be regarded with suspicion. If meticulous attention is paid to the patient's subjective and objective symptoms and care taken to correlate them with expert roentgenologic examination, gastric secretory findings and, if necessary, gastroscopic examination, the decision can be made in most cases whether one is dealing with a benign or a malignant lesion. Fewer mistakes would be made in the diagnosis of these gastric lesions if physicians were less complacent in assuming that an ulcer is healing. On the other hand, when an ulcer is not healing, intractability should not be assumed until it has been determined, beyond reasonable doubt, that the patient has been following an appropriate ulcer regimen. In many cases, to say the least, adherence to treatment

has been compromised. I suspect that there are more refractory patients than there are intractable ulcers. They frequently masquerade, one for the other, and should be carefully considered in an appraisal of treatment. A truly intractable ulcer is one that is hopelessly chronic and sclerotic or one that has become adherent to adjacent structures. It is difficult to think of its responding favorably to any type of medical treatment. The refractory patient, on the other hand, frequently complicates the best kind of medical or surgical management. If one is unwise enough to operate on him, he is certain to cripple a good surgical record. Surgery will not cure him and medical management at best will but temporarily appease him. He frequently is the product of an undisciplined childhood and might best be benefited by some hopeful and ambitious psychiatrist.

A model plan of life for patients with ulcer such as has been referred to in principle not only would promote healing, but would minimize the risk of complications and recurrence in most cases. It should be undertaken, however, with the understanding by the physician as well as the patient that infraction means recurrence. I think that we do an injustice to our patients, as well as ourselves, if we allow them to assume that any manner of treatment, be it medical or surgical, will ever permit them to compromise with the ulcer plan of life. They can expect immunity no more than the tuberculous or diabetic patients can from nonobservance of the restrictions placed on them. I realize that this is not in harmony with the advice which many patients are given, that they can eat and do almost anything they please with impunity after their operation. I strongly suspect that such advice is responsible for many recurrences. In the light of our present knowledge, I believe that we should regard ulcer as an incurable disease, but still recognize that it may be held in abeyance by cultivating a new manner of living. With some, this is easy; with others, who are involved in a squirrel cage existence, it is difficult if not impossible. In occasional cases in which the ulcer is adherent to other structures or is so sclerotic that no medical measures can hope to hold promise of recovery, surgical intervention becomes necessary. Under these circumstances, it is advisable to perform as conservative an operation as possible, always with its limitations definitely in mind. Certainly gastroenterostomy, resection, a second resection, supra-diaphragmatic vagotomy, subdiaphragmatic vagotomy and an assorted combination of the lot indicate a lamentable lack of confidence in the surgical management of ulcer and do not augur well for the patient who is faced with an operation for his disease.

And so, in closing, I would express a word of caution. Medical methods for the treatment of ulcer undeniably have their limitations. However, in view of the disillusionments and disappointments attending surgery of the past that wrecked the physiologic mechanism of the digestive tract, let us beware of further innovations in surgery that are not based on sound physiologic principles and do not bode well for the patient. We may justly keep in mind that a poor result from an operation is a failure in the records of the surgeon, but a disaster in the life of the patient. *Aequanimitas!*

Rittenhouse-Plaza.

ABSTRACT OF DISCUSSION

DR. WALTER L. PALMER, Chicago: I have selected three statements from Dr. Boles' paper which build the thesis perfectly. "The crux of the ulcer problem . . . is the matter of cell resistance on the part of the gastric mucosa." Resistance to what? The next quotation is, ". . . cellular resistance depends on the state of the circulation in the stomach and on the chemical composition of the blood reaching the cell." That is part of the answer; the other part is that the resistance of the mucosa depends more on the protective layer of mucus.

Another quotation: "Bachrach, Grossman and Ivy have recently demonstrated that autodigestion of the stomach does not occur if the circulation to the mucosa is adequate and if the metabolic and nutritional condition of the patient is sufficient to maintain the tolerance of the cells to the acid-pepsin secretion and to provide for their regeneration and proliferation and for the secretion of mucus." The crux of the ulcer problem is how to protect the cells of the mucosa against the acid attack. The present trend is to relate this phenomenon to increased secretion of acid gastric juice and increased motility as a result of psychosomatic disturbances. The remarkable results of vagotomy, in which the emotional state of the patient is—shall I say—severed from the stomach by the surgical procedure, would seem to offer strong support for this hypothesis, but whether it is the whole explanation remains to be ascertained. Proceeding from this consideration to the treatment of peptic ulcer, at least 90 per cent of the patients with duodenal ulcer can be treated satisfactorily with the standard medical procedures. With regard to surgical procedures, resection in my judgment is indicated for those gastric ulcers considered carcinomatous or "intractable"; one must be careful if one undertakes to treat a gastric ulcer medically. In duodenal ulcer, operation is indicated primarily for obstruction. I prefer the combination of gastroenterostomy and vagotomy. Time will be required to determine whether jejunal ulcers form after this procedure with significant frequency. The dramatic results of bilateral vagotomy in the treatment of jejunal ulcer recurring after subtotal resection for duodenal ulcer suggest that the recurrence of ulcer after gastroenterostomy and vagotomy will be low.

DR. FRANK H. LAHEY, Boston: I should like to approach an ulcer problem in a patient as I would like it approached in me. I would want to be sure that you physicians had exhausted every possibility of nonsurgical measures. This would include a period of bed rest if for no other reason than to educate the patient in the method of treating himself. It would include impressing the patient with the need of an alteration in his way of life, something that I am sure he has neglected, particularly because the patient wants short cuts and does not know the penalty and price that he may pay for them. If these fail I should like to do a subtotal gastrectomy because it is a seasoned and proved procedure. The mortality in experienced hands is down to about 2 per cent or less, and this even in the cases of most intractable and adherent ulcer. I should like, if it is gastric ulcer, to operate on 100 per cent of them because it is, in my opinion, impossible without serial sections to know whether or not the lesion is malignant. Finally, I should like to reserve vagotomy for those patients who have been through this approach to the problem. If after a subtotal gastrectomy a gastrojejunal ulcer develops, I would then feel that the seriousness of another subtotal gastrectomy and the possibility of another recurrent ulcer would more than offset the unknown hazards of a vagotomy in this case. I do not want to employ this operative procedure with unknown consequences with any routine frequency at least until more evidence has collected. This debatable procedure may with time prove to have too many undesirable sequelae to make it valuable in anything more than in selected cases. There is one other condition in which we have applied vagotomy, and that is in those patients with duodenal ulcer who have bled repeatedly and on whom subtotal gastrectomies are to be done for bleeding. The incidence of recurrent bleeding has been so high in these cases that we have felt justified in adding infradiaphragmatic vagotomy to the subtotal gastrectomy in cases of peptic ulcer of this type. Our gastroenterologists do not agree with us whole-

heartedly regarding the question of submitting all patients with gastric ulcer to subtotal gastrectomy, but the reason I feel so strongly about it is that it is impossible to get patients who are under medical treatment back for observation often enough so that they do not occasionally return with inoperable carcinoma. The figures for cancer of the stomach are so bad and the mortality for subtotal gastrectomy for ulcer is so low that I feel that if I had a gastric ulcer I would accept the risk of subtotal gastrectomy with its almost absent mortality as opposed to the risk of malignant degeneration in the ulcer. Subtotal gastrectomy for duodenal ulcer, particularly in the type which is adherent to the head of the pancreas, and to the common duct, is a difficult and dangerous operation. Vagotomy is a simple and easy operation, but I plead against its promiscuous use by any one unable to do it well or to follow it accurately.

DR. A. F. R. ANDRESEN, Brooklyn: Dr. Boles has done a great service in presenting this review of ulcer therapy. I agree with practically everything that he said. He mentioned that at autopsy, multiple scars of ulcers have been found, attesting to the healing of ulcers. Any one who goes to the trouble of having repeated roentgenograms done on patients will see how rapidly an ulcer heals completely, most of the time without even evidence of scarring. We know from history taking that patients have self-limiting recurrent attacks of ulcer and that they have no symptoms between the attacks, and if we take roentgenograms between the attacks, we know that no ulcers are found. We know that practically all ulcers are accompanied by an increase in acidity. Is it possible that this sudden increase in secretion of acid may be a protective phenomenon, and that the acid helps to clean out the base of the ulcer and improve healing? Lewis Gregory Cole, years ago, demonstrated that the ulcer is the result not of lowered resistance of the mucosa to acid but of an actual necrosis of mucosa which is, of course, not protected from the acid secretion and is therefore digested out. Complications have been mentioned, and I think that the most frequent complication, the one that causes true intractability as shown by roentgenograms, is the so-called slow perforation, the perforation which is walled off by adhesions to the pancreas or to some other neighboring organ or which is covered up by omentum. Such a perforated ulcer will not heal by any medical methods, and will usually require operation. Unless conditions known to cause ulcer are eradicated, we cannot expect to prevent ulcers from recurring. We know that actual infection is not often the cause of ulcer, but the relation between ulcer and focal infection is becoming more and more evident. The formation of ulcer is probably due to some histamine-like substance absorbed from the focus which causes the end artery obliteration producing the ulcer. Thorough eradication of focal infections is the surest method of prevention of ulcers.

DR. SAMUEL FRIEDMAN, New York: In 1919, after observing a progressive increase of ulcers of the stomach and of coronary and cardiac disturbances in middle-aged persons, I concluded that the cause was long, hard hours of labor and travel, and became convinced that the work week should be reduced to five days. I urged this idea on the American Federation of Labor, our government and the people. In 1924 the American Federation of Labor adopted the five day week. If people would use to proper advantage these two rest days a week, in intellectual and physical recreation, I believe that many gastric ulcers and heart troubles would be obviated. When a man leaves his work in pain and goes away for a rest, he eats anything and feels all right. When he comes home and begins to worry about his bills and his business he again gets pains in the stomach or around the heart. I tell these persons, "Go away every week or every other week for two or three days. Forget your business troubles." By sensibly observing the weekly two day rest, I am sure we can limit the formation of ulcers and their recurrence and prevent a great many attacks of angina pectoris, coronary thrombosis and cardiac dilatations, if we but observe the five day week and the Tenth Commandment.

DR. ASHER WINKELSTEIN, New York: We agree with Dr. Boles in practically everything except his central thesis, namely, the unimportance of the "acid factor." Peptic ulcer is probably a psychosomatic disease in most cases. However, whatever

the ultimate cause of ulcer may be, it must be admitted that the immediate mechanism of its production in the stomach is the action of hyperchloric acid and pepsin on a susceptible mucosa. Ulcer adjacent to ectopic gastric secretory tissue in a Meckel diverticulum is striking evidence of the importance of the acid factor. Whatever dispute there may be about the etiologic significance of acid and pepsin, there should be little doubt about their central importance in the problem of ulcer therapy. The important older studies of Walter Palmer at the University of Chicago and recently of Professor Pickering of England have shown conclusively that the pain in ulcer is produced by crises of increased gastric acidity. The control of this acidity by the Sippy therapy in the daytime and by the drip therapy at night has stopped ulcer pain. The acidity at night, as we have repeatedly demonstrated, is high in duodenal ulcers. We have shown that the symptoms disappear and the ulcer heals best when this acidity at night is controlled by the intragastric drip therapy. Despite Dr. Boles' comment, I wish to state that we have treated several hundred patients with ulcer easily and successfully with my continuous intragastric drip therapy. Dragstedt has recently shown that the diminution of this secretion at night by vagotomy cures peptic ulcer rapidly and perhaps permanently in most cases. Our studies at the Mount Sinai Hospital have shown a night achlorhydria in 54 per cent of patients with duodenal ulcer who had gastroenterostomy combined with vagotomy, and in 94 per cent of patients with duodenal ulcer who had subtotal gastrectomy combined with vagotomy. This achlorhydria guarantees against a recurrence. Our earnest belief today is that the medical induction of continuous achlorhydria by the drip therapy, particularly during the night, and the surgical induction of an achlorhydria by the addition of vagotomy to gastroenterostomy or subtotal gastrectomy have gone far to solve the problem of the medical and surgical treatment of peptic ulcer. We subscribe to the dicta, "no acid, no ulcer"; "control of free acid, then rapid healing of ulcer"; "no postoperative free acidity, no recurrent ulcer." It does not seem advisable at the present time to relegate the acid-pepsin factor in ulcer to the realm of forgotten or fruitless theories.

DR. RUSSELL S. BOLES, Philadelphia: Dr. Palmer, I would not say that we had any serious disagreements concerning this subject. I want to reiterate, however, that I believe the matter of cell resistance comes ahead of the matter of acidity, and I subscribe to the belief that cell resistance depends on an adequate circulation to the mucosa of the stomach, as has been demonstrated, as Dr. Palmer quoted me in saying, by Ivy and his group as well as others. Dr. Palmer apparently got the impression that I did not use antacids. Of course I use antacids in the treatment of ulcer. I believe, however, that antispasmodics and sedatives are more important. I am not a therapeutic nihilist in any sense of the word in this matter of ulcer, and I believe antacids in the treatment of the acid, which is a contributing cause and an important one in ulcer, are very necessary. It never seems to happen that Dr. Lahey says anything with which we can disagree. I will, however, comment on his statement that all gastric ulcers should be resected. I believe that if meticulous attention is paid to the subjective and objective symptoms of these patients and those symptoms are correlated with skillful roentgenologic examination from time to time, and perhaps gastroscopic examination, we can determine whether an ulcer in the stomach is benign or malignant. This matter must be tempered with a lot of common sense. Are you going to feel that you should do a disabling operation, a resection, on 9 patients with benign ulcer who may some day have a gastric cancer—and the chances are that they will not—in order to save one who might slip through your fingers and develop a cancer. We may just as logically do a hysterectomy on every woman with a cervical erosion. Dr. Winkelstein, unfortunately, got the impression that I said that gastric acidity was unimportant. I did not say any such thing. I think, again, it is very important, but I do believe that it is a secondary matter and is apt to be the result rather than the cause of the ulcer and the pylorospasm associated with ulcer. I do not want to give the impression that I believe acid is unimportant. I think that the intragastric drip is effective in controlling acidity. As I said before, however, I think that we can accomplish the same end in other ways.

ORAL PROPHYLAXIS OF RHEUMATIC FEVER WITH PENICILLIN

Resistant Hemolytic Streptococci

ALBERT MILZER, Ph.D.

KATE H. KOHN, M.D.

and

HELEN MacLEAN, A.B.

Chicago

When military populations are undergoing mass chemoprophylaxis with moderate doses of sulfonamide drugs various workers have shown that group A hemolytic streptococci readily become resistant to the drugs. The dosage employed usually varied from 0.5 to 1 Gm. daily. Earlier reports¹ acclaimed these so-called prophylactic dosages of sulfonamide drugs as being effective in preventing outbreaks of infections with hemolytic streptococci as well as recurrences of rheumatic fever. Later it became evident that epidemics of hemolytic streptococcus infections occurred despite prophylaxis as a result of the development of resistant strains.² Increasing the daily prophylactic dose to as much as 2 Gm. failed to check the course of such epidemics.^{2b}

While it is known that hemolytic streptococci may readily acquire resistance to penicillin *in vitro*³ and *in vivo*,⁴ there have been no reports to our knowledge on the development of resistant hemolytic streptococci following oral prophylaxis with penicillin of either rheumatic fever or infections of the upper respiratory tract. In fact Lapin⁵ has recently recommended the use of small oral doses of penicillin (25,000 units daily) for prophylaxis of infections of the upper respiratory tract in children, but he reported no laboratory tests for the detection of penicillin fastness.

This paper is a preliminary report on the occurrence of penicillin-resistant strains of beta hemolytic streptococci in the throat culture of children with rheumatic fever who daily received 100,000 units of penicillin orally for at least five months to prevent recurrence of rheumatic fever. We feel that it is extremely important to report these observations on the development of penicillin fastness because of the present widespread usage of inadequate dosages of penicillin for prophylaxis or therapy in hemolytic streptococcus infections. Furthermore, the development of numerous resistant strains obviously reduces the value of penicillin therapy and may even give rise to epidemics that could not be controlled with penicillin. For example, sulfonamide-fast strains of gonococci are being encountered clinically with increasing frequency, so that the value of sulfonamide drugs in the treatment of gonorrhea is rapidly being nullified.

METHODS OF STUDY

Throat cultures were made of 114 children with rheumatic fever ranging in age from 7 to 11 years. All attended the same special school for children with rheumatic heart disease. Immediately after collection, swabs were placed in thioglycollate mediums and incubated six to eight hours at 37 C. Blood agar plates prepared from citrated human blood were then streaked and incubated aerobically at 37 C. for eighteen to twenty-four hours. Predominant organisms in the throat culture were noted and representative alpha hemolytic, beta hemolytic and gamma or indifferent streptococcus colonies were picked and grown in pure culture for tests of sensitivity to penicillin.

A turbidity test was used to determine the sensitivity of the streptococci isolated. Two sets of serial twofold dilutions of penicillin in ascitic dextrose broth ranging from 5 to 0.0025 Oxford units per cubic centimeter were prepared. Organisms resistant to 5 units were retested with 10 units. The test organism was grown in ascitic dextrose broth for six to eighteen hours at 37 C. or until the turbidity of the culture was equivalent to a concentration of approximately 600,000,000 organisms per cubic centimeter. One tenth cubic centimeter of a 1/1,000 dilution of the test organism was then added to each dilution tube and to a control tube not containing penicillin. Simultaneously, a similar amount of a six hour culture of *Staphylococcus aureus* (strain 209-P) was added to the second set for comparison and to check the potency of the stock penicillin solution used. Both sets were incubated for eighteen hours at 37 C., and the least amount of penicillin (units per cubic centimeter) needed to inhibit growth was recorded.

RESULTS

Sixty-four of the 114 children with rheumatic fever were given an oral dose of 50,000 units of penicillin⁶ twice daily on a fasting stomach from December 1946 to June 1947. The remaining 50 children received no penicillin but were in constant daily contact at school with those receiving penicillin. Throat cultures were made from April to June 1947 so that the test group had received penicillin daily for at least four months prior to culturing. No reactions to penicillin were noted.

Table 1 shows the incidence of the various types of streptococci in throat cultures of the treated and untreated groups. In both groups the type of streptococcus isolated varied from approximately 10 to 100 per cent of the throat culture. In most instances when beta hemolytic streptococci were isolated they represented approximately 50 to 100 per cent of the specimen studied. The incidence of beta hemolytic streptococci

6. Oral penicillin tablets (crystalline penicillin G potassium) provided by the Commercial Solvent Corporation were used.

in both groups closely approximates the normal carrier rate in healthy children as reported in the literature.⁷

Results obtained in tests of sensitivity to penicillin of strains of alpha and beta hemolytic streptococci isolated from the treated and untreated groups of children are summarized in table 2. Strains of beta hemolytic streptococci resistant to 10 or more units of penicillin per cubic centimeter were considered significantly resistant, while the sensitivity of the remainder of the strains which were considered nonresistant ranged from 0.02 to 0.625 unit. The latter figure for nonresistance was chosen because in routine penicillin sensitivity tests of hemolytic streptococci isolated from various infections and healthy carriers not previously treated with penicillin no strains have been encountered which were resistant to more than 0.625 unit. In fact the range of sensitivity of most strains isolated was 0.02 to 0.04 unit. Similarly, the range of sensitivity of strains of alpha hemolytic streptococci which were designated nonresistant was 0.04 to 1.25 units, with most strains sensitive to 0.15 to 0.31 unit. These sensitivity figures are in general agreement with those stated in the literature.⁸ The range of sensitivity of gamma (indifferent) streptococci isolated in this series was 0.04 to 1.25 units. No sensitivity figures on gamma streptococci from untreated individuals are available for comparison.

COMMENT

Although no studies were made on the sensitivity of strains of beta hemolytic streptococci prior to giving penicillin, the finding of 82 per cent resistant to 10 or more units in the group receiving penicillin is significant. As has been mentioned, no strains have been encountered resistant to more than 0.625 unit in routine tests of sensitivity to penicillin prior to drug therapy. It is unfortunate that we were unable to type the strains of beta hemolytic streptococci isolated, but Lancefield typing serums were not available at the time of this study. According to Meads and others^{8a} and Rantz and others,^{8b} group A hemolytic streptococci do not possess any natural resistance to penicillin. On the basis of reports in the literature on the distribution of group A hemolytic streptococci in the throats of normal children⁷ it can be assumed that at least half of the resistant strains isolated in this series belong to group A. The fact that 40 per cent of beta hemolytic streptococci from the group which did not receive penicillin were significantly resistant is probably best explained by the frequent opportunity for cross infection between the two groups since, as has been stated, they were in constant contact for at least four months prior to culturing.

The observation that only about 10 per cent of alpha hemolytic streptococci were resistant to 10 or more units of penicillin in both the test and control groups of children is probably not significant. Greater variability of strains in sensitivity to penicillin and even the occurrence of naturally resistant strains have been reported for this group of streptococci.^{8a, c} Our results

thus far indicate that those alpha hemolytic streptococci which do acquire significant resistance to penicillin, do so more slowly than the beta hemolytic streptococci.

Because our results show the development of significant resistance of beta hemolytic streptococci to penicillin, additional experiments are being planned in which larger oral doses of penicillin will be given daily for prophylaxis against recurrence of rheumatic fever. Throat cultures will be made just before and one month after the administration of penicillin to determine initial sensitivity of the streptococci and the possible development of resistance to the drug. Two recent reports⁹ indicate that 500,000 to 1,000,000 units of oral penicillin daily for six days should be ample in most instances to rid the throat of hemolytic streptococci and thereby avoid the possibility of penicillin fastness. There can be no objections to using these large dosages of penicillin for prophylaxis because of toxicity, as is the case with the sulfonamide drugs.

SUMMARY

Throat cultures for alpha and beta hemolytic streptococci were made for 114 children with rheumatic fever. Sixty-four of the children were given a prophylactic

TABLE 2.—Resistance of Streptococci Isolated from Throat. Cultures of Children Having Rheumatic Fever With and Without Penicillin Prophylaxis

oral dose of 100,000 units of penicillin daily for at least four months prior to culturing in order to prevent recurrences of rheumatic fever. The incidence of beta hemolytic streptococci in both groups closely approximated the normal carrier rate in healthy children as reported in the literature.

Eighty-two per cent of the penicillin-treated and 40 per cent of the untreated groups of children had beta hemolytic streptococci of significant resistance to penicillin present in their throats. The occurrence of resistant strains in the untreated group can probably be explained by cross infection; since the two groups were in constant contact.

Inconclusive results were obtained on the development of significant penicillin resistance by alpha hemolytic streptococci isolated. There was some indication that resistance develops somewhat more slowly than in beta hemolytic streptococci.

It is suggested that larger oral doses of penicillin be used for prophylaxis than is recommended in the literature in order to prevent the development of penicillin-resistant strains.

ADDENDUM

Since this paper was submitted for publication we have found that 1,000,000 units of oral penicillin given daily for five days is usually ample to rid the throat of hemolytic streptococci and thereby avoid the possibility of penicillin resistance. Moreover, sixteen strains of nonresistant hemolytic streptococci were isolated from throat cultures of 46 children with rheumatic fever and 47 normal children not receiving penicillin. Eight strains of streptococci were isolated from each of the two groups of children.

SURGICAL TREATMENT OF INTRACTABLE UNILATERAL CEPHALALGIA

WALTER G. HAYNES, M.D.
Birmingham, Ala.

The conquest of headache can be accomplished only by separation into various clinical entities and the application to each entity of specific drugs or surgical therapy. The vascular element contributing to the propagation of migraine has been frequently demonstrated. Harris¹ in 1936 pointed out the association of vasomotor changes in the cerebral vessels as demonstrated by scotomas, transient paresis, mental depression and visual field disturbances. Clark, Hough and Wolff² found that headache was due to excessive pulsation and stretching of the walls of the dural and temporal arteries. Penfield,³ Harris and Penfield and McNaughton⁴ caused relief from a migrainous headache by selective section of the upper fibers of the trigeminal root which interrupted the sensory fibers to the dura and scalp traveling beside the blood vessels. However, in Penfield's operation to expose the trigeminal root, he must have severed the middle meningeal and temporal arteries as well. Severe hemicrania has been relieved by cervicothoracic sympathectomy, notably by Love and Adson,⁵ Dandy⁶ and Craig.⁷ However, the follow-up on this procedure is difficult, and it seems that nowhere can consistent results be obtained by this method of approach.⁸

It is well known that the dura, in large part, is insensitive but that fibers from the second and third divisions of the trigeminal nerve course beside the middle meningeal artery. The first division of the trigeminal nerve sends fibers to the midline dural structures. There has never been adequate demonstration, however, of transmission of sensory fibers over the superior portion of the cervical sympathetic trunk. Cervicothoracic ganglionectomy or procaine block has

not reduced the pain on the denervated side, according to White and Smithwick.⁸ Further, Solomon⁹ has not demonstrated a general sympathetic disturbance during the progression of a migraine headache by the measurement of resistance of the skin or following the relief of the headache by ergotamine.

In other words, migraine per se, while apparently a vascular type of headache, still has a shadowy pathogenesis. All the available evidence suggests that the autonomic nervous system is implicated in the abnormal pulsations of the external carotid artery, important in vascular headaches, but the exact pathway of these impulses is questionable. Probably one of the more important contributions in this respect is that of Kuntz,¹⁰ who in 1934 gave a priori evidence that there are sympathetic afferent fibers along the course of the middle meningeal arteries and the superficial temporal arteries by establishing their presence in the adventitia of the external carotid artery. He proved that there were nerve fibers of spinal and vagus origin associated with the cephalic sympathetic nerves as well as with the external carotid artery.

Because of this primary interest in the vascular aspects of migrainous headaches, it was noted with interest that a vascular type of headache, apparently mediated along the temporal artery, caused a paroxysmal unilateral type of pain with radiation into the ipsilateral eye, associated sometimes with reddening of the conjunctiva and occasionally tearing. The temporal artery is tender at the time of the headache and an injection of procaine about the artery will give relief of this pain. Eight such isolated cases have previously been reported by Nadler¹¹ and commented on by Newman.¹²

With this original concept, a search has been made for corresponding headaches. At the present time a series of 72 cases of unilateral intractable cephalalgia has been compiled, in 47 of which surgical treatment has been given. An attempt has been made to keep the pure migraine headache from this series. Twenty-five such headaches have been treated conservatively, and tables showing the relative value of each method of treatment and relative percentage of relief to be expected from each have been prepared (tables 1 and 2). It is evident that conservative treatment affords some 32 per cent of relief and surgical treatment 87 per cent of relief.

It seems best to subdivide the types of unilateral cephalalgia into the following components: 1. Temporal vascular headache, a migraine-like entity, apparently due to afferent sympathetic pain pathways accompanying the external carotid artery and its branches, causing severe unilateral temporo-orbital pain, reddening of the conjunctiva, tearing of the eye and tenderness of the temporal artery, relieved temporarily by injection of procaine about the artery. This syndrome exhibits no shimmering scotomas or gastrointestinal symptoms. It is relieved by section of the temporal artery, although occasionally, if the pain seems more deep seated or severe, the middle meningeal artery is also ligated and divided, a logical procedure when one considers the

common source of the two branches. 1 (a). Occipito-temporal vascular headache with radiation of pain extending up over the occipital nerve, along the course of the temporal artery and into or about the ipsilateral eye. This entity may not exhibit the conjunctival reaction or the tearing, but the occipital nerve and the temporal artery are tender to palpation. It is believed due to spinal sympathetic afferents through the greater occipital nerve. Procaine infiltration about the occipital nerve gives temporary relief, and section of the occipital nerve and artery with section of the temporal and middle meningeal arteries gives permanent relief. 2. Cervical radiculitis due to involvement of the occipital nerves by cervical arthritis, peri-arthritis or fibrositis, or even malformation of bone. This pain may be made worse on motion of the neck, and it may be relieved by traction of the neck. A small percentage of patients with this cervical radiculitis reveal by roentgenogram a cervical arthritis. It is possible that a protruded cervical disk might simulate this syndrome. This symptom complex seems to be one of pure mechanical pressure, and the

Apparent sympathetic afferent pathways.

pain is not referred to the temporal region. The pain apparently caused by cervical arthritis or peri-arthritis may be relieved by application of high voltage roentgen therapy to the cervical portion of the spine. A greater number, however, can be relieved by avulsion of the greater occipital nerves. 3. True intractable migraine, consistent as to lateralization, thought to be a vascular headache, mediated along the same pathways but with the added component of vascular imbalance of cerebral vessels.

Examination of the accompanying figure will reveal the autonomic fibers thought to be incriminated in this type of headache. It is true that afferent sympathetic fibers accompanying the branches of the external carotid have not been identified, but it is felt that the work of Kuntz has established their existence. Although there is no direct proof, it is believed that the spinal sympathetic afferents to the greater occipital nerve are incriminated. That this type of pain is not mediated along the occipital artery accompanying the greater occipital nerve has been demonstrated by selective avulsion of the nerve leaving the artery intact with consequent relief of pain.

Three patients have complained of unilateral headache with the usual accompanying symptoms, and have

traced the course of the external carotid artery as they delineated their pain. Carotid pressure relieved the headache and section of the temporal and meningeal arteries has relieved the pain. The external carotid was not divided in the neck because it is not known how many fibers enter its adventitia as it passes through the neck next to the sympathetic chain.

While it is not believed that afferent fibers course along the occipital artery, as they apparently do along the temporal or meningeal arteries, it must be noted that the occipital artery is the first branch of the external carotid artery and that it is a possible pathway.

Gardner, Stowell and Dutlinger¹³ have described the surgical relief of a unilateral headache by division of the greater superficial petrosal nerve. This follows the line laid down by Foley,¹⁴ Bruesch¹⁵ and Hinsey,¹⁶ as they described the coursing of somatic afferent fibers from the seventh, ninth and tenth nerves along the adventitia of blood vessels. It is not believed these fibers are involved in the type of vascular headaches described here, although in Gardner's type of headache they may be the main factor. It is believed the pathways herein involved are afferent sympathetic fibers rather than somatic afferent (seventh, ninth and tenth nerves) or parasympathetic (seventh), as Gardner's must be.

On this basis the surgical technic has been developed. It consists of exposure of the temporal artery with the patient under local anesthesia with excision of a portion of the temporal artery between silver clips in an attempt to prevent regeneration of any fibers. The

allow this artery to be divided and a portion excised between silver clips. The dura is opened between these clips to insure division of any fibers which may have been missed in the excision of the artery. The wound is closed in the usual fashion with interrupted black silk sutures. The hospitalization necessary is usually three days. The occipital nerve may be avulsed with the patient under local anesthesia by a curvilinear incision just lateral to the posterior occipital protuberance. Here the occipital artery, vein and nerve are easily identified. The nerve is rolled up on a hemostat and avulsed for a distance of 3 to 5 cm. The wound again is closed in the usual fashion with interrupted black silk sutures. Neither of these procedures is hazardous, and in trained hands they do not constitute any danger to the patient's life or allow any untoward sequelae. There have not been any fatalities in this series.

Cross section case reports are herein presented in an attempt to demonstrate various points thought to be of importance.

REPORTS OF CASES

CASE 1.—Attention was attracted to the problem by interest in this young soldier, aged 21, who experienced classic symptoms of paroxysmal type of unilateral pain in the right temporal region which radiated into the right eye. It was accompanied by reddening of the conjunctiva and tearing of the right eye. The temporal artery was tender. Injection of procaine about the artery caused a cessation of the incapacitating headache. The temporal artery was ligated and divided and the pain was immediately relieved. The relief has persisted now for six years.

CASE 5.—This soldier, aged 22, was seen in an evacuation hospital in Belgium. He had wounds of the extremities which were not serious, but he was complaining bitterly of pain in his right temple, with projection of the pain into the right eye, accompanied by reddening of the eye and tearing. On examination of the scalp it could be seen that there was a tiny puncture hole just about the zygoma on the right side. A diagnosis was then made, without the benefit of roentgenograms, of a metallic foreign body lying on the temporal artery and causing the typical temporal sympathetic pain by stimulation of the sympathetic afferent fibers. A roentgenogram was taken and the metallic foreign body visualized. A small incision was made over the temporal artery and the foreign body was seen to be lying exactly on the temporal artery, although it had not severed it. The foreign body was removed and the pain disappeared. The temporal artery was not divided or ligated. The patient remained free of pain for the period of follow-up, approximately six months.

CASE 21.—A woman aged 37 complained of severe, intermittent, paroxysmal, unilateral headaches on the left side for the previous four years. They had become progressively worse, and at the time of her first visit they were occurring twice a week and were incapacitating. They were not accompanied by scotomas, visual disturbances or nausea. They were not preceded by an aura. The pain radiated about the left eye. The conjunctiva was not reddened, but occasionally there was some tearing during the height of a headache. The temporal artery was tender on palpation. She had been treated with ergotamine tartrate, histamine and nicotinamide. The only relief to be obtained came from morphine or dihydromorphine hydrochloride. A diagnosis of temporal vascular headache was made and the temporal artery and the middle meningeal artery divided and portions excised with the patient under local anesthesia. The relief of the pain was immediate and has persisted for twelve months, with the exception of an occasional generalized, mild headache, relieved by acetylsalicylic acid.

CASE 32.—This patient, a man aged 27, had had severe, intractable, unilateral headache for the previous eighteen months. It began at the base of the skull on the left side and radiated up over the ear along the course of the temporal artery and

occasionally about the left eye. The pain was severe and incapacitating and occurred two to three times a week. It was paroxysmal. On examination, the temporal artery and the occipital nerve on the left side were tender to palpation. No pathologic condition in the cervical part of the spine was observed by roentgen examination, and it was not tender to palpation. Accordingly, the temporal artery and the middle meningeal artery on that side were ligated and portions were resected. The occipital nerve was exposed and avulsed for a distance of 4 cm. The patient had an immediate relief of his headache, and has remained free from pain for the past twelve months.

CASE 36.—This white woman, aged 42, complained of pain beginning in the upper cervical portion of the spine, radiating up over the occiput along the course of the right temporal artery and just above the right eye. The temporal artery was tender to palpation, the occipital nerve was tender and motion of the neck caused the pain to be worse. There was tenderness between the spinous processes of the second and third cervical vertebrae. The pain was incapacitating and was almost continuous, although she felt that it became worse at times. Roentgenograms of the cervical portion of the spine revealed minimal arthritis of the entire cervical part of the spine involving the facets.

The temporal artery and middle meningeal artery were ligated and portions were resected. The greater occipital nerve was avulsed for a distance of 5 centimeters. Relief of the pain was immediate and persisted for the past eleven months. The cervical part of the spine, however, has remained somewhat painful to motion, and the tenderness between the second and third vertebrae has persisted. This pain, however, is not incapacitating or severe. The headache has been relieved. She had previously had treatment by means of roentgen therapy directed to this region and traction on the neck.

CASE 41.—This woman, aged 35, had been suffering from typical migraine headache confined to the right side, precipitated by an aura of blurring of vision. The severe unilateral headache was accompanied by shimmering scotomas and nausea. There was a family history of migraine. It occurred once or twice a week, necessitating confinement to bed.

She had had treatment with histamine desensitization, ergotamine tartrate and nicotinamide, and a search had been made for some offending protein by the allergists, all to no avail. She felt that she was incapacitated. The pain seemed confined to the right temporal region and there was no indication of any involvement of the greater occipital nerve. Accordingly, the temporal artery and the middle meningeal artery were resected in the usual fashion. The headaches were relieved. At the period of three months, she began to have an occasional mild type of hemicrania which could be relieved by the use of acetylsalicylic acid. This headache would last only two to three hours. It was accompanied by scotomas and by nausea. The great component of a severe and incapacitating headache, however, was missing.

CASE 46.—This man, aged 29, had the usual typical paroxysmal type of unilateral pain, accompanied by tenderness of the temporal artery and reddening of the conjunctiva and tearing of the eye. The occipital nerve was tender and the temporal artery was tender. The pain was incapacitating, occurring two to three times a week, necessitating confinement to bed. He had been treated with ergotamine tartrate, roentgen therapy to the cervical part of the spine, nicotinamide and desensitization with histamine.

It was felt that he fell into the category of sympathetic headaches, and accordingly his greater occipital nerve, the temporal artery and the middle meningeal artery were all resected. He had a good result which lasted for four months. The pain began to recur, although to a milder degree. He was then placed on nicotinamide, and while it had been a complete failure prior to operation, it afforded complete and lasting relief after the operation. This experience has been noted since, and it is found that the occasional mild headache which might recur after surgical treatment may be relieved by the use of nicotinamide.

COMMENT

Reference is made to the accompanying chart. It has been found in this series of 47 surgical cases that 87 per cent of these patients obtain a pronounced degree of relief from their severe, intractable, incapacitating unilateral cephalalgia. Conservative treatment affords 32 per cent relief. While surgical treatment may be applied to migraine in some cases, an attempt has been made to keep the true migraine from this series. An analysis has been made of the nervous pathways. Surgical technic has been described and the results thereof with a follow-up period have been presented.

SUMMARY

An attempt has been made to classify intractable, unilateral cephalalgia into three entities: (1) temporal vascular headache due to afferent sympathetic pain fibers accompanying the external carotid artery and its branches, associated with severe, unilateral pain, reddening of the conjunctiva, tearing of the eye and tender temporal artery; (1 a) occipitotemporal vascular headache with radiation of the pain up over the occipital nerve, along the course of the temporal and middle meningeal arteries; (2) cervical radiculitis due to mechanical pressure on the greater occipital nerve, and (3) true intractable migraine.

CONCLUSIONS

If a unilateral cephalalgia is truly intractable to conservative measures, then it seems logical by means of an innocuous surgical procedure to relieve the pain by means of rational treatment along physiologic lines.

Study of the pathways involved and the relief of the pain following surgical intervention directed at these pathways causes me to feel that there are sympathetic afferent fibers traversing the branches of the external carotid artery, namely, the temporal artery and the middle meningeal artery and possibly the occipital artery, and that these fibers are incriminated in the propagation of the vascular headache described.

Eighty-seven per cent of the patients given this diagnosis and surgically treated have been given lasting relief.

ABSTRACT OF DISCUSSION

DR. ROLAND P. MACKAY, Chicago: We are grateful to Dr. Haynes for drawing attention again to the surgical treatment of unilateral headache, a subject which has been discussed frequently, but perhaps too often forgotten. The essence of his problem is diagnosis. We know that the vast aggregation of headaches are difficult to separate one from another. Actually, the diagnosis of migraine itself is nearly always a matter of opinion. I am not so sure—not to be critical—that Dr. Haynes can always tell when he has a case of unilateral cephalalgia as distinguished from migraine. One has to remember, too, the facial pains of nondescript types which puzzle one. Some of these, I believe, are due to organic diseases which involve the various branches of the fifth cranial nerve; for example, syphilis, tumors and other pathologic conditions. We must not forget the great number of pains in the face and in the head which are of emotional origin, the so-called tension headaches or tension pains. These are usually not difficult to diagnose. May I ask Dr. Haynes whether it is necessary for him to sever the artery rather than to strip the wall of the artery and so sever the accompanying nerves? In other words, why not do a Leriche periarterial sympathectomy? May one not spare the artery in such an operation? We must realize that surgical treatment of pain in the head of this type is actually only symptomatic treatment. We must try, of course,

to discover and treat the cause in each case. With all of these qualifications and doubts, perhaps there still will remain a large number of patients for whom Dr. Haynes' approach will be of great value.

DR. PAUL BUCY, Chicago: Dr. Mackay has pointed out the diagnostic difficulties which the problem presents. The difficulties of treatment are equal to those of diagnosis. This type of attack is not new, and one which a number of persons have used in headaches of this type, as well as in migraine, in which many of us believe that the pain is of vascular origin. Recently Dr. Watts of Washington attempted section of the temporal artery with headaches of this type. Dr. Wolf of New York has attempted it, unfortunately, with failure. The latter has been the experience of most of us. That perhaps is not surprising, in view of the fact that the vascular phenomena associated with this pain, and probably responsible for it in a considerable measure, are not limited to the distribution of one artery, although they may be limited to the vascular supply of one side of the head or face. Therefore, a division of the temporal artery is likely not to give relief in many instances.

Certainly in instances in which pain can be relieved completely by the injection of procaine into the region of the temporal artery, the attack which has been advocated by Dr. Haynes is well worth trying.

DR. WALTER G. HAYNES, Birmingham, Ala.: In answer to Dr. Mackay's first queries, I try to limit the surgical treatment to those patients whose cephalalgia is truly intractable and to those who have been given a thorough and rather lengthy course of conservative medical treatment. It would be technically rather difficult to attempt a Leriche type of periarterial stripping of the temporal artery and the middle meningeal artery. Both are small arteries. Their function is of little prime importance, and their sacrifice means very little. As to the diagnosis, I am fully cognizant of the fact that I may have included other types of headaches in this series. I attempted not to, however. Two patients with true migraine did creep into the series. That diagnosis became obvious after the operation had been done. Most of these patients had been referred to me by psychiatrists who had followed them for some time. They had been convinced, as was I, that these were not a tension type of headache; that is, that they were not a neuropsychiatric problem. I will try to answer Dr. Bucy's question by saying that I have attempted to limit the surgical treatment to those patients in whom the three available arteries seem to be clinically involved and to whom injection by procaine about at least the temporal and occipital artery gave some relief.

Blood Transfusion.—The giving of Rh-positive blood to a Rh-negative recipient with preformed Rh antibodies in the plasma will result in the haemolysis of the transfused corpuscles. If the Rh-positive corpuscles are broken down rapidly, a dangerous, and sometimes a fatal, reaction occurs. If they are haemolysed more slowly, the patient may escape a severe reaction, but will fail to derive the maximum benefit from the transfusion. Moreover, the Rh antibodies will be considerably increased in potency, so that unless due precautions are taken, a subsequent transfusion may prove fatal. Such recipients will tolerate only blood that does not contain the offending Rh antigen, i. e. Rh-negative blood. . . . In 10 per cent of all pregnancies the foetus is Rh-positive and its mother Rh-negative. In certain instances the Rh-negative mother will react to the presence of the Rh-positive foetus as if she had received a transfusion of Rh-positive blood, and Rh antibodies will appear in her plasma. The placental barrier is freely permeable to these antibodies, which pass over into the foetal circulation and there react with the Rh factor in the baby's corpuscles and tissue cells. As a result of the interaction of Rh antigen and antibody in utero the baby suffers from a condition now known as haemolytic disease of the newborn (erythroblastosis foetalis). Haemolytic disease of the newborn complicates one in every two hundred to two hundred and fifty pregnancies, and is responsible for more deaths than any other inherited condition, perhaps more than all other inherited conditions together (Haldane, 1943).—Tovey, Geoffrey H., M.D.: The Rhesus Factors-I, *The Bristol Medico Chirurgical Journal* 54:68-73, Autumn 1947.

NUTRITION AND ENDOCRINOLOGY

With Special Reference to the Nutrition of the Mexican Indian

FRANCISCO DE P. MIRANDA, M. D.
Director National Institute of Nutrition
México, D. F., México

For the general practitioner, it is difficult to follow the lines of development of medical ideas in the different fields of medicine unless extreme care is taken in the presentation of facts and of doctrine. One must always bear in mind that the division of subjects in different branches of medical knowledge and their classification is done only for convenience, and does not exist in nature. Such is the conception of separation between nutrition and endocrinology and the classification of nutritional disorders into "exogenous" and "endogenous"; by "exogenous" those cases are meant which are caused by the ingestion of an excessive or an insufficient amount of food and by "endogenous" those derived from an endocrine disturbance.

It is true that one may find some cases which can be really recognized as exogenous and, in the other extreme, cases which can be recognized as endogenous, but such clearcut classification breaks down if it is recognized that the quantity and quality of food affect the function of the endocrine glands, so that exogenous disturbances sooner or later become mixed with endogenous disturbances.

The influence of food on the endocrine glands is gradually becoming known. It is not a new notion and the subject is so extensive that I cannot undertake to review it.

The first mention of an endocrine gland was made by Claude Bernard, the great French physiologist, who established that the liver was capable of pouring dextrose into the circulation in accordance with the need of the organism and that this substance was derived from glycogen stored in the liver cell.

More recently it was shown that lack of iodine in food led to a functional and even an anatomic disturbance of the thyroid gland.

"EXOGENOUS" AND "ENDOGENOUS" DISORDERS

For a long time evidence has been sought in favor of an "exogenous" origin of many cases of diabetes, which usually are preceded by obesity and in which the role of the pancreatic gland and even the pituitary gland cannot be denied.¹

Many cases which clinically resemble Froehlich's syndrome have been shown to be of exogenous origin and can be cured or at least favorably modified by diet without the use of therapeutic hormonal preparations.

Many cases of anorexia nervosa have been described as clinically indistinguishable from "true" hyperpituitary cachexia or Simmond's disease.²

So startling have been some of these observations that some have been carried to the extreme of saying that true endogenous obesity is rare and that there is no form of obesity that cannot be modified by diet.

The influence of food on the glands of internal secretion is not strange. All organs in the body are affected by food, and there may be grounds for believing

that the endocrine glands may be specially sensitive to variations in food consumption.

On the other hand, there is the possibility that a lack of certain nutrients may produce an effect which may be similar to a dysfunction of a certain gland. An example of this can be given in the clinical resemblance of cortical insufficiency to the picture produced by dehydration of exogenous origin.

If one accepts this point of view, there may be a parallelism between clinical pictures differing in etiological significance.

CLASSIFICATION OF DISTURBANCES DUE TO INSUFFICIENT NOURISHMENT

There are difficulties which arise from difference in nomenclature, which sometimes results from a tendency either to oversimplification or to excessive analytic diversification.

In this respect, I find it difficult for the American school to understand the European nomenclature and vice versa, as here in America oversimplification has led to the grouping of disturbances of insufficient nourishment in only two concepts: undernutrition and malnutrition, while in Europe there are terms like "athrepsia," "atrophy," "decomposition," "dysergias" and "dysontias," from the old French school of Parrot,³ from Finkelstein and from Bessau,⁴ which are not understood in America.

There are to my mind many reasons for reclassifying these disorders, and I hope that you will not find it presumptuous on my part to present this attempt of classification.

The disturbances caused by insufficiency of nourishment may be classed as (1) undernutrition, (2) malnutrition and (3) hypoproteinoses. You are familiar with the first two. The term undernutrition must be restricted to a deficiency in calories which produces loss of weight and reduction of fat deposits. This condition is usually seen in times of war or disasters which disrupt the distribution of food in the world. Malnutrition means a vitamin deficiency. I need not mention the different forms that it can assume in accordance with the particular vitamin involved.

Hypoproteinoses means a deficiency of protein food or of good quality proteins, or a deficiency of essential amino acids. It is the most common disease in the world, and yet it has not even a name in the accepted medical nomenclature.

HYPOPROTEINOSIS

The outstanding cause of hypoproteinoses is the low economic level on which half of the population of the world lives. This economic want leads to the suppression from the diet of the most expensive foods of animal origin, usually badly compensated by an excess of carbohydrates derived from the cheapest cereals or tubers: rice, corn and cassava.

It is usually a chronic condition difficult to overcome and is essentially different from the plight of the people under the stress of war or famine, which is usually acute and may be remedied by emergency measures, chiefly by cereals.

It is true that undernutrition, malnutrition and hypoproteinoses may be found superimposed, as now happens in China and India, because to the chronic lack of good quality proteins there is added a lack of certain vitamins, and also an insufficiency of carbohydrates and fats.

Address of the invited foreign guest read before the Section on General Practice of Medicine at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

4. Bessau, G.: *Ernährungsstörung*, Monatschr. f. Kinderh. 63: 4, 1935.

The extreme condition of lack of all kinds of food leads to inanition, which is usually spoken of as hunger.

But it is conceivable that the most frequent of all these conditions of want is that produced by insufficient protein or essential amino acids.

It happens, though, that one frequently refers to hypoproteinemia and not to the hypoproteinosis, although hypoproteinemia, connected with edema, is not a disease in itself but a sign of the general condition of hypoproteinosis, and an inconstant sign, as I will explain later.

This condition of hypoproteinosis in its dry form has been ignored because what is known about it has not been gathered in a coherent description but lies scattered in different chapters, and because physicians have ignored old descriptions of this disease just because they are not up to date in their information.

It is, moreover, a fact that hypoproteinosis in its dry form is difficult to recognize in an individual though easy to recognize as a disease of the community, as a public health problem.

If one analyzes the data found in vital statistics of countries or regions where hypoproteinosis exists one finds (1) a high general mortality, (2) a high infant mortality, (3) a high mortality for infectious diseases of childhood, (4) a high incidence of gastrointestinal disorders, (5) a high natality index and (6) low figures of height and weight of the population.

A glance at these general facts leads one to certain corollaries: 1. Hypoproteinosis is a condition which specially affects children before 6 years of age. 2. It affects them by (a) a tendency to stop or delay growth, (b) a tendency to diarrhea and (c) a low resistance to infection.

Growth is considered by nutrition workers one of the best criteria for the assessment of the protein value of foods. The growth of young rats is perhaps the best method of biologic appraisal of protein values.

But it happens that it is difficult to distinguish between racial and acquired characteristics. It is easy to create a good strain of rats with known biometric constants, but men differ widely from one another and it is easier to believe in race superiorities and inferiorities than to believe in the effect of food on racial development. And yet Scandinavians of today are 10 cm. higher in stature than their ascendants of one hundred years ago.

Height is a better index of protein nutrition than weight, which is rather an index of caloric deficiency.

Some years ago I pointed out to my students and also to my colleagues in the Academy of Medicine in Mexico that delay in growth caused by protein deficiency was similar to that caused by pituitary deficiency. This has been stressed by the observations of Dr. Rigoberto Aguilar.⁵

The studies of Cannon⁶ have led to the knowledge that growth retardation may be caused by deficiency of any of the essential amino acids.

Growth is essentially a sign of positive nitrogen balance, and the nutritional added requirement of food for growth purposes must be specially those of protein food.

The resemblance of the clinical picture of pituitary nanism to that of hypoproteinotic nanism is a fact which

may be interpreted in several ways: One could accept that for normal growth two essential conditions are necessary, proper nutrition and the function of the anterior pituitary. If either one of these conditions is lacking, the effect is the same.

But one could also consider the possibility that protein deficiency affects the pituitary gland. Most of the pituitary hormones are of a protein nature, and one can conceive that these proteins cannot be synthesized without a proper protein nutrition.

Low resistance to infection is manifested: (1) by the frequency of infections in hypoproteinotic children; (2) by the special severity of these diseases, so as to be a cause of high mortality even in usually benign infections such as measles and whooping cough, and (3) by a special course of the infectious disease itself, as for example, the absence in severe infections of fever and other body reactions such as leukocytosis and other immunity responses.

Kolmer⁷ stated that "the proteins of the diet are apparently just as important in the synthesis of natural specific antibodies (and presumably of the nonspecific bactericidal beta lysins, leukins and plakins of the blood) as they are in the synthesis of acquired antibodies, whereas A, C, D avitaminosis may favor infection through changes in the epithelial barriers, body secretions or other nonspecific factors."

He went on to say that "unless the nutrition of pregnant women is favorable to antibody production, the immunity of newborn infants, so likely to be classified as natural immunity, though actually a type of acquired immunity, will be deficient."

The findings of Heidelberger and collaborators⁸ identifying antibodies as molecules of globulin which in the course of their synthesis have been specifically modified by the antigen and the conception of Sabin,⁹ who defined antigens "as substances which can specifically modify the synthesis of globulins by the cells of the reticuloendothelial system" led to the theory postulated by Cannon¹⁰: "gamma globulin production is dependent on the intake of amino acids from proteins."

More recently experimental studies by Dougherty and White¹¹ and others have called attention to the lymphocyte as the special cell in which gamma globulins are synthesized and to the fact that, aside from the intracellular production of antibodies, there is another necessary step, the release of these antibodies by the dissolution of the lymphocytes, which is produced by the action of the steroids of the corticoadrenal gland which are oxygenated on carbon 11.

Indirectly this action may be caused by the adrenotropic hormone of the anterior pituitary.

One may then say that for the presence of antibodies in the blood two conditions are necessary, apart from the antigenic action: an adequate protein nutrition and an adequate function of the pituitary and adrenal glands.

If one now examines the tendency of the hypoproteinotic child to gastrointestinal disorders, especially to

F., and White, A.: Functional Alterations in Lymphoid Tissue Induced by Adrenal Cortical Secretion, *Ann. J. Anat.* 77: 81, 1945.

diarrhea, one may say that this tendency was recognized by Parrot³ in his description of "athrepsia" seventy years ago; he stated that "the initial fact is a modification of the feces which, more frequent and softer than normal, cease to be yellow and homogenous, to present white curdles and greenish striations."

He went on to say that "at the same time the quantity of the urine decreases and its color is darker, the thirst is more vivid and by its cries, the infant demands more frequently its satisfaction, but . . . notwithstanding the frequency of meals, the quantity of milk it drinks is less than the normal dosis."

Schweizer¹² also recognized this tendency to diarrhea as one of the characteristics of "dysontic" children, following the school of Bessau.⁴

What has happened is that, under the influence of the discoveries of Pasteur, physicians have a tendency to think of infection as the most common cause of gastrointestinal disorders of childhood, and in a natural way have been led to believe that gastrointestinal disorders are the cause and not the consequence of the nutritional disturbance.

It is true that diarrhea complicates the picture, bringing about the addition of undernutrition, malnutrition and dehydration to the original picture of hypoproteinosi, and even concealing this original disturbance under the more conspicuous signs of the added derangements, but the theory that, at least in some of the cases, diarrhea is not of infectious origin, but nutritional in character, is, to my mind, not only acceptable but highly probable.

These gastrointestinal upsets are a constant sign in cases of hypoproteinosi. Gómez Pagola¹³ has found them in 100 per cent of 500 cases studied by him in the Children's Hospital in México, D. F.

Infant mortality is higher in those regions of Mexico which are of low agricultural productivity, the highlands situated higher than 5,000 feet (1,524 meters) above sea level, while richer regions under 5,000 feet, though more favorable for tropical infections, have a lower infant mortality. The relation of poverty to infant mortality is thus clearly proved.

It seems highly probable that these gastrointestinal symptoms may be connected with a fatty liver.

Gillman and Gillman,¹⁴ of South Africa, have recently shown that children afflicted with "pellagra" do not react favorably to vitamin treatment, while administration of powdered stomach gives the best results. They have studied the degree of fatty infiltration of the liver in smears taken from biopsy specimens of liver and have been able to find a relation between the degree of infiltration and the severity of symptoms.

Fatty infiltration of the liver cell is an important consequence of hypoproteinosi. The amino acid methionine has been found to be indispensable for the synthesis of choline¹⁵ as a source of methyl groups or, as the process is now called, for transmethylation.¹⁶ Powdered stomach and powdered pancreas are rich in methionine.

The only criticism that can be made of the work of Gillman and Gillman is of the error of referring to these children as pellagrous patients. Pellagra is not the cause of this type of diarrhea and is not the chief underlying factor, but hypoproteinosi. Pellagra is a complication of the disease.

Parrot³ described in an impressive manner the picture of the later stages of athrepsia, a form of the disease in which dehydration is the most important feature or, as he said: "the organism suffers from aridity."

He described the excavation of the orbits, the depression of the fontanels, the bones of the skull mounting on one another, the lividity around the mouth and the imperfect closing of the eyelids, which enables one to see the diminished ocular globes, with their dull dry corneas and injected conjunctival membranes.

But nowadays dehydration is too well known not to be remedied, and one's attention is engaged more frequently with the opposite picture of generalized edema, which is usually accompanied with the symptoms of malnutrition, xerosis, pellagra and ariboflavinosis being the most frequent among the vitamin deficiencies.

Nevertheless, one still frequently sees a picture which, it seems to me, has many points of contact with Simmond's cachexia as produced in adults in cases of anorexia nervosa, which can be characterized as the bankruptcy of the organism.

One cannot but remember that Parrot described athrepsia as "nutrition in reverse" and that the anterior pituitary and the adrenal cortex are the agents for conversion of protein into glycogen: When this mechanism is exhausted, bankruptcy is declared.

Hypoproteinosi and dehydration are still often encountered together. Parrot used to say that "in order that the chemical phenomena of nutrition may take place, it is necessary that the internal medium be humid, that plasma may be abundant. The impoverishment of its plasma and, if it is permissible to say, its concentration, are accused by cyanosis and the relative increase of red blood cells. The blood dyscrasia is the capital feature of athrepsia."

When one now characterizes shock by blood concentration, just as Selye¹⁷ spoke of his "alarm reaction" as being the expression of shock, provoked by the exposure to stimuli to which the organism is not adapted, and of hunger as one of the most frequent causes of shock, one associates corticoadrenal insufficiency with the picture of dry hypoproteinosi.

One cannot but recognize the truth of the following words of Duncan¹⁸ in his book on "Diseases of Metabolism":

The reduction of the concentration of protein in the serum is an inadequate measure of the actual albumin deficit. As the albumin diminishes, the plasma volume shrinks, presumably because the protein osmotic pressure drops. As the process continues a compromise is, as usual, reached between plasma volume and protein concentration by the interaction of compensatory mechanisms. Analysis of the bodies of animals reveals the fact that the tissues are the greatest sufferers of all. Before serum albumin becomes sufficiently depleted, therefore, to cause edema, the tissues and organs throughout the body have been drained of protein. . . . The retention of 1 Gm. of nitrogen causes the organism to add 25 Gm. of weight, because 6.25 Gm. of protein will be formed from the gram of nitrogen and the protein will require and hold three times its weight of water.

When this compromise is reached, there still remain some symptoms of general dehydration. Chronic hypoproteinosis in children and in adults is revealed by dryness and scaliness of the skin, lack of tissue turgescence, cold extremities, increased viscosity of the blood and a tendency to low blood pressure rather than to edema and hypoproteinemia, which is a manifestation of acute hypoproteinosis such as may appear in circumstances of war as it was observed in Mexico in 1915 during the revolution.

The most probable factor in reaching this compromise is the function of the corticoadrenal gland of regulating water and sodium balance at a lower level.

This is usually reached at 6 years of age, when the child is said to be adapted to hypoproteinosis; the morbidity and mortality drop, except for some infections, such as rheumatic fever and tuberculosis, which still are a menace to him.

One then speaks of natural selection, but this does not exactly mean that those who survive are the stronger; it may mean a survival of those persons of lower food requirements.

The Indian will then survive and escape from hyper-tension, obesity, diabetes and coronary thrombosis in a despondent and hopeless life.

Special Article

CANCER OF THE BONE AND JOINT

DALLAS B. PHEMISTER, M.D.
Chicago

This article is the tenth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

The bones and joints are skeletal structures derived from the mesoderm, and cancers arising from them belong to the general class of malignant tumors designated as sarcomas. However, when the cancer is composed of a specific tissue or cell of the skeletal structure the name of that tissue or cell may comprise a part of the name of the tumor. Primary cancer of the bone differs so widely from primary cancer of the joint that the two lesions call for separate consideration.

CANCER OF THE BONE

Sarcoma of the Bone.—Sarcoma arises more frequently in the bone than in any other tissue or system of the body, and the frequency with which it is responsible for loss of limb or life makes it rank as the major problem of malignant tumors springing from the meso-elastic tissues. However, the relative incidence of sarcoma of the bone is extremely low in comparison with that of other disease, and the infrequency with which it is seen by the general practitioner makes for difficulty and much delay in diagnosis.

The etiologic basis of sarcoma of the bone is as obscure as that of malignant tumors in general, and little progress is being made toward a better under-

standing. This is in contrast with the significant modern advances that have been made in the pathology, diagnosis and treatment of the disease. While there is some variation with age according to class, sarcomas of the bone as a group occur principally during the first half of the life span and reach the high point of frequency between the fifteenth and twentieth years, according to the statistics of Christensen¹; the incidence declines gradually until only a rare case is encountered in the seventh or eighth decade. By way of contrast metastatic carcinoma is the common tumor encountered in bone during the second half of the life span, and its relative frequency increases with advancing age.

Males are somewhat more frequently affected than females. According to Christensen¹ the difference in frequency is limited mainly to the group of osteogenic sarcomas.

Little is known about heredity in sarcoma of the bone, but so far it has not been shown to play an important role. Sarcoma is seldom a part of the clinical picture in cancer families.

Certain benign tumors of bone, namely chondroma, cartilaginous exostosis and benign giant cell tumor, are predisposed to transformation into sarcoma.

Paget's disease of bone, osteitis deformans, sometimes leads to the development of sarcoma in one or more of the affected bones. Of 180 primary sarcomas of bone observed by Platt² 10 developed in patients with osteitis deformans.

Fibrocystic disease and osteodystrophia fibrosa are rarely complicated by sarcoma, and radical forms of treatment for the avoidance of malignant transformation are unwarranted.

The exciting cause of sarcoma of the bone remains unknown for the vast majority of cases. Trauma has long been considered an exciting cause and is still the subject of debate. Since sarcoma has often been noted following a single trauma the problem has been to determine whether the injury was the cause of the tumor or whether it precipitated symptoms and signs in a preexisting tumor. Careful studies including roentgenograms have revealed little evidence in support of the view that either single or multiple trauma is the exciting cause of sarcoma of the bone. Among the enormous number of fractures observed annually in which early roentgenograms reveal no change in the bone except the fracture, it is exceedingly rare to observe sarcoma of the bone as a sequel. Coley³ com-

mented on the fact that in courts of law the importance of trauma in the causation of sarcoma of the bone has been greatly overestimated.

Fig. 2 (case 1).—Posterior view of resected specimen: the central portion of the tumor is ossified, the peripheral portion is little ossified.

Fig. 3 (case 1).—Photomicrographs of sections from peripheral tumor showing (A) radiating ossified tumor and (B) unossified tumor; slightly reduced from magnification of $\times 125$ and $\times 800$, respectively.

The only definitely established exciting causes of sarcoma of the bone in man are roentgen radiation and radioactive elements. Hatcher⁴ recently collected from the literature 17 cases of sarcoma of the bone produced by roentgen radiation and added 3 of his own. Martland⁵ reported cases of sarcoma developing in radiation-damaged bones of dial painters, who repeatedly ingest minute amounts of radium, mesothorium and radiothorium, and demonstrated radioactivity in all the bones. Radiation from roentgen rays, natural and artificial radioactive substances⁶ and certain nonradioactive chemicals⁷ implanted in the bones have all produced sarcoma in experimental animals. Sarcoma of the bone promises to become an important health problem with the future development of atomic energy.

Distribution.—While any part of the skeleton may be involved, primary cancer is disproportionately more frequent in the bones preformed in cartilage than in those preformed in membrane. In general the larger the bone the greater the incidence, which means that the long bones of the limbs and the pelvis are the most frequent seats of neoplastic growth. The tumor nearly always begins in the shaft, and the ends of the shaft are much more frequently involved than is the midportion. Spread of the tumor to the epiphysis is common, but it takes place less readily in children than in adults because the epiphyseal cartilage plate acts as a barrier.

Varieties.—Primary cancers of bone vary greatly in structure, and no classification yet proposed has met with general acceptance. The stem cells of a bone may potentially give rise to malignant growths representative of each type of fixed cell or tissue that enters into its structure, excepting nervous tissue, which comes from without. Consequently classifications, as that of the Registry of Bone Sarcoma of the American College of Surgeons reported by Ewing, are usually based on a combination of cell and tissue types.

An analysis of the registry cases in 1939 revealed 1,437 primary bone cancers classified as follows: osteogenic sarcoma 895, or 62.3 per cent (6 parosteal); chondrosarcoma 110, or 7.6 per cent; periosteal fibrosarcoma 29, or 2 per cent; Ewing's sarcoma 238, or 16.5 per cent; myeloma 112, or 7.7 per cent; reticulum cell sarcoma 10, or 0.7 per cent; lymphosarcoma 19, or 1.3 per cent; malignant giant cell tumor 19, or 1.3 per cent.

per cent, and liposarcoma 5, or 0.3 per cent. This gives osteogenic sarcoma too high a percentage because of the inclusion of certain other tumors, as central fibrosarcoma, in that class.

By the designation of each variety according to the principal tissue or cell of which it is composed, the great majority of primary sarcomas of the bone may be fitted into the following classification, leaving a relatively small number of undifferentiated tumors unclassified: 1, osteogenic sarcoma; 2, chondrosarcoma; 3, fibrosarcoma; 4, malignant giant cell tumor or giant cell sarcoma; 5, Ewing's sarcoma (so-called endothelial myeloma); 6, reticulum cell sarcoma; 7, lymphosarcoma; 8, angiosarcoma; 9, liposarcoma, and 10, myeloma.

Osteogenic Sarcoma.—Osteogenic sarcoma is composed of cells which possess the property of producing bone. It is the most important of the bone sarcomas, since it comprises about one half of all cases and has a high mortality rate.

The tumor nearly always starts within the bone, replacing the medullary tissue and invading and eroding the cancellous bone. The cells form tumor bone which varies greatly in amount and in degree of differentiation. In some cases the bone is scanty; in others, abundant and dense; in some cases it is little differentiated,

in others it consists of well formed trabeculae. As growth continues the cortex is eroded and penetrated, and the sarcoma forms a mass on the surface of the bone. The periosteum may lay down new bone on the shaft beyond the limits of the tumor. In some cases the tumor outside of the bone ossifies to about the same extent

Fig. 5.—Partially ossified pulmonary metastases (A) from densely ossified osteogenic sarcoma of tibia.

and in the same manner as that within the bone. However, in other cases it ossifies much less extensively and the new tumor bone radiates outward from the cortex into the unossified portion. Cartilage sometimes forms in the process of ossification of peripheral osteogenic sarcoma just as in the process of ossification of peripheral callus. Osteogenic sarcomas cast characteristic shadows of bony density in roentgenograms. Some of the features are illustrated in case 1.

CASE 1.—A dentist, aged 26, for four months had had pain and toward the end of that period a slight swelling in the region of the upper shaft of the right humerus. A roentgenogram (fig. 1) revealed a pronounced increase in density within the head and upper shaft of the humerus, and rays of increased density extended laterally from the cortex into the external tumor (A). Osteogenic sarcoma was diagnosed. The deltoid muscle and the upper 15 cm. of the humerus and its muscular and capsular attachments were resected, and the defect was repaired with transplanted bone from the tibia. A posterior view of the resected humerus (fig. 2) revealed diffusely ossified tumor within the bone and fleshy tumor along the external surfaces laterally and posteriorly. Microscopic sections from the peripheral portion of the tumor (fig. 3) disclosed radiating tumor bone (A) and overlying unossified sarcoma (B). The patient has since remained well and has continued to do his dental work with the right arm. Figure 4 (eleven years after resection shows the recent roentgenologic appearance.

The external tumor may grow to great dimensions, and regional veins may be invaded even while the tumor is small. Metastases usually develop relatively early, but they may not grow to a size by which they can

be recognized for one or more years. The tumor spreads not only by way of the blood stream to the lungs, bones and other tissues but also not infrequently by way of the lymphatics to the regional lymph nodes. The metastases usually ossify if the primary tumor is decidedly ossified. Figure 5 illustrates the roentgenologic appearance of the lungs in such a case.

Chondrosarcoma.—Chondrosarcoma of bone consists, in the greater part or all of its extent, of cartilage showing varying signs of differentiation and other signs of cancerous growth. Clinically it simulates osteogenic sarcoma in many respects but usually runs a more chronic course and frequently casts characteristic shadows in roentgenograms. A soft cartilaginous tumor begins centrally and erodes cancellous bone and inner portions of cortex. There may be little or no surrounding formation of new bone, so that roentgenologically the lesion resembles other osteolytic tumors, bone cysts and granulomas. However, if the thicker portion of the shaft becomes involved both periosteal and endosteal new bone are laid down to form a thick expanded shell

Fig. 6 (case 2).—Central chondrosarcoma with thickening of surrounding bone.

Fig. 7 (case 2).—Photomicrograph of slightly differentiated chondrosarcoma (A); eroding cortex (B). Somewhat reduced from a magnification of $\times 125$.

about the central soft tumor. Roentgenologically this casts a thick, dense shadow surrounding

central radiolucent area which is highly suggestive of a chondrosarcoma, as in the following report of a case:

Fig. 8 (case 2).—Bone graft reconstruction after ten and one-half months (A) and seven years (B).

CASE 2.—A girl aged 11 had undergone an operation for painful central cartilaginous lesion of the lower part of the right femur sixteen months before admission; there was recurrence of pain four months ago. Figure 6 shows the roentgenographic appearance. Fifteen centimeters of the shaft were resected, and the defect was repaired by two tibial bone grafts. An embryonal type of cartilage filled the central cavity and eroded the bony wall (fig. 7). The diagnosis was chondrosarcoma of low grade malignancy. The girl has remained well for seven and one-fourth years, and figure 8 portrays the femoral repair after ten and one-half months (A) and seven years (B).

Other cases of central tumor may reach large size, and blotchy islands of calcification and ossification may appear within the cartilage. They cast characteristic blotchy, dense shadows (fig. 9). Even more characteristic are the disconnected, irregular, dense shadows seen in roentgenograms of peripherally situated chondrosarcomas which contain islands of calcification and ossification.

Fig. 9.—Advanced central chondrosarcoma with blotchy ossification within (A) and thick shell surrounding new bone (B).

CASE 3.—A boy aged 14 had a chondrosarcoma of the tibia (fig. 10 A). Amputation of the thigh was performed, and tumor (B) was found to have grown into the femoral vein.

This is not uncommon in the advanced stages of chondrosarcoma, and cartilaginous pulmonary and lymph node metastases may develop.

Fibrosarcoma.—Fibrous tissue is a constituent of the marrow as well as of the periosteum; fibrosarcoma of bone may begin in either structure. Contrary to previously held views, fibrosarcoma is much more frequently primary in the medullary region than in the

periosteum. In the extremities it usually begins in the cancellous portion of the end of the shaft and gradually destroys and replaces both medullary and cortical structures. The tumor tissue never forms tumor bone. After perforation of the cortex an oval mass forms along one side of the bone, and the adjacent periosteum may lay down small amounts of new bone. Pathologic fracture is not uncommon at this stage.

Microscopically the tumor usually consists of spindle cells and a more limited number of round cells with collagen fibers in the matrix and nuclear evidences of cancer. Necrosis is common. Roentgenograms usually reveal extensive reduction in density in the central region and irregularly reduced density of portions of the cortex. There is no shadow of new bone within the tumor, but there may be shadows of periosteal new bone along the surface of the adjacent shaft.

CASE 4.—A woman aged 50 had a painful right knee of one year's duration and a palpable swelling over the back of the lower end of the femur. Figure 11 shows the roentgenologic appearance and figure 12 a large microscopic section of the

Fig. 10 (case 3).—A, chondrosarcoma of tibia with dense blotchy islands of ossification and calcification in peripheral tumor and B, cartilaginous tumor removed from femoral vein during amputation of thigh.

involved bone which was removed when massive resection of the region was performed. The defect was repaired by two massive tibial bone grafts. The central portion of the tumor was extensively necrotic and the surviving portions consisted of a spindle cell tumor (fig. 13). Twenty-one months have elapsed since the surgical operation, and there are no signs of local recurrence or metastases.

Spindle cell fibrosarcoma of varying grades of malignancy may arise in the periosteum and produce an oval swelling with little tendency to invade the underlying bone. Ewing⁹ emphasized the remarkable tendency for some of these tumors to produce multiple metastases in the periosteum of other bones.

Fibrosarcoma usually pursues a clinical course somewhat less malignant than that of osteogenic sarcoma. But in most cases metastases, often not detectable clinically, are present before treatment is initiated and the disease ends fatally months or years later.

9. Ewing, J.: A Review of the Classification of Bone Tumors, Surg., Gynec. & Obst. 68: 971, 1939; Neoplastic Diseases: A Treatise on Tumors, ed. 4, Philadelphia, W. B. Saunders Company, 1940.

Malignant Giant Cell Tumor or Giant Cell Sarcoma.—Benign giant cell tumor of bone is relatively common, whereas malignant giant cell tumor is rare. The registry in 1939 contained 238 benign giant cell tumors as against the 19 cases that were malignant. Both benign and malignant forms occur most frequently between the ages of 15 and 40 years, and in the limb bones they involve both the end of the shaft and the epiphysis.

Most giant cell tumors that terminate as cancers appear to be initially benign. They produce chronic pain in the region of the joint and later a swelling on one side of the bone. Roentgenograms reveal a sharply circumscribed central area of reduced density beginning usually in the metaphysis and extending into the epiphysis, and there is no shadow of reactionary new bone. Under the diagnosis of a benign tumor the lesion is removed with the curet and often the cavity is filled with bone grafts. Pathologic examination confirms the diagnosis of a benign lesion, but in the course of months or years there is recurrence of pain and tumor and roentgenograms exhibit more ragged destruction of bone. At a subsequent operation the diagnosis of cancer is established.

In a minority of cases the initial tumor grows more rapidly and produces an external swelling with irregular

osseous destruction or a triangular layer of new bone in the neighboring periosteum, suggestive of cancer. Pathologic examination after biopsy or curettage establishes the diagnosis of cancer.

Grossly, a benign lesion may be chocolate colored while a malignant one is grayish and mottled. The two types of tissue may be seen in the same specimen when cancer has appeared as a secondary change in a benign tumor. Giant cell sarcoma is nearly always nonossifying. Microscopically it contains giant cells, most of which are of small size, and occasionally a hyperchromatic or dividing nucleus is seen. The mononuclear cells are greatly in excess and in most of the extent of the lesion, and some show hyperchromatic nuclei or various stages of cell division.

In the following case a primary benign giant cell tumor early presented evidence of a low grade cancer.

CASE 5.—A man aged 26 had increasing pain and disability in the left knee for six months and a recent swelling of the mesial condyle. A roentgenogram (fig. 14) showed a sharply outlined reduction in density of the condyle resembling a benign giant cell tumor, but there was a triangular shadow of new bone (C) on the cortex above, an observation more frequently made in cancer. A biopsy confirmed the diagnosis of cancer, after which a massive resection of the region was performed and the defect repaired with two large tibial grafts. A section

Fig. 12 (case 4).—Large microscopic section of resected femur showing tumor with central degeneration.

Fig. 13 (case 4).—Fibrosarcoma, magnification $\times 475$.

late-colored portion (fig. 15), which was composed of giant cells in a stroma containing round and oval mononuclear cells, appeared benign. The mottled gray portion (fig. 16) was composed of comparatively few giant cells and large numbers of spindle cells with oval nuclei. Occasional mitotic figures and numerous hyperchromatic nuclei were present. The patient

lary cavity, grows at varying rates and destroys bone, but its cells never produce bone. On nearing the surface it usually stimulates the periosteum to form considerable bone but the amount may be small, especially in adults. Pathologic fracture is not uncommon in neglected cases. Widespread metastases in bone may destroy so much marrow that severe anemia is produced. Roentgenograms reveal reduction in density from wormeaten destruction of cancellous and cortical bone and a surface layer of increased density from the periosteal new bone. Metastases produce conditions similar to those of the primary tumor.

The tumor responds well to initial roentgen treatment, but there is recurrence in a high percentage of cases and this, with the frequent metastases, produces a fatal termination.

Fig. 14 (case 5).—Roentgenogram and microscopic section of giant cell tumor of the femur: lateral portion benign (A); mesial portion malignant (B); triangle of periosteal bone (C).

has remained well. A roentgenogram (fig. 17) shows the recent appearance of the lesion five and three-fourths years later. The long period of survival raises the question of a borderline tumor, despite the microscopic appearance of cancer.

Ewing's Sarcoma (Round Cell Sarcoma of Uncertain Origin).—Ewing⁹ separated from the poorly differentiated malignant growths of bone a tumor which he

Fig. 16.—Sarcomatous mesial portion (B) of giant cell tumor.

Fig. 15 (case 5).—Benign-appearing tumor, magnification $\times 300$.

thought consisted of angioendothelial cells and which he designated as endothelial myeloid tumor is frequent in children of the bones of the trunk and of the extremities and is prone to metastases in bone. It is an early adult frequently produced in the medul-

Ewing described the tumor as consisting of small polyhedral cells with pale cytoplasm, a small hyperchromatic nucleus and a definite cell border. In some cases tumor cells were thought to line vascular spaces, but other observers have regarded this appearance as due to survival of perivascular cells in degenerating portions of the tumor. Figure 18 shows the usual roentgenologic picture; figure 19 portrays the character of the cells in Ewing's sarcoma. Well preserved cells have an ill defined border, scanty cytoplasm, a relatively large nucleus and scattered chromatin.

Much confusion exists concerning this and kindred tumors of bone marrow, and many authors deny the endothelial origin of any of them. In the opinion of Oberling Ewing's tumor comes from the supporting mesenchymal cells of the bone marrow and is a reticulosarcoma. According to Stout it is a derivative of the mesenchymal supporting framework of the bone marrow a variant of reticulum cell sarcoma. By Lichtenstein and Jaffe it was regarded as a sarcoma derived from primitive marrow connective tissue without further

specification. Willis pointed out that osseous metastases from neuroblastoma arising in the adrenal medulla or in sympathetic nerve ganglions located elsewhere have often been wrongly diagnosed as Ewing's sarcoma. This accounts for a part of the exceedingly high mortality usually given. Further study is necessary before the slightly differentiated malignant growths arising in the medullary cavity can be classified properly.

Reticulum Cell Sarcoma.—Primary reticulum cell sarcoma is a nonossifying, bone-destroying tumor derived from embryonal reticular tissue of the marrow and characterized by an unusually favorable response to surgical treatment.

It affects both long and flat bones and grows to a large size, first within the medullary region and later outside the shaft. The tumor is gray to red, erodes the bone, stimulates the periosteum to form new bone and becomes necrotic in its deeper regions. Grossly and microscopically it bears some resemblance to Ewing's tumor, with which it is often confused.

The tumor consists of round, oval and elongated cells, which are somewhat larger than lymphocytes. The nucleus is relatively large and oval, and nucleoli are sometimes prominent. The stroma contains both collagen and reticulum fibers, and cytoplasmic processes are present.

Metastasis, loss of weight and cachexia appear relatively late, and amputation or wide local resection, in case of trunk bones, gives strikingly good results. Of Parker and Jackson's¹⁰ group of 17 treated principally in this way 7 were free from signs of the disease ten or more years afterward.

CASE 6.—A man aged 23 had a reticulum cell sarcoma (fig. 20). An amputation through the upper part of the thigh was performed one year after the onset. Figure 21 gives the microscopic characteristics of the

Fig. 17 (case 5).—Roentgenogram five and three-fourths years after bone graft repair of defect.

tumor. The patient is now free from signs of tumor thirteen years afterward.

Lymphosarcoma.—In some cases of lymphosarcoma the bones have been the seat of the first lesion to be detected. The tumor is painful and produces central destruction with little or no accompanying new bone. Microscopically the cells consist of malignant lymphocytes in a stroma containing both collagen and reticulum fibers. This has led to an endeavor to establish primary lymphosarcoma of bone as a separate entity. Wieland¹¹ discussed a series of such cases as possible myelomas but preferred to regard them as reticulum cell lymphosarcoma. Craver and Copeland¹² reported several patients with multiple lymphosarcomatous bony lesions who later had extension of the process to the lymph

nodes, thereby completing the clinical and pathologic picture of a reticulum cell lymphosarcoma. In view of the regular appearance of lesions in both the bone marrow and the lymph nodes and the frequent multiple osseous foci, it appears advisable to classify all lymphosarcoma as a disease of the lymphatic system and not to recognize a variety of primary lymphosarcoma of bone which gives rise to metastases in the lymph nodes.

Angiosarcoma.—If Ewing's tumor is excluded because of its nonendothelial nature, angiosarcoma (telangiectatic sarcoma or malignant bone aneurysm) is left as the only sarcoma of the bone which is of vascular origin. It is a rare tumor which is most frequent in childhood and adolescence; it begins in the medullary cavity, grows rapidly, erodes the bone (which is replaced by large blood sinuses) and elevates the periosteum, often creating thereby a blood-filled sac lined by tumor. The peripheral portion consists of reddish tissue which microscopically is composed of hyperchromatic

Fig. 18 (case 8).—Ewing sarcoma producing metaphyseal bone destruction and periosteal new bone.

Fig. 19.—Ewing sarcoma, magnification $\times 1,135$.

spindle and polyhedral cells, with numerous small blood sinuses scattered throughout and lined by tumor cells. The tumor reaches large size, frequently causes fracture, metastasizes to the lungs and produces death in the course of several months.

12. Craver, L. F., and Copeland, M. M.: Lymphosarcoma in Bone, *Arch. Surg.* 28: 809 (May) 1934.

Liposarcoma.—Only a few cases of liposarcoma have been described as arising from the fat tissue of the bone marrow. Stewart¹³ and Rejbock and Hauser have reported bone-destroying tumors with malignant characteristics which give rise to metastases in the lungs and in other bones. Microscopically their structure resem-

Fig. 20 (case 6).—Reticulum cell sarcoma with extracortical extension mesially (A) and mottled central necrosis (B).

bles liposarcoma in other locations. Additional cases have been reported recently by Khanolkar¹⁴ and Williford and Fatherree.¹⁵

Myeloma.—Myeloma is a malignant tumor of hemopoietic elements of the bone marrow, usually appearing multifocal in origin. It is seen principally in adult life to be beyond the age of 30, and men are about twice as frequently affected as are women. The lesions first to cause pain are most frequently located in vertebrae, ribs, pelvis, femur and humerus. They produce small to large punched areas of osseous destruction which gradually become confluent. Little or no new bone is formed. There is loss of weight, anemia and general debility as the disease advances; fractures may occur, leading to deformities.

The tissue of the tumor is soft and grayish to brown according to vascularity. The main varieties in order of frequency are plasma cell myeloma, myelocytoma, lymphocytoma and erythroblastoma. Bence-Jones albumosuria and hyperproteinemia are present in the majority of the patients. Roentgenograms which exhibit the multiple punched areas of reduced density are of diagnostic importance, as illustrated in a case of plasma cell myeloma in a man aged 40 (figs. 22 and 23). Sternal puncture usually yields myeloma cells, or a biopsy may be necessary in order to confirm the diagnosis.

Solitary myeloma usually becomes multiple, but it may persist as such for long periods or be controlled indefinitely by roentgen therapy without the appearance of other lesions. Roentgen therapy should also be used in multiple myeloma, as it relieves pain and prolongs life.

Diagnosis.—The diagnosis of sarcoma of the bone is generally based on a history of chronic recurrent pain and, sooner or later, the appearance of a deep seated bony swelling. Since in the extremities it is usually near a joint the condition is most frequently mistaken for rheumatism. Roentgenograms taken during this stage reveal changes which are either highly

suggestive or diagnostic of sarcoma. However, before either surgical or radiation therapy is started the diagnosis should be confirmed by biopsy.

Osteogenic sarcoma casts amorphous shadows of increased density in the medullary region, in which it has invaded and replaced old bone. More or less radiating shadows of bony density are cast along the surface of the shaft if the sarcoma has broken through the bone.

Chondrosarcoma may frequently be recognized by the presence of blotchy shadows of increased density or a thick cortical shadow of increased density surrounding a central zone of reduced density.

Medullary fibrosarcoma produces an irregularly outlined central shadow of reduced density and, if it has broken through the cortex, a peripheral shadow of faint density. There is relatively little periosteal new bone casting dense shadows along the surface.

Malignant giant cell tumor usually progresses more rapidly and produces more pain than the benign form, and in roentgenograms the bony margin may show ragged reduction in density resembling fibrosarcoma and osteolytic metastatic carcinoma.

Ewing's sarcoma, with its irregular reduction in density of old bone and varying amounts of increased density peripherally from periosteal new bone, may simulate chronic inflammation and metastatic tumors as well as other forms of sarcoma of the bone. Onset in early life and early metastases are points suggestive of Ewing's sarcoma. Lamellated periosteal shadows are sometimes present but not characteristic.

Reticulum cell sarcoma produces local changes similar to Ewing's sarcoma but occurs in a somewhat older age group, runs a slower course and is much more favorably controlled by surgical procedures.

Angiosarcoma infiltrates and destroys bone, producing roentgen ray shadows of reduced density. It metastasizes

Fig. 21 (case 6).—Reticulum cell sarcoma, magnification $\times 940$.

sizes early and runs a rapidly fatal course, but a biopsy is necessary to make the diagnosis.

Multiple myeloma is usually first suspected from multiple punched out areas of reduced density observed in roentgenograms which were made because of pains in the bones in the absence of tumor. They simulate the picture of osteolytic metastases produced by carci-

noma, especially from the breast. The diagnosis is usually confirmed by the observation of Bence-Jones albuminuria and hypoproteinemia, which are seldom present in solitary myeloma.

In the final analysis there are some cases in which the diagnosis remains uncertain and others in which

Fig. 22.—Humeral and scapular lesions (A) in multiple plasma cell myeloma.

one must be contented with the diagnosis of cancer without knowledge of the exact variety. *Treatment.*—The treatment of a sarcoma of the bone, in the absence of demonstrable metastases, should be by wide resection or excision of the involved bone, if it is located in the trunk or head and lends itself to such an operation. If located in an extremity the treatment should usually be by amputation at a level well above the upper limits of the tumor.

If the sarcoma of a long bone is located in the lower one third, amputation should be either through or above the upper one third; and if in the upper one third the amputation should be above the proximal joint or sometimes through it, as in case of the hip. Excision of the regional axillary or inguinal lymph nodes is an additional safeguard, not extensively practiced at present. Supplementary radiation therapy, both local and regional, is more frequently used.

The average mortality for all varieties of sarcoma of the bone that have been treated along these lines is high. Metastases frequently develop and local recurrence is not rare. Long term statistics of a large series of well studied cases are sadly lacking, but less complete information indicates that the five year survivals are under 15 per cent and that a fair percentage of these are permanently cured. The mortality for angiosarcoma, osteogenic sarcoma and Ewing's sarcoma is notably high, while that of chondrosarcoma and reticulum sarcoma is definitely less so.

Irradiation is the treatment of choice in case of sarcoma of the bone which is so located that surgical treatment cannot be employed or which has produced demonstrable distant metastases. Ewing's sarcoma, lymphosarcoma, reticulum cell sarcoma and metastatic cancer usually respond favorably to treatment but sooner or later recur and become radioresistant. Embryonal chondrosarcoma also responds favorably and may be held in check for prolonged periods. Osteogenic sarcoma responds extremely poorly, and it is rare to see a case in which prolonged palliation is obtained.

A selected group of sarcomas of the long bones of the lower grades of cancer and relatively small size may be treated by extensive resection of the involved bone and adjacent soft tissues and repair of the skeletal defect by massive transplantation of bone. Experience has shown, as in the 3 cases shown in figures 1 to 4, 6 to 8

and 14 to 17, that a useful extremity may thereby be preserved. The incidence of local recurrence is only slightly to moderately increased over that which follows amputation, and the incidence of distant metastases is only increased to the extent that they may spread from a possible local recurrence. From my limited experience the most favorable types for such treatment are chondrosarcoma, giant cell sarcoma and reticulum cell sarcoma (1 patient who had reticulum cell sarcoma remains well seven and one-third years after resection of 17 cm. of the shaft of the femur, with subsequent reconstruction by transplantations of bone). Blood transfusion, tourniquet hemostasis and antibiotics have rendered these, as well as other extensive operative procedures more feasible. One of the most important future advances in the surgical treatment of sarcoma of the bone should come from the judicious employment and expansion of local resection.

CANCER OF THE JOINT

Primary cancers of the joint are rare, there being fewer than 150 cases in the literature. They have been variously designated as synovioma, synovial sarcoma and cancerous synovial tumor. Giant cell and xanthomatous tumors of joints almost never undergo malignant change.

Synovial sarcomas occur especially in young adults and seldom after the age of 40 years. Haagensen and Stout¹⁶ found that there are 3 men affected to every 2 women. A relatively large number of cases were encountered among the Armed Forces during the late war, as reported by Bennett.¹⁷ The region of the knee is the seat of the tumor in nearly half the cases, the ankle, hip, tarsus and elbow being the other frequent locations.

The lesion begins in or about some portion of the synovial tissue as a painful swelling and may progress slowly over a period of years before either the presence of a tumor or the severity of the pain causes the patient to seek medical aid. The swelling is either confined to the region of the joint or extends distally or proximally in the adjacent soft tissues. Occasionally it invades and erodes the bone. Because of the pain, operative intervention is frequently performed while the tumor is small. It is found to be grayish or bluish

Fig. 23.—Plasma cell tumor in multiple myeloma (same case as figure 22).

and may adhere to surrounding tendons, muscles or bone. Microscopically it consists of a variety of cells which are variously arranged. This is because the

16. Haagensen, C. D., and Stout, A. P.: Synovial Sarcoma, *Ann. Surg.* 120: 826, 1944.

17. Bennett, G. A.: Malignant Neoplasms Originating in Synovial Tissues, *J. Bone & Joint Surg.* 29: 259, 1947.

synovial lining originates from the same mesenchymal tissue which produces the capsule and articular cartilage. Most of the cells are spindle shaped and arranged in sheets. Epithelial-like cells frequently form alveoli in a stroma of spindle cells. Synovial membrane patterns, bone and cartilage are sometimes present. Mytotic figures are inconspicuous except in the late stages.

After local excision the tumor frequently recurs, progresses rapidly and gives rise to metastases. Roentgenograms of the joint seldom reveal changes of bone or joint, but bone formed in the tumor may cause blotchy, dense shadows. The performance of biopsy is of great importance in the establishment of the diagnosis. Despite the slow course of the disease, the prognosis is extremely unfavorable. Of 104 patients whose cases were reviewed by Haagensen and Stout, only 3 were alive and free from metastases five years after the start of treatment.

Very wide excision is the treatment of choice when the disease is recognized in the early stage. This may involve sacrifice of tendon, muscle, capsule and even bone with ankylosis of the joint. Amputation is the treatment in the later stages.

Clinical Notes, Suggestions and New Instruments

MEDIASITINIS DUE TO INGESTION OF GLASS

JOHN D. STEELE, M.D.
Milwaukee

Considering that the glass industry produced over seven billion glass food containers during the year 1946,¹ it is surprising that accidents due to the ingestion of pieces of glass broken off these containers have rarely been reported.

I am reporting the cases of 2 small children, in each of whom mediastinitis developed after ingestion of glass chipped off baby food containers. These accidents occurred within a three week period. In both instances it is probable that the breakage of the containers was due to the improper exertion of force at one particular point in prying the covers off the vacuum-packed glass containers. However, it is probably not generally realized by the consumer that such force should be exerted at more than one point about the rim of the container and that directions for opening such containers, even though printed in extremely small type, could well be followed if similar accidents are to be avoided. Careful inspection by mothers of the rims of such containers after opening should be a routine procedure.

The importance of the early recognition of the complications of such accidents by physicians is obvious. Particular attention should be paid to the discovery of residual defects in baby food containers in cases in which the ingestion of a foreign body is suspected.

REPORT OF CASES

CASE 1.—History.—D. D., aged 18 months, was admitted to Milwaukee Children's Hospital on Dec. 21, 1946, at 5 p. m., with the following history: On the previous day, at 4:30 p. m., the child's mother had pried the metal lid off a glass container of baby food, using the back of a knife. After eating the contents of the jar, the child cried and gagged, and blood was noticed coming from the mouth. At 9 p. m. on the same day, it was noted that the child had a fever. It was then discovered that a piece of glass had been chipped off the rim of the glass container which had contained the baby food.

Physical Examination.—The child appeared toxic. He evidently had pain when attempts were made to move his head. Temperature was 102.4 F.

Roentgenologic Examination.—Lateral and oblique views of the neck revealed a radio-opaque foreign body in the region of the esophageal orifice. The retroesophageal space in the neck and mediastinum was definitely widened and contained gas.

Hospital Course.—One and one-half hours after admission, anesthesia was induced with ether and the pharynx and esophagus were explored with a direct laryngoscope and an esophagoscope. No foreign body was found. A shallow laceration was noted in the right anterior tonsillar pillar and a deeper laceration in the left pyriform fossa. It was concluded that the foreign body had perforated through the latter. A cervical mediastinotomy was then performed on the left. Definite, thin pus was encountered posterior to the esophagus. A Penrose sheath was inserted into the mediastinum for drainage. A cursory search of the retroesophageal space failed to reveal the foreign body. Because of the relatively poor condition of the child, an extensive search was not made at this time.

Subsequent culture of the pus revealed hemolytic staphylococci, nonhemolytic streptococci and a long aerobic gram-negative bacillus.

The child's postoperative course was stormy, being complicated by a thrombophlebitis of the left leg which followed the administration of intravenous fluids. Since the child was able to swallow fluids only with difficulty, feedings were administered by gavage until the sixth postoperative day, when formula appeared on the dressings on the neck. Fluids were then administered intravenously, and later there was oral administration of a mixture of "amigen" and glucose. Temperature returned to normal on the fourteenth postoperative day.

The patient received 400,000 units of penicillin, intramuscularly, per day from the day of admission until the eleventh postoperative day and 0.5 Gm. of streptomycin, intramuscularly, per day from the sixth to the eleventh postoperative day.

Roentgenologic examination of the tissues of the neck on December 30 revealed the foreign body posterior to the larynx at the level of the fourth cervical vertebra. On Jan. 3, 1947, the thirteenth postoperative day, under fluoroscopic control, a forceps was inserted through the wound in the neck and the foreign body grasped and withdrawn from the retroesophageal space. The foreign body proved to be a piece of glass having extremely sharp ends and edges, measuring 13 mm. in length and 6 mm. in width. This fragment exactly fitted the defect in the baby food container (see figure).

The patency of the fistula from the pharynx to the retroesophageal space was followed by the administration of dye by mouth and its appearance on the dressings. Since no dye appeared on the eighteenth postoperative day, normal feedings were resumed. The child was discharged from the hospital on January 11, the twenty-first postoperative day, at which time the wound in the neck was nearly healed. Two days after discharge, after ice cream had been eaten, a small amount of white fluid was noted to come from the wound in the neck. Drainage was noted after liquid feedings for the next week, after which the wound healed solidly.

CASE 2.—History.—R. R., aged 15 months, was admitted to Milwaukee Children's Hospital on Jan. 11, 1947, at 9:30 p. m., with the following history: Two days before, at noon, the child's mother had pried the metal lid off a glass container of baby food, using a "hook" type of opener. After eating part of the food, the child cried and blood was noticed coming from the mouth. Soon afterward the mother noticed that a piece of glass had been chipped off the rim of the glass container. The defect measured 15 mm. in length and 6 mm. in width and was exactly the same shape as the defect in the container in the case of D. D. The following day the child had a temperature of 102 F.

Physical Examination.—The child appeared toxic. Respirations were labored. Mucopurulent secretions were present in the nose and pharynx. Temperature was 103.6 F.

Roentgenologic Examination.—Anteroposterior and lateral views of the neck and thorax revealed a decided widening of

the retrotracheal and upper mediastinal spaces. The retrotracheal space (in the lateral view) measured 3.4 cm. instead of the normal of about 1 cm. This space contained a considerable amount of gas. There was no definite evidence of a foreign body.

Hospital Course.—Three hours after admission, anesthesia was induced with ether. The pharynx was then explored with a direct laryngoscope, and a definite laceration was noted in the posterior pharyngeal wall about 2 cm. below the uvula. No further endoscopy was performed at this time because of the child's respiratory difficulty, which was of an obstructive type. Just as an incision was to be made for a cervical mediastinotomy, the child's respirations stopped. A 4 mm. bronchoscope was immediately introduced into the trachea, the lumen of which was found to be greatly compressed, the lower portion being narrowed to a slit, the greatest width of which was not over 3 mm. As soon as the bronchoscope was passed through this slit, definite respiratory exchange was noted on manual compression of the thorax. Normal respirations were soon resumed. With the bronchoscope in the trachea, a cervical mediastinotomy was then performed on the left by Dr. Paul Hausmann. When the retroesophageal space was entered, a large amount of foul

SUMMARY

Two cases of mediastinitis in children are reported. Both followed the ingestion of baby food from containers from which glass had been chipped when the containers were opened. One case was proved to be due to the ingestion of the glass fragment, while the other was presumably due to the same type of fragment.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

THE CONTINENTALAIR ICELESS OXYGEN TENT WITH AUTOMATIC TEMPERATURE CONTROL ACCEPTABLE

Manufacturer: Continental Hospital Service, Inc., 18636 Detroit Avenue, Cleveland 7.

The Continentalair Iceless Oxygen Tent with Automatic Temperature Control is designed to provide an oxygen-enriched atmosphere for therapeutic purposes. When plugged into an electric outlet and equipped with a tank of compressed oxygen, it delivers a cooled and filtered gaseous mixture into the tent. The mixture may consist of oxygen from the tank plus recirculated air from the tent; the mixture is moved by a fan driven by a motor. There is also a compressor motor which accomplishes the refrigeration. The refrigerant is dichlorodifluoromethane ("freon").

The apparatus was examined in a clinic acceptable to the Council on Physical Medicine.

Hoods.—The material used to make the hoods is left to the discretion of the purchaser. About 80 per cent of hospitals today use transparent chlorinated rubber film made to fit the tent; this material may be disposed of economically. Another type of hood is made of fabric with plastic windows. These materials are fire resistant but in the presence of oxygen are highly inflammable. The hoods display a "no smoking" sign.

Operation.—(a) Circulation of Air: The blower is apparently satisfactory. There is no demonstrable tendency for stagnation of areas of the tent's atmosphere, yet no air currents are perceptible to the patient.

(b) Cooling: The refrigeration unit is efficient and extremely convenient. It is the outstanding feature of this apparatus. The temperature can be reduced easily to suit the comfort of the patient. In a room temperature of 92 F. and with the tent exposed to direct sunlight, the temperature in the tent was reduced to 72 F. in thirty minutes. The temperature in the tent does not correspond to the dial setting (in this instance, 60 F.) under such circumstances, but under more favorable conditions the temperature in the tent is usually within 2 to 5 degrees of the dial setting.

(c) Oxygen Concentrations: The oxygen concentrations were found to be comparable to those of other oxygen therapy tents. The concentrations vary widely, chiefly as the result of air contamination through leaks. Only ordinary precautions were taken to prevent such leaks during these investigations. Oxygen flows of 5 to 8 liters per minute produced oxygen concentrations of 30 to 40 per cent; with an oxygen flow of 15 liters per minute, the maximum concentration observed was 57 per cent.

(d) Carbon Dioxide: No significant accumulation of carbon dioxide within the tent was detected, even when a flow of oxygen was not introduced. Run as an "allergy chamber" without adding oxygen, carbon dioxide did not accumulate above 0.5 per cent and in one test was 0.2 per cent at the end of an hour. In such circumstances concentrations of oxygen varied between 19.3 and 19.6 per cent.

The atmosphere containing oxygen circulates through a sealed chamber, and danger of combustion from sparking of the electrical apparatus should be minimal.

The Council on Physical Medicine voted to include the Continentalair Iceless Oxygen Tent with Automatic Temperature Control in its list of accepted devices.

Drawing of glass baby food container showing piece of glass chipped off rim of container at time of opening. Glass chip ingested by child (case 1) and subsequently removed from retroesophageal space.

pus escaped under pressure. A large Penrose sheath was inserted well down into the mediastinum for drainage. On release of the pus from the mediastinum, the lumen of the trachea was observed to return to normal, the bronchoscope then being withdrawn.

Subsequent culture of the pus revealed staphylococci, streptococci, *Hemophilus influenzae* and a long aerobic gram-negative bacillus.

The child's postoperative course was satisfactory, the temperature returning to normal on the seventh postoperative day.

The patient received 600,000 units of penicillin, intramuscularly, per day from the day of admission to the sixth postoperative day and 0.5 Gm. of streptomycin, intramuscularly, per day from the third to the sixth postoperative day.

Roentgenologic examination of the tissues of the neck, mediastinum and abdomen on January 7 failed to reveal any evidence of an opaque foreign body. It was concluded, therefore, that the piece of glass had passed through the gastrointestinal tract after perforating the pharyngeal wall.

Healing of the wound in the neck was satisfactory and at no time was leakage of food observed on the dressings. The child was discharged from the hospital on January 31, the nineteenth postoperative day.

SLUDGED BLOOD

In a report representing sixteen years' direct study of the circulating blood, Knisely and associates¹ tell of observations on organs of experimental animals and on the bulbar conjunctivas of healthy and diseased human subjects. Studies of living organs were made in frogs, mice, rabbits, dogs, monkeys and other laboratory animals. Parts of organs were transilluminated by light-conducting fused quartz rods and were studied under the microscope with a magnification of sixteen to six hundred times. Structure, dimensions and behavior of blood and blood vessels were observed. Studies in human subjects were made on unanesthetized bulbar conjunctivas with binocular dissecting microscopes, using oblique illumination of universal slit lamps or ophthalmoscope light.

In healthy animals and human beings Knisely and his co-workers concluded that circulating red blood cells are not agglutinated but tend to repel each other slightly. Rouleau formation does not take place in carefully handled tissues. The normal red blood cells were not coated with any visible protein precipitate. Neither red nor white cells were observed clinging to the walls of small vessels. Inner surfaces of small vessels were smooth and clean. The flow of unagglutinated blood was streamlined, and the cells were arranged in concentric laminae. Pictures of normal blood flow were recorded cinematographically. From animal studies the authors concluded that the rate of flow of blood through each tissue of the body sets the maximum rate at which cells of that tissue can receive oxygen and other blood-borne materials. The small normal vessels of most tissues and organs were not observed to leak any appreciable amounts of fluid. The blood flowed so rapidly in most arterioles and venules ranging from 60 to 120 microns in diameter that the individual red cells could not be seen. The authors considered this a crude but accurate and useful criterion for adequate rates of flow through tissues and capil-

laries. "If the rates of flow of oxygen-saturated arterial blood are fast enough so that individual unagglutinated blood cells cannot be seen in vessels of this size in normal animals and man, high magnifications show that no hemoconcentration is taking place in capillaries (i. e., no blood fluid is being lost through the walls of the tissue capillaries)." In their observations of vessels the authors found that almost every arteriole-to-capillary or sinusoid-to-venule pathway can contract tightly throughout its length, making the inner diameter zero and thus forcibly preventing the entrance of blood. Most capillaries can dilate without losing tonus but not much more than two or two and one-half times the diameter of the animal's own red blood cells.

In the livers of frogs and rhesus monkeys the normal naked red blood cells slide and bump along the surfaces of the highly phagocytic cells which line the hepatic sinusoids but "no normal red cells have ever been observed to be ingested."

Having made the foregoing observations in normal animals and persons, the authors then turned to the examination of conjunctivas of 600 human patients in whom practicing physicians had diagnosed a wide variety of pathologic conditions. In large numbers of patients the diagnoses included many of the common acute and chronic inflammatory diseases of body organs such as the lungs, heart, gastrointestinal tract, thyroid and blood. Patients with tuberculosis, leukemia, hypertension, malaria and many of the infectious diseases such as measles, whooping cough, typhus, tularemia, spirochetal jaundice (Weil's disease), smallpox and typhoid were also seen. Several patients with traumatic injuries were included. In a large number of patients the authors found many arterioles both temporarily and permanently plugged with masses of sludge, represented by agglutinated masses of red blood cells (not rouleaux). Other observers (Odell, Aragon and Pottinger) examined the circulating blood of 31 women with normal, uncomplicated pregnancies and found sludged blood in 12. Of 23 women with various pathologic complications of pregnancy, 22 showed sludged blood.

Not only were agglutinated clumps of red blood cells found in all severely sick persons, but all types of pathologic tissues were seen. Both red and white blood cells were observed sticking to the linings of small vessels. Circulating masses of agglutinated white and red cells were seen to enter and plug small arterioles, which subsequently dilated, bulged, sacculated and leaked fluid into surrounding tissues. Patients in whom the sludging of blood was advanced manifested evident slowing of the circulation, as judged by circulation through the arterioles observed. This occurred in several instances in spite of hypertension. Every severely ill person who was observed had intravascular agglutinated blood and visible pathologic change of the vessel walls.

¹ Knisely, M. H.; Bloch, E. H.; Eliot, T. S., and Warner, Louise: Sludged Blood, *Science* 106:431-440 (Nov. 7) 1947.

In attempting to determine how sludged blood damages the body the authors concluded that: (1) the resistance of sludged blood to its own passage through the bottlenecks of the circulatory system forcibly reduces rates of flow through all the open vessels of the body; (2) agglutinated red cells are ingested and destroyed in the phagocytic cells of the liver and spleen; (3) there is a stalling and sedimenting of the masses of blood cells out of the plasma during life, and (4) various degrees of reduction of circulating blood volume caused by factors (1) and (2) initiate intermittent, prolonged shutting off of the arterioles of selected tissues and organs.

The authors expressed the belief that their observations have clarified many fundamental ideas about disease and have made simpler the solution of certain groups of currently perplexing problems. If it can now be learned how to keep blood fluid and unagglutinated and vessel walls intact with adequate blood volume present, many effects of other pathologic mechanisms can be more clearly determined, unobscured by disease effects resulting from the sludging mechanism.

As a result of publication of this report, many practicing physicians have suggested use of heparin or "dicumarol" to prevent the sludging of blood in patients met in their daily practices. Until these observations have been extensively checked by other investigators, introduction of new methods of treatment to combat sludging of blood should be highly experimental.

THE CONTRIBUTION OF A MEDICAL SCHOOL TO THE HEALTH PROGRAM OF A COMMUNITY

A medical school can make important contributions to the health program of the community in which it is located. The booklet "Bringing Modern Medicine to the People,"¹ outlines the long range program developed by the Long Island College of Medicine for serving better the nearly five million persons who live in Brooklyn and Long Island.

Medical schools are no longer merely centers for undergraduate instruction more or less isolated from their communities. American medical schools are making increasing contact with all phases of medical care. The community looks to its medical schools for leadership in formulating and directing better forms of medical service. Medical schools are accepting this challenge and, within the capacity of their resources, are seeking to place their personnel and facilities at the service of the people of the area in which they are located. In the plan advanced by the Long Island College of Medicine, special emphasis is placed on the promotion of community health through coordination

of the medical school's program with the activities of the other health resources in the Brooklyn-Long Island region. At the hub of the network of facilities for medical education, research and medical care and the community health program planned by the medical school will be the Long Island College of Medicine-Brooklyn Medical Center, comprising the projected new medical school plant, a university hospital and health center and the adjacent city hospitals and related laboratory units.

Today the medical school is an acceptable agency for integration of the medical and health resources in a communitywide cooperative program for the better health of more persons. In achieving this objective the medical schools of this country will require greatly increased financial support. The Long Island College of Medicine has estimated that it must secure \$7,000,000 by 1950 and an additional \$9,000,000 by 1960 to carry out its program. In terms of the benefits that will accrue to the community the amounts are small. The program contemplated, especially when integrated with voluntary prepaid insurance plans, will go much further in providing adequate medical care of high quality than will any alternative scheme thus far proposed, and at much less cost.

THE NEED FOR PLASMA SUBSTITUTES

Since adequate amounts of pooled human plasma were readily available for the treatment of traumatic shock during World War II, research in the development of suitable substitutes was not extensive. Plasma was employed on a large scale; at first hazards were not anticipated with its parenteral administration in contrast to those associated with the various substitutes, such as acacia, pectin, polyvinyl alcohol, methyl cellulose, gelatin and cattle plasma. However, the mounting evidence that infectious hepatitis is transmitted not infrequently by pooled plasma definitely contraindicates any indiscriminate therapeutic use of this agent. The relatively high cost of human plasma, moreover, is a deterrent when large amounts are required for diuretic purposes in the treatment of nephrosis.

Colloidal plasma substitutes have retained a limited position in the medical armamentarium despite the objectionable properties which they display, especially when injected repeatedly in large amounts.¹ The recent report of Mannix² on a fatal case of nephrosis complicated by arabinosis, which was produced by the repeated administration of large amounts of acacia, presents a striking illustration of the dangers connected with the use of such agents. Subsequent to initial satisfactory diuretic responses to acacia, hypersensitivity; loss of erythrocytes, hemoglobin and plasma

proteins; acceleration of erythrocytic sedimentation; absence of a diuretic reaction; evidence of hepatic injury, and hepatomegaly appeared. These symptoms, resulting from the progressive storage and retention of gum acacia in the tissues. These symptoms, reflected in part impaired function of internal organs. At autopsy the liver, spleen and kidney were three to five times normal weight and showed large amounts of acacia in swollen reticuloendothelial cells and histiocytes, which were transformed thereby into foam cells. Similar cells were present in the marrow, lymph nodes, thymus and adrenals, and in atheromatous patches of the aorta. In this case the retention of acacia quite certainly contributed to the fatal outcome.

The contrasting results reported by other investigators in different patients of similar ages, who received acacia in comparable amounts, may be attributable in part to the possible absence of toxic impurities in the preparations that they used. In part the differences may result from variations in the molecular size of the acacia, which is apt to vary with the source and treatment of the gum.

The case is a vivid illustration of the need for an effective, stable, cheap and readily available substitute for human plasma free from the objectionable features of both pooled human plasma and substitutes now in use.

Current Comment

A NEW LOW IN PROMOTION OF TESTOSTERONE

Writers of promotional material constantly seek new and novel means to extend the sales of the products they extol. A new low seems to have been reached in the promotion of a brand of testosterone. A brochure entitled "Male Sex Hormone Therapy in the Male and Female" lifts a partial quotation from an article by Thompson,¹ "failure to show improvement means that the symptoms complained of are not the result of the male climacteric," to suggest that testosterone be administered as a means of diagnosis. If the patient improves following male hormone therapy, he is in the midst of his climacteric—the testosterone goes in and the diagnosis comes out—either he has it, or he hasn't. The fallacy should be obvious. Too often uncritical readers swallow such *post hoc ergo propter hoc* reasoning without appreciating its absurdity. Vague symptoms of anxiety, tiredness and inertia respond often to the administration of a placebo or even to simple suggestion. If an injection of distilled water results in temporary alleviation of such symptoms, shall we conclude that lack of water caused them? Evidently our medical schools must put more stress on scientific judgment and evaluation of evidence.

STILLBIRTHS

In 1934 the number of stillbirths in the United States was 78,503;¹ the number of stillbirths at present² is about 65,500 a year. It appears that the chances of being born alive are best for the second child and decrease progressively for each successive child. The stillbirth ratio among second children in this country, exclusive of Massachusetts, for the period 1940 to 1944 was 18.5 per thousand live births, while the ratio for the first born was 24.4, or about one third greater. Births of the seventh order were twice as likely to be stillborn as were those of the second order, while for the tenth and later born the ratio was three times as great. A second and more important factor in stillbirths, the *Statistical Bulletin of the Metropolitan Life Insurance Company* says, is the age of the mother. The tendency of the stillbirth ratio is to rise with the increasing age of the mother. A child is more likely to be born alive when the mother is in the age group 20 to 24 years. The ratio at ages 30 to 34 is more than 50 per cent greater, more than twice as great at ages 35 to 39, three times as great at ages 40 to 44 and at least four times as great at 45 and over. The stillbirth ratio is relatively high also among mothers who bear a large number of children in rapid succession. Mothers under 20 years of age who bear their fourth child show a considerably higher stillbirth ratio than do mothers in every other age group up to 40 years; the same is true for women who bear their sixth child as early as 20 to 24 years. While the reduction already achieved in the number of stillbirths is a source of satisfaction, much remains to be accomplished in this field of conserving life. The hazard of stillbirth could be further reduced if more mothers received medical care early in their pregnancy; this is particularly important for pregnant women at both extremes of the childbearing period.

CASEIN AND LACTALBUMIN

Osborne and Mendel in their extensive investigations of proteins and amino acids observed that lactalbumin is superior to casein in nutritive value. This conclusion was reached following careful quantitative feeding experiments with albino rats.¹ The increasing use of protein hydrolysates in parenteral feeding in medicine makes important a comparison between these widely used proteins in human nutrition, as casein will probably always be more readily available than lactalbumin. Mueller and Cox² have compared the influence of these two proteins on the nitrogen balance in human subjects under experimental conditions which permitted the calculation of biologic values as well. They concluded that there is little, if any, difference between the nutritive values of casein and lactalbumin under the conditions of their study.

ORGANIZATION SECTION

THE SAN FRANCISCO MUNICIPAL EMPLOYEES' HEALTH SERVICE SYSTEM

INTRODUCTION

ROBERTSON WARD, M.D.

President, San Francisco County Medical Society

In view of the existing controversy between the proponents and opponents of compulsory health insurance, I believe that a historical review of the situation in San Francisco would be of interest to the readers of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

In my opinion this situation is of more than local interest; in fact, it is fundamental to American medicine.

Like most compulsory systems, the San Francisco Municipal Employees' Health Service System started out by promising too much for too little—in an attempt to stifle opposition to its compulsory payroll deduction features. And like most systems of socialized medicine, when financial difficulties developed it first siphoned off funds needed for medical services to help defray the costs of bureaucratic overhead. When that failed to balance the books, the system increased its rates to insured members—and then took the final step, characteristic of all experiments in socialized medicine, by demanding that physicians lower the quality of medical and hospital care provided their patients.

The San Francisco Municipal Employees' Health Service System has provided a perfect example of socialized medicine for a ten year period—bureaucratic interference with doctors and their patients, dictating to physicians how they shall treat their patients, attempting to foist second class medicine on doctors and patients, domination of laymen in the management—and all the other evils with which medicine is threatened nationally, and which actually happened here in San Francisco!

ADDRESS

ANTHONY B. DIEPENBROCK, M.D.

Retiring President, San Francisco County Medical Society

The fundamental and the fatal deficiency in the set-up of the San Francisco Municipal Employees' Health Service System, and the one which physicians have finally been compelled to reject unequivocally, is that it is a compulsory system, which city employees are forced to join as a condition of their employment.

Its operation as a laboratory experiment in socialized medicine has confirmed that when compulsion is employed to bring physician and patient together, the quality of medicine deteriorates and patient and doctor alike become pawns in the hands of bureaucrats.

It confirms, too, that government-dominated medicine is bad medicine. In the case of the health service system, however, members of the medical profession do not rest their opposition to its continuation as a compulsory system on abstract or ideological theories. Certainly, opposition to socialization of the medical profession is included among the most important objections, but in the case of the health service system a realistic appraisal of its function proves that city employees can only expect treatment as second class patients and that they will continue to be deprived of medical and surgical services for which they are paying, but which the system denies them.

How, it may be asked, did this health service incubus fasten itself on the medical profession and the city of San Francisco? Let me review its history. The San Francisco Health Service System, the only compulsory system of health insurance for municipal employees in the United States, came into being as the result of a charter amendment passed by the electorate on

March 9, 1937 by a vote of 76,749 to 56,615. Physicians had grave misgivings about the experiment then, but they decided to go along with the plan in view of the people's endorsement of the charter amendment. Soon the misgivings held by members of the medical profession about the plan received confirmation from actions taken by the system's board of directors, and in 1939 the medical society voiced its public criticism of the operations of the health service.

The society called attention to the fact that the medical director of the system was arbitrarily refusing patients certain services to which they were obviously entitled. Permission for hospitalization for necessary surgical or medical treatment was extremely difficult to obtain even in some cases of acute illness. Fee schedules for operations were disregarded, even though the doctor was then receiving only 50 cents on the dollar for his services.

The physicians, in truth, carried the system along by their willingness to accept whatever was available to reimburse them for their services in the month to month operations of the health service. It is only fair to point out here that fee schedules are not and never have been the source of the medical profession's objection to the system's procedures but that in all cases, from the very beginning of its operation, the forgotten man or woman—the patient—has been and continues to be the doctor's chief concern with the functions of the health service.

Suffice to say on the subject of fee schedules that an actuarial study of the system, completed early in 1942 by an independent analyst, Mr. Ralph R. Nelson, revealed that if agreed fee schedules had been paid to physicians since the start of the system, an additional \$400,000 would have been received by the professional staff members. It cannot be denied that this \$400,000 contribution by the members of the medical profession was the only thing that kept the system afloat.

The preoccupation of San Francisco physicians during the war forced them to overlook the interference of the medical director and the board of directors of the system in the treatment of patients and the undermining of professional ethics incidental to the practice of medicine under a compulsory system.

But the kettle continued to simmer until May of this year, when the lid blew off. The system's board, through its medical director, sent to those who were members of the professional staff a letter advising them to conform to certain procedures, conformity with which would place physicians in the position of betraying their oath and endangering not only the health but the very lives of their patients.

That letter, written by the medical director, was dated May 28, 1947. It was an astonishing document. Because the health service system was again in financial difficulties, physicians were bluntly advised to lower the quality of medical care provided the 17,000 city employees by limiting laboratory tests, by curtailing roentgenologic examinations and by disregarding normal diagnostic procedures.

These instructions from the medical director and the board, as I have stated, were based on the premise that they were necessary because the system was losing money, even though it had only a short time before increased its rates to its employed members by 21.5 per cent and dropped the unit value paid to doctors, by 20 per cent.

Only by economizing at the expense of their patients, physicians were flatly told, could they expect to have their fees returned to the former level or escape future reductions.

In effect the letter not only confessed that the system was actuarially unsound and could not keep its commitments to the 17,000 persons contributing to it, but it stated almost in so many

words that the members of the medical profession in San Francisco would have to cheapen the quality of medical care and deny city employees the high standard of care which was provided for private patients.

The physicians of San Francisco refused to gamble with the health of their patients to improve their own fee schedule and they will continue to reject that gamble, just as they are refusing and will continue to refuse to be parties to the continuation of a political experiment in cheap assembly line medicine.

Specifically, the system's directive told the members of the medical profession to substitute "routine examinations" for diagnostic procedures which any doctor who is worthy of his degree considers essential for the early detection of cancer, tuberculosis, pneumonia and other diseases.

The directive further advised physicians to discourage patients with "minor ailments" from seeking medical treatment, and to advise these patients to use "home remedies."

More than this, physicians were instructed that the health service system would permit hospitalization, except in emergency cases, only with specific authorization by the medical director of the system.

The hundreds of resignations which followed that directive—a directive that has never been recalled, amended or modified in any way—were submitted in protest against a type of questionable practice and unethical procedure which the directors of the health service countenanced for the sake of bolstering a medically and actuarially bankrupt system.

Consider this paragraph from the letter sent to San Francisco physicians serving the system by the medical director, with the consent of the board of directors:

"People in general have more knowledge now on medical subjects, gained from magazines, public lectures and from over the radio; also from quack advertisements in the newspapers. Much of the so-called medical knowledge gained in this way has given them a mass of false information. It has brought about many unnecessary visits to the doctor to get treatment for trivial things—such minor ailments as could be treated, as well, by their home remedies as by the doctors. Such needless calls take up the doctor's time and add a great expense for the System."

This truly amazing observation is of a pattern that would turn back the clock in medicine a hundred years if it became the medical profession's guide in considering whether or not a patient deserved treatment.

The same letter, as I have already noted, asked physicians to limit and restrict the use of laboratory tests, roentgenologic examinations and normal diagnostic procedures, to substitute routine examinations for scientific diagnosis and to discourage patients with minor ailments from seeking medical treatment and advise them to use home remedies!

In effect, a patient with a sore lip presumably would be encouraged to go to the corner drug store, buy some salve and daub it on himself, rather than to consult an ethical physician who could determine whether the lesion was a cold sore or a cancer of the lip.

I wonder whether any member of the medical profession, when his wife or child was ill, would want them to have that kind of routine examination?

I do not want to quote unnecessarily from the health service medical director's letter, but the simple truth is that it confirms in black and white the very point that I made in the opening portion of my article—that state medicine, socialized medicine, bureaucratic medicine or medicine by any similar name or term is bad medicine and can only lead to the vicious consequences that this letter makes it plain have resulted from the ten year operation of the San Francisco Municipal Employee's Health Service System.

To return briefly to that letter, the observation was made in it that the system's medical director believed that: "between 50 and 60 per cent" of the roentgenologic examinations he inspected were unnecessary. When that statement is turned around, apparently 40 to 50 per cent of the roentgenologic examinations were necessary! What type of medical practice would physicians have if they failed, due to false economy, to make proper diagnosis in 50 per cent of cases, or even in 25 per cent? Is that the kind of health service the city employees are

entitled to and to which a system of compulsion makes it necessary for them to contribute a part of their salary each month? Is that type of medical care defensible from any point of view? The physicians of San Francisco believe that it is not. No self respecting doctor, with pride in his profession, will be a party to any program to treat city employees as second class patients, to enable any system to survive which has proved itself a hopeless experiment basically, medically and actuarially.

Now, what does the record show as to the physicians' willingness to cooperate with the system in trying, despite the crippling disadvantages of compulsion and socialization, to make the system work? Physicians have contributed approximately a half million dollars in fees to which they were entitled under the very moderate fee schedule set up in the system. They have pointed out time and again through the years the right of the patients to full medical and surgical, hospital and office treatment. They have patiently sought to induce the system's medical director and board to institute procedures and practices conforming to the finest medical standards. But through the years the record will show that attempts to work with the board of the health service have been met by an arrogant refusal even to consider objections and recommendations.

Take the record leading to the present impasse. The director's letter to which I have referred was written May 28, 1947. On June 18 the society voiced a vigorous protest to the board, stating that if the health service system could not provide adequate care for its insured members it should in all fairness so advise the city employees—and not ask doctors to go against their own medical judgment when the health and possibly the lives of patients might depend on the decision.

The letter concluded: "We believe that your board, rather than attempting to bolster an unsound system by the wholly impractical and medically dangerous expedients set forth in your letter of May 28, should frankly tell the city employees that the present plan has failed.

"We believe that you should then state that you wish an expression of opinion from them as to whether an insurance-indemnity system should be established, or whether a contract should be entered into with one or several of the established voluntary systems to provide the necessary coverage." Both alternatives are permitted by the City Charter.

What was the response of the board to this communication of the society? The board met on June 24, 1947 and, according to the official minutes of that meeting, moved that the letter of the society be "filed without prejudice."

The society waited patiently for an answer for more than three and one-half months, despite the fact that the system's board was morally as well as legally bound to reply. Section 172.1 of the City Charter provides:

The Health Service Board shall receive, consider and within sixty (60) days after receipt, act upon any matter pertaining to the administration, operation or conduct of the Health Service System submitted to it in writing by any member of the system or any person who has contracted to render medical care to the members of the system.

Meantime, the medical society waited—not sixty days, but one hundred and ten days! It was never given the courtesy of a reply.

During this period the smouldering resentment against the system was bursting into flame among the physicians. A spontaneous movement to resign developed and spread like the proverbial wildfire.

I want to emphasize that this started from the bottom and flared up—not from the top down, as has been implied. The officers and directors of this society, had they been so inclined, no more could have dampened this movement than can the executives of any democratic organization thwart the wishes of the majority.

On October 8 the board of directors of the San Francisco County Medical Society dispatched another communication to the health service system's board. That letter stated that the resignations of more than eight hundred physicians would be presented on Nov. 10, 1947 unless the system was reorganized on a sound medical basis acceptable to the society and the physicians who serve the system.

The letter also stated that if a committee representing the board of the health service system wished to discuss the problem, the county medical society would be glad to cooperate.

Confronted with the resignations, the board of the system took notice of the October letter, rather than filing it along with the June letter, and condescended to talk it over. It took more than a week to get around to naming the committee, and then two of the key members were too busy to meet with representatives of the physicians.

The meeting was held Friday, October 24, and accomplished exactly nothing. The system's representatives used the occasion for indulging in personalities, which had no relation to the issues in question. They did, however, reluctantly agree to present the society's demands to the entire membership of the board.

On October 29 the board replied that it was unable to meet the society's recommendation for revision of the system. The board fell back on an opinion of the city attorney as an excuse for its failure to act. This opinion did not tie the board's hands. There were well defined remedies available, had the board wanted to find a remedy.

Physicians believe that the city employees of San Francisco and their dependents should be given the same freedom of choice to select the type of medical and hospital care that is given employees of the state of California and the city of Los Angeles.

There is nothing compulsory about either the state employees' system or the Los Angeles city employees' health system. Under these systems, the employee can elect: (1) to make provision for his medical care with his own physician; (2) to join a voluntary health insurance system with indemnity cash payments to help defray his medical and hospital bills, or (3) to enroll as a member of a voluntary medical and hospital service plan which will provide him with health care in time of illness.

After it became apparent that no sincere attempt was being made by the board to reorganize the system on a sound foundation or to adopt the alternative proposals suggested by the Medical Society, the board was notified on November 5 that it was clearly apparent no basis for further discussions existed.

The physicians' resignations were filed on November 10, and at present, according to records of the medical society, less than one hundred physicians of a San Francisco staff numbering nearly one thousand remain on the panel of the health service system.

I want to make it clear at this time that the doctors of San Francisco are not urging the selection of any particular voluntary health insurance system or medical care system. They believe that city employees should be given the right to choose between several systems—and there are over a hundred sound voluntary health insurance systems and indemnification plans operating in California today—and to select the one that best suits their needs.

The physicians of San Francisco do insist on one cardinal point, that the compulsory features of the present system must be eliminated so that third party interference between the physician and his patient can be eliminated.

The San Francisco City Charter, which created the health service system, provides two alternatives to the present compulsory system: It authorizes an insurance-indemnity plan under which beneficiaries of the system would be entitled to cash benefits to pay their medical and hospital bills. Alternatively again, it authorizes a contract with any one or several of the established voluntary health and hospital insurance systems to provide the insured beneficiaries with adequate care.

Either of these alternatives to the present system would be acceptable to the members of the medical profession, provided that membership in either plan is not compulsory. To eliminate the compulsory aspect of the system, the City Charter would have to be amended. The physicians of San Francisco are willing to support the system's board of directors in a request by them to the board of supervisors for the submission of an amendment eliminating this compulsory phase of the health service. Such amendment could be submitted to the voters in the primary next year, and the physicians would support a campaign for its acceptance by the voters.

Unless the system's board is willing to proceed in the manner that I have outlined, the physicians of San Francisco will continue to dissociate themselves from any function of the system, although—and this hardly need be repeated—they will continue to serve members of the system as private patients.

In this connection I would like to quote from the society's letter of October 8 to the system's board, which said: "Regardless of the course of action you may decide upon, we wish to assure you that there will be no interruption in the medical care provided the city employees and that doctors will continue to treat them, but as private patients, if your board fails to provide an acceptable alternative program. For your information, members of the County Medical Society maintain a physician-patient service agency known as the Bureau of Medical Economics, and that Bureau will guarantee to arrange for the finest standard of medical care in any distressed cases among city employees, regardless of ability to pay."

In conclusion, may I be permitted the observation that the medical profession is convinced that its continued refusal to submit to socialization and to arrogant bureaucratic control of its professional functions is a position that may well be applauded by any person, professional or otherwise, who believes that the American system of free enterprise is worth saving.

Washington Letter

(From a Special Correspondent)

Feb. 19, 1948.

President Urges Public Support in Combating Heart Disease

Calling for observance of National Heart Week, sponsored by the American Heart Association, President Truman asked every citizen of the United States to cooperate with his physician and his community in guarding against heart disease. Mr. Truman said, in part: "I have seen reports stating that diseases of the heart and blood vessels constitute the most frequent cause of death. One out of every three deaths in the United States is caused by them; indeed, deaths from cardiovascular disease are greater than the total resulting from the next five leading causes combined. Heart disease is also a major cause of disability. . . . The medical profession alone cannot succeed in fighting this menace without the fullest cooperation from the general public. . . . The duty of each American is to cooperate with his physician in protecting his health and that of his family and to cooperate with his neighbor in supporting community efforts directed against this enemy of the people."

Forrestal Asks Reexamination of Military Men Retired for Disability

Criticism of army disability retirements has resulted in a request to Congress by Defense Secretary Forrestal that medical reexaminations be provided for every military man retired for physical disability since 1939. Mr. Forrestal proposed that officers and enlisted men retired since that year should not be eligible to receive their pensions unless they submit to reexamination. He recommended: (1) that every person retired for physical disability since 1939 be reexamined and receive periodic reexaminations; (2) that benefits for physical disability be related to the percentage of actual incapacity for duty, which applies only to enlisted men at present; (3) that physical disability benefits be applied equally to all the armed services, both regular and reserve, officers and enlisted men, and (4) that tax exemption, if it is to apply at all, be applicable only to payments representing benefits for actual physical disability.

New Army Chief May Seek Aid of Civilian Doctors

In event of passage of universal military training, the new Army chief of staff, General Omar Bradley, successor to Gen. Dwight D. Eisenhower, is expected to follow tactics similar to those he used so successfully in improving medical service for veterans as veterans administrator. It is pointed out here that through Major Gen. Paul Hawley, who served under him as veterans' medical chief, General Bradley obtained cooperation of the deans of the seventy-seven class A American medical schools in setting up a teaching program for young resident physicians in veterans' hospitals. This work on the medical reorganization of the agency gave General Bradley contact with leading civilian educators, particularly in the medical field, and it is believed likely that he would again ask their support if required to organize the Army training program.

Medical Legislation

STATE LEGISLATION

Kentucky

Bills Introduced.—H. 168, to amend the premarital examination law, proposes to require each applicant to be examined by a physician authorized to practice in Kentucky as to the existence or nonexistence of any stage of syphilis infection that is or is likely to become communicable. S. 96 proposes the creation of a state hospital board and a hospital advisory council. The state hospital board would be required to make an inventory of existing hospitals and to develop and administer a plan for the construction of needed additional facilities. The state hospital board would further be authorized to make applications to the Surgeon General for federal funds to assist the state in carrying out its inventory and construction program. S. 135 proposes the creation of a board of examiners for the certification of clinical psychologists. S. 137 proposes the enactment of a licensing law for chiropractic hospitals to be administered by the Kentucky state board of chiropractic examiners. The proposal would also authorize the state board of chiropractic examiners to accept, on behalf of the chiropractic profession and their patients in the state of Kentucky, any funds or grants through appropriate channels and any supplies and equipment which may be made available to the state for hospital facilities, goods and services.

Massachusetts

Bill Introduced.—H. 1467 proposes regulations concerning the performing on any animal of any pain-producing experiment. Licenses to perform such experiments would be issued by the commissioner of public safety and would be for three years' duration.

Bill Enacted.—H. 91 has become chapter 28 of the Laws of 1948. It amends the medical practice act by providing for the revocation of the certificate of registration of any physician guilty of the use of narcotic drugs in any way other than for therapeutic purposes.

Mississippi

Bills Introduced.—H. 290 proposes to authorize the establishment of a scholarship program for the advanced study of nursing, which would list of forty scholarships of the value of not more than \$3,000 each. S. 291 proposes to accept assistance from these scholarships must agree to a period of time working as nurses in Mississippi equal to the number of years during which they accepted the benefits of the scholarships. H. 291 proposes to authorize the establishment of a school of nursing at the University of Mississippi and to inaugurate a scholarship program in connection therewith. S. 145 proposes the creation of a board of examiners in optometry and, among other things, proposes to declare the practice of optometry to be a profession. S. 159 proposes the enactment of a workmen's compensation law.

Bill Passed.—S. 68 passed the senate January 23. It proposes that the board of trustees of universities and colleges shall maintain the first two years of the four year medical school at Oxford, Miss., until such time as the legislature shall authorize the removal therefrom, and the remainder of the medical course to be located in conjunction with a standardized and departmentalized hospital for teaching purposes of not less than three hundred and fifty beds.

New Jersey

Bill Introduced.—A. J. Res. 2 proposes the creation of a commission of five members to make a survey of all voluntary charitable hospitals throughout the state to determine what steps can be taken to relieve existing overcrowding and to furnish additional revenue for operating costs to relieve the burden now being carried by the voluntary charitable hospitals.

New York

Bills Introduced.—A. 634 proposes the creation of a temporary state commission to make a study and survey of the prevalence and facilities for the treatment of infantile paralysis patients within the state. A. 931 proposes the enactment of a New York state health service act. According to this proposal it is the intent to encourage and assist the development of voluntary prepaid health and hospital plans and to eliminate from its provisions persons protected under voluntary plans provided such plans furnish the medical and hospital benefits established by this proposal. A. 970, A. 1194, S. 994 and S. 1072, to amend the education law relating to the practice of nursing, propose to authorize the department to license without examination graduates of accredited nursing schools from some other state who have completed a course of study considered by the department to be equivalent to that required in the state of New York and who have met all the requirements as to age, character, citizenship and preliminary education. A. 990, to amend the education law, proposes to make it the duty of each medical inspector having jurisdiction over any public school in the state to examine each pupil attending such school for symptoms of tuberculosis at least once in each school year. A. 1199 and S. 1170, to amend the workmen's compensation law, propose to include within the coverage thereof assistant resident interns or resident interns or resident physicians in certain state hospitals. A. 1558 proposes an appropriation of \$2,500,000 to the department of health to defray the cost of research in the cause and cure of cancer. A. 1586, to amend the public health law, proposes to require all hospitals or similar establishments to provide complete physical examinations annually to all employees, which physical examinations shall serve to determine the presence or absence of any communicable disease. S. 1069, to amend the education law, proposes the creation of a board of examiners of psychologists for the certification and registration of professional psychologists. S. 1182, to amend the labor law, proposes to regulate the hours of employment of registered professional nurses to not more than five days or forty hours a week

except in case of emergency and not more than eight hours in any day except in case of emergency. S. 1189 proposes the creation of a temporary commission to make a study and analysis of the advisability of grants-in-aid to cities, counties and other state subdivisions for the purpose of developing and expanding non state-operated clinics and other psychiatric facilities for the care and treatment of the mentally ill and potentially mentally ill. S. 1248, to amend the education law, proposes that x-ray diagnosis means that method of medical practice in which demonstration and examination of the normal and abnormal structures, parts or functions of the human body are made by the use of x-rays, and any person who holds himself out to diagnose or able to make or makes any interpretation or explanation by word of mouth, writing or otherwise of the meaning of a fluoroscopic or registered shadow or shadows of any part of the human body made by the use of x-rays, and also the use of x-rays or radium for the treatment of any human ailment, shall be deemed to be engaged in the practice of medicine within the meaning of the medical practice act. S. 1383, to amend the penal law, proposes that any person who either treats or offers or undertakes to treat the human body without first having complied with the appropriate statutes of the education law is guilty of a misdemeanor. S. 1422, to amend the education law, proposes that any person studying to become a registered nurse who has resided in the state of New York for two years prior to attending a school of nursing registered by the department shall receive from the department \$50 for each such month of attendance during the first and second year of attendance and \$75 for each such month of attendance during the third year of attendance.

Coming Medical Meetings

- Alabama, Medical Association of the State of, Mobile, April 15-17. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.
- American Association of Industrial Physicians and Surgeons, Boston, March 28-April 4. Dr. Frederick W. Slob, 28 E. Jackson Blvd., Chicago 4, Secretary.
- American Broncho-Esophagological Association, Atlantic City, Chalfonte-Haddon Hall, April 7-8. Dr. Paul H. Holinger, 700 N. Michigan Ave., Chicago 11, Secretary.
- American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.
- American Laryngological, Rhinological and Otolological Society, Atlantic City, April 7-9. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.
- American Orthopsychiatric Association, New York, Hotel Commodore, April 12-14. Nina Ridenour, Ph.D., 1790 Broadway, Rm. 916, New York 19, Secretary.
- American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Philadelphia, Feb. 26. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.
- American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.
- Arkansas Medical Society, Little Rock, Robinson Auditorium, April 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.
- California Medical Association, San Francisco, April 11-14. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.
- Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.
- Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.
- Florida Medical Association, St. Augustine, Ponce de Leon Hotel, April 11-14. Dr. Robert B. McIver, 111 W. Adams St., Jacksonville, Secretary.
- Louisiana State Medical Society, Monroe, April 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.
- Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.
- Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.
- New England Dermatological Society, Boston, April 14. Dr. G. Marshall Crawford, 1180 Beacon St., Brookline, Mass., Secretary.
- New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, Feb. 23-26. Dr. Max M. Green, 1430 Tulane Ave., Room 105, New Orleans 13, Secretary.
- Northern Tri-State Medical Association, Findlay, Ohio, April 13. Dr. Don F. Cameron, 247 W. Berry St., Ft. Wayne, Ind., Secretary.
- Pacific Coast Surgical Association, Los Angeles, Ambassador Hotel, Feb. 24-28. Dr. Carleton Mathewson Jr., Stanford Univ. Hospital, San Francisco, Secretary.
- Southeastern Surgical Congress, Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S. E., Atlanta 3, Ga., Secretary.
- Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.
- Tennessee State Medical Association, Nashville, April 13-14. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.
- United States-Mexico Border Public Health Association, Laredo, Texas and Nueva Laredo, Mexico, March 20-22. Dr. M. F. Haralson, U. S. Court House, El Paso, Texas, Secretary.

GOVERNMENT SERVICES

NAVY

DISEASE IN THE NAVY DURING WORLD WAR II

In an address before the Harvard School of Public Health, Boston, February 7, Rear Admiral C. A. Swanson, Surgeon General of the United States Navy, said that no devastating epidemics swept the service during the recent war and that the reduction in the noncombat death rate, as compared with World War I, effected a saving of more lives than the total number lost through enemy action. During the war the average strength of the Navy for the four years was in the neighborhood of two and one-half millions. There were only 8 cases of smallpox, 96 of typhoid and 4 of tetanus, with two deaths in persons whose records indicated that their immunization had been incomplete. Tetanus did not develop in any combat casualty. Six hundred and fifteen cases of the rickettsial group of diseases were reported, the majority being tsutsugamushi fever in the Southwest Pacific campaigns. There were no cases of cholera, plague or yellow fever.

ACTIVATE RESERVE MEDICAL DIVISIONS

The headquarters of the Third Naval District in New York has announced that in conformance with directives from the Bureau of Naval Personnel, forty-two Volunteer Medical Reserve Divisions were activated January 15, and that four more divisions are being organized. Each division will have the following personnel: seventy-five medical corps; fifteen medical service corps; fifty nurse corps officers, and two hundred and fifty hospital corpsmen. These divisions have been set up for training purposes, but in case of national emergency the personnel may be ordered to active duty individually or as units.

NARRATIVE OF MEDICAL WORK IN WORLD WAR I

The Bureau of Medicine and Surgery has published for the first time an official historical narrative pertaining to its Medical Department in the first World War. The book entitled "The Medical Department of the U. S. Navy with the Army and Marine Corps in France in World War I" was written by Lieut. George G. Strott (HC), U. S. Navy (retired), who spent some thirty years in collecting material for this book. Lieutenant Strott was a chief pharmacist's mate in France and served

with the Sixth Marines until the end of the war. This story deals with the activities of the 2d Division, American Expeditionary Forces, and of the only major unit of the Navy Medical Department to serve as a component of an Army combat division. The three hundred and twenty-two page volume may be purchased for 75 cents from the Superintendent of Documents, Government Printing Office, Washington, D. C.

PENSACOLA NEWS

At the invitation of Rear Admiral Frank D. Wagner, chief of Naval Air Training, the National Research Council's Committee on Aviation Psychology met at the Naval Air Station, Pensacola, Fla., January 30-31. Capt. Marcio Baeza, chief surgeon of the Chilean air force reserve and professor of surgery at the University of Chile in Santiago, was present at the meeting. Captain Baeza inspected the Naval School of Aviation Medicine and Research, the Naval Hospital and the other medical air facilities at Pensacola. After the meeting the members were guests of the local command aboard the aircraft carrier, U. S. S. *Wright*.

GRADUATE TRAINING

The Bureau of Medicine and Surgery, Washington, D. C., as of February 4, in continuing its graduate policy for medical officers, announced approval of some twenty-six assignments of officers to pursue graduate courses and residencies in various hospitals and universities throughout the country.

PERSONALS

Two new members have been appointed to the Board of Civilian Consultants to the Bureau of Medicine and Surgery, Washington, D. C.: Dr. Lowell T. Coggeshall, dean, division of biological sciences, University of Chicago, as consultant in tropical medicine, and Dr. Donald Anderson of Chicago, secretary, Council on Medical Education and Hospitals of the American Medical Association, as consultant in hospital administration.

Rear Adm. Clifford A. Swanson, Surgeon General and chief of the Bureau of Medicine and Surgery, addressed the Saturday Morning Health Forum of Harvard University School of Public Health at Boston, February 7, on "The Health Program of the United States Navy."

PUBLIC HEALTH SERVICE

DR. SCHEELE TO SUCCEED DR. PARRAN AS SURGEON GENERAL

The White House has announced the nomination of Dr. Leonard A. Scheele as Surgeon General of the U. S. Public Health Service, to succeed Dr. Thomas Parran when the latter's term expires April 6, 1948.

Dr. Scheele was born in Indiana, received his A.B. degree from the University of Michigan and his M.D. from Wayne University, Detroit. He was commissioned in the Public Health Service in 1934, was first assigned as assistant quarantine officer at the Port of San Francisco, then at the Port of Honolulu; he was health officer of Queen Anne's County, Maryland, in 1936-1937. He was officer in charge of the National Cancer Control Program of the National Cancer Institute from 1939 to 1942 and chief, field casualty section, Medical Division, Office of Civilian Defense, in 1942 and 1943. He was assigned to the Army from 1943 to 1945, serving in Military Government and Allied Commission medical operations in Sicily and later as officer in charge of the preventive medicine section at Supreme Headquarters of the Allied Expeditionary Force in Northwest Europe. He was medical representative of the medical section of the Allied Control Council in initial operations of that group in Berlin after the surrender of Germany.

Dr. Scheele was awarded the American Typhus Commission Medal for work in the control of typhus in Northwest Europe during 1944-1945, the Legion of Merit for his communicable disease control work in the European theater and the Order of Public Health from France.

From 1946 to 1947, he was assistant chief of the National Cancer Institute of the National Institute of Health and in July 1947 he became assistant surgeon general of the U. S. Public Health Service and director of the National Cancer Institute.

Dr. Parran was appointed Surgeon General in April 1936 and reappointed in 1940 and 1944. He has been a commissioned officer in the Public Health Service since 1917. Previous to his assignment as Surgeon General, he had served in fourteen states on public health research and administrative assignments and from 1930 to 1936 as commissioner of health for the state of New York. In a statement Dr. Parran said, among other things, that "the President is to be congratulated on his appointment of Dr. Leonard A. Scheele as Surgeon General of the U. S. Public Health Service. . . . I have no plans for the future. I shall be at the disposal of my commander in chief and the new Surgeon General."

VETERANS ADMINISTRATION

AID FOR OFFICIALS IN ADVISING VETERANS WHO DESIRE TO ENTER MEDICAL SCHOOL

The Veterans Administration has prepared a digest of articles previously published and has analyzed the data in a bulletin to help officials advise veterans who desire to enter medical school under the G. I. Bill or Public Law 16. The analysis shows, it is said, that veterans stand an average or better chance of completing such training successfully if they meet any, or preferably all, of the following qualifications: (1) obtain grades of B plus or better in their premedical training, (2) make particularly high grades in the natural sciences and (3) enroll in medical schools in the same educational institution in which they completed their premedical work.

In predicting success at medical school on the basis of grades received in courses on natural science, officials of the Veterans Administration emphasized that the quality of work in such courses rather than the quantity of the science courses is the important factor.

The data analyzed by the Veterans Administration disclosed that students who attend medical schools in the same educational institutions where they took their premedical training consistently make better grades than students who transfer from other schools. The percentage of failures also was appreciably lower for "native" students than for transfer students. The Veterans Administration explained the consistently superior accomplishments of "native" students by the fact that medical schools are able to consult personally with premedical faculty members about the qualifications of applicants and thus are in a position to select applicants most likely to succeed.

The bulletin published by the Veterans Administration cautioned that scholastic aptitude tests and the length of premedical training—when considered without relation to other factors—are unreliable in evaluating chances for success in medical school. In one instance scholastic aptitude tests were administered to a thousand prospective medical students. The tests correctly predicted successful completion of medical school only 53 per cent of the time. In fact, 5 per cent of the students whose classroom averages were among the highest made poor showings in their aptitude tests.

Although each year an increasing number of medical schools limit admittance only to students with bachelors' degrees, research studies, it is said, have indicated that the length of premedical training has little bearing on their future accomplishments in the study of medicine. It was concluded from this analysis that the quality rather than the extent of collegiate preparation determines eventual performance in medical school.

VETERANS' TRAINING AND EDUCATION

While World War II veterans are taking training in certain courses financed by other federal appropriations, they are ineligible for training under the GI Bill or the Vocational Rehabilitation Act (Public Law 16). The Veterans Administration's ruling held that training and education provided by the two veterans' training laws was not intended to duplicate training of veterans already enrolled in courses of study and receiving benefits for training from other government appropriations. Accordingly, veterans must select the federal program under which they prefer to enter certain types of training. Certain courses financed by federal appropriations are available to veterans as well as to other persons. These are separate from the training programs established for eligible veterans under Public Law 16 and the GI Bill (Public Law 346). Among such courses are: (1) U. S. Public Health Service training programs for persons receiving fellowships or salaries from state and other grant-in-aid funds derived wholly or in part from federal appropriations; (2) U. S. Maritime Commission training programs; (3) resident training programs in hospitals, clinics and medical or dental laboratories owned or operated by the United States, and (4) residency training for physicians and dentists in the Department of Medicine and Surgery of the Veterans Administration.

The restrictions do not apply to veterans enrolled under either law in the Veterans Administration's training program for

clinical psychologists. These trainees may receive subsistence allowances based on the training which is provided to them in educational institutions. They may be paid from government funds for part time work in Veterans Administration stations where neuropsychiatric veterans are treated. The ruling will not affect veterans training on the job under either law in those federal agencies and establishments approved by the Veterans Administration to offer such training.

The agency said that the instruction does not eliminate possible concurrent payment of benefits for study in a foreign institution under both the GI Bill and the Fulbright Act (Public Law 584, 79th Congress). When veterans complete their training under other federally supported programs, they become eligible to continue their studies or take other training under provisions of the GI Bill or Public Law 16.

PROFESSIONAL LOANS TO VETERANS

About 7 per cent of the World War II veterans who obtained G. I. business loans are in professional and semiprofessional fields such as medicine, dentistry, law, engineering, architecture, nursing, music and designing. Among other fields that veterans entered with the help of government-guaranteed loans were: retailing, 30 per cent; service trades (such as laundries and beauty shops), 20 per cent; transportation, 18 per cent; crafts, 7 per cent; sales agents, 6 per cent; manufacturing, 5 per cent; wholesaling, 4 per cent; finance, insurance and real estate, 2 per cent, and recreation and amusement businesses, 1 per cent. Average amount of each business loan made during a four month survey period was \$3,200. Nearly all the loans granted during the four month period are repayable on a monthly installment basis. Under the G. I. Bill, the Veterans Administration guarantees the lender against loss for 50 per cent of the total loan, up to a maximum of \$2,000 on non-real estate loans and \$4,000 on real estate loans. More than 85,000 G. I. business loans, totaling \$273,000,000, have been approved in the more than two years since the program's inception.

INCREASE PENSIONS FOR VETERANS OF INDIAN WARS

Effective March 1, the Veterans Administration will pay a 20 per cent increase in pensions for veterans of the Indian wars and in death pensions to their dependents. The increase was voted by the current session of Congress and signed into law by President Truman on January 19. Similar 20 per cent increases were granted to veterans and dependents of the Civil and Spanish-American wars in August 1947. Some 790 veterans and 2,200 dependents will benefit by the new law. Under the old rates payments ranged from \$20 to \$100 for veterans of Indian wars and from \$30 up for beneficiaries, depending on the number and relationship.

ENLARGE TUBERCULOSIS HOSPITAL

A contract by the Veterans Administration has been awarded to construct a hundred bed addition and alterations to the veterans' tuberculosis hospital in Livermore, Calif. J. J. Rockefeller, director of the Veterans Administration construction service, announced. The contract calls for a six story building to house one hundred new beds; additions to the kitchen and dining hall building; a new incinerator, and an addition to the laundry. To kill disease-carrying bacteria, ultraviolet lamps are to be installed in the dining hall, recreation room and other areas where patients congregate.

PERSONAL

Dr. Joseph L. Campbell, formerly of Ulster, Pa., has been appointed manager of the veterans' hospital at New Castle County Air Base, Wilmington, Del., to succeed Dr. William J. McCarty, who has been transferred to Lebanon, Pa., to manage a new veterans' hospital. Dr. Campbell served in the Army during the recent war and was awarded the Purple Heart for wounds received during the landings in Normandy, France.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Personal.—Warner W. Carlson, Ph.D., has been appointed associate professor of biochemistry at the Medical College of Alabama, Birmingham. He has been associated with the Mellon Institute of Industrial Research in Pittsburgh since 1939.

Stuart Graves Lecture.—Dr. Elexious T. Bell, professor of pathology, University of Minnesota Medical School, Minneapolis, will deliver the annual Stuart Graves Lecture at the Medical College of Alabama in Birmingham on February 27. This lecture is sponsored by Beta Phi Chapter of Nu Sigma Nu Fraternity.

CALIFORNIA

Reginald Knight Smith Lecture.—The annual Reginald Knight Smith Lecture of the Mount Zion Hospital, San Francisco, will be presented by Dr. Cyril N. H. Long, dean of the Yale University School of Medicine, New Haven, Conn., and Sterling professor of physiologic chemistry, on March 2 at the hospital. His subject will be "The Influence of the Adrenal Cortex on Metabolism."

New Psychiatry Study.—The department of psychiatry of the University of California Medical School, San Francisco, has been awarded a research grant of \$13,392 by the U. S. Public Health Service to support work in the exploration of social situations used in psychotherapy under Dr. Jurgen Ruesch. An attempt will be made to gather precise information on the responses of patients to psychiatric treatment.

School of Public Health Appointments.—The University of California School of Public Health, Berkeley, has announced three appointments. Jacob Yerushalmy, principal medical statistician, states relation division, U. S. Public Health Service, has been appointed professor of biostatistics. Dr. Yerushalmy has recently returned from Denmark, where he served as consultant in the Danish tuberculosis control program. Dr. Dean A. Clark has been appointed lecturer in medical economics. Dr. Clark has recently been at the university for a series of graduate lectures on the administration of medical care programs, following which he returned to his duties as medical director of the Health Insurance Plan of Greater New York. Dr. Edwin H. Lennette, who recently became the director of the virus laboratory, California Department of Public Health, has also been appointed lecturer in public health. Dr. Lennette was a member of the field staff of the International Health Division of the Rockefeller Foundation until 1946, when he became chief of the Medical Veterinary Division of the War Department.

COLORADO

State Rural Health Conference.—The second Colorado Rural Health Conference, sponsored by the Colorado State Medical Society, will be held at the Shirley-Savoy Hotel March 2, beginning at 9 a.m. Subjects under discussion include problems encountered in establishing a county or district health unit, county health councils, the state hospital survey, responsibility of rural communities, preparing nurses for rural work and getting doctors in rural areas through general practice resident training. The honor guest at the luncheon at 12:15 will be Dr. Archie C. Sudan, Denver, formerly of Kremmling, and recent winner of the General Practitioner Award of the American Medical Association.

ILLINOIS

The Eighteenth State Cancer Clinic.—The Illinois director of public health has announced the opening of a state-aided cancer diagnostic clinic at Quincy, thus bringing to eighteen the number of such centers in Illinois. Known as the Adams County Cancer Diagnostic Clinic, the new center is located in the offices of the county health department. Regular clinic sessions will be held the first and third Mondays of each month beginning at 7 o'clock in the evening. The new clinic is under the direction of Dr. Kent W. Barber, with Dr. Frank Cohen serving as pathologist and Drs. Harold Swanberg, Stephen L. Casper and Gordon M. Perisho alternating as the radiologist. The cancer diagnostic clinics maintained by the state department of public health provide free examination and consultation service to all suspected cancer patients referred by private physicians of Illinois.

Chicago

Undergraduate Research Awards.—The Borden Company Foundation, Inc., has contributed \$2,500 to the University of Illinois for the establishment of research awards in medicine. The gifts will be known as the Borden Undergraduate Research Awards in Medicine and will be administered under the direction of Dr. John B. Youmans, dean of the college of medicine. An award of \$500 will be made each year over a period of not less than five years. All students in the graduating class who have carried out undergraduate research in the medical field will be eligible for the award.

Dr. Cole Appointed to Mission to Britain.—Dr. Warren H. Cole, professor and head of the department of surgery at the University of Illinois College of Medicine, has been appointed senior scientist attaché to the United States Mission to Britain for Science and Technology. The mission will be conducted under the jurisdiction of the U. S. Department of State. Dr. Cole, who left Chicago February 8, will serve with the mission for about three months as the representative in surgery. The mission is designed to establish liaison with British scientists in medicine, engineering and chemistry.

Purchase Building for Nutrition Institute.—Northwestern University has announced the purchase of the nine story Dunham building at 450 East Ohio Street, Chicago, which will house the recently established Institute of Human Nutrition, to be directed by Dr. Tom D. Spies, professor of nutrition and metabolism and chairman of the department in the medical school. Purchase was initiated by an advance gift of \$10,000 from Eugene Kettering of the electromotive division of the General Motors Corporation. Raising of funds in the amount of \$1,000,000 to complete the purchase of the building and to provide operating funds for the board's program of research is now under way.

First Industrial Conference on Alcoholism.—The first Industrial Conference on Alcoholism will be held in the Morrison Hotel, Chicago, on Monday, March 23. Sponsored by the Chicago Committee on Alcoholism, the conference has been designed to bring to the attention of industrial leaders throughout the country facts pertaining to the problem of alcoholic employees and to discuss ways and means of overcoming the problem. In the morning session two speakers will discuss "Alcoholism in Industry." Dr. John L. Norris of the Eastman Kodak Company, Rochester, N. Y., will speak at the luncheon. In the afternoon various types of individual treatment will be discussed and the work of the Yale School of Alcohol Studies, the Keeley Institute treatment and rehabilitation centers, as well as the Alcoholics Anonymous program, will be outlined. Industry's part in the problem will be discussed. Reservations for attending the technical session and the luncheon may be made by writing Walter O. Cromwell, vice president, Chicago Committee on Alcoholism, 816 South Halsted Street, Chicago 7.

Associate Deans Appointed.—Dr. Wright R. Adams, associate professor of medicine, and Merle C. Coulter, Ph.D., professor of botany, have been appointed associate deans in the division of biologic sciences at the University of Chicago. Working under Dr. Lowell T. Coggeshall, dean of the division, Dr. Adams, who has been in the department of medicine at the university for the past sixteen years, will be responsible for the clinical departments and the school of medicine. He will also assist in the planning of the new hospital buildings at the university: the Nathan Goldblatt Memorial Hospital for Cancer, the Charles Gilman Smith Hospital for Infectious Diseases and the Gertrude Dunn Hicks wing to Albert Merritt Billings hospital. Dr. Coulter will have charge of the nonclinical departments in the biologic sciences—anatomy through zoology. Dr. Coulter, who has been associated with the university for thirty years, received his Ph.D. degree from the university in 1919, became an assistant professor in 1921 and was appointed a full professor of botany in 1931.

IOWA

Dr. DeGowin Appointed to Committee on Blood.—Dr. Elmer L. DeGowin, associate professor of internal medicine at the State University of Iowa College of Medicine, Iowa City, has accepted assignment to the Committee on Blood and Blood Derivatives of the National Research Council's Division of Medical Sciences. The committee, according to Dr. DeGowin, is to advise public agencies on blood transfusions, blood derivatives, and plasma fractions. The University of Iowa College of Medicine has been a center for research in this field for the past decade. The National Research Council committee will help set up the new national blood program of the American

Red Cross, supplying blood for civilian, veteran and public health service hospitals. It will also advise the Army, Air Forces, Navy, U. S. Public Health Service and Atomic Energy Commission.

LOUISIANA

Personal.—Dr. Fayette C. Ewing, Pineville, has recently received a certificate from the Alumni Association of Jefferson Medical College of Philadelphia in recognition of "sixty-three years of faithful service in the traditional ideals of the medical profession."

Director of Postgraduate Pediatric Program.—Dr. Sidney S. Chipman, formerly of Norwalk, Conn., has been engaged by Louisiana State University School of Medicine, New Orleans, as associate professor of pediatrics. He will be director of the postgraduate extension program in pediatrics in the state on a joint appointment of the state university and state board of health.

MICHIGAN

One Thousand Measles Cases a Week.—The epidemic of measles, which started three months ago in Kalamazoo city and county, has spread to surrounding counties, Berrien, Kent, Cass, Ottawa, Calhoun, Barry, Eaton and Ingham being the hardest hit. A total of 1,014 cases were reported to the Michigan Department of Health during the week ending January 30. There were 66 cases of measles during the same week last year, and 628 during the same week in 1946, an epidemic year.

Conference on Venereal Disease.—A one day conference on modern diagnosis and treatment of venereal disease will be held at the Detroit Intensive Treatment Center, Herman Kiefer Hospital, Detroit, March 13 beginning at 9 a.m. Physicians of Ann Arbor, Detroit and the Michigan Department of Health will speak. Among the subjects are treatment of early syphilis, syphilis of the central nervous system, syphilis and marriage, syphilis and pregnancy and interpretation of serologic tests.

MISSOURI

Heart Association Formed.—The Missouri Heart Association was organized Dec. 14, 1947 in Jefferson City at a meeting of the former Heart Committee of the Missouri State Medical Association. Dr. A. Graham Asher, Kansas City, was elected president, Dr. C. Braxton Davis, Nevada, secretary, and Dr. Glen W. Hendren, Liberty, treasurer.

NEW YORK

Cancer Society Grants Since September.—The New York State division of the American Cancer Society, Inc., announced January 23 that it had approved projects totaling \$172,597.71 since Sept. 1, 1947. Largest of the grants included \$26,466.06 to the Monroe County branch administration education service, \$21,900 to the Broome County free cancer detection centers, \$21,140.10 to the Erie County chapter educational program, \$19,960 to the Syracuse Memorial Hospital tumor clinics, \$15,050 to Cornwall Hospital for replacing an obsolete x-ray unit and opening a detection center and \$14,000 to Nyack Hospital for its radiology course.

Licenses Revoked and Suspended.—The board of medical examiners of the state education department reports the following action taken by the board of regents: The license of Gaspare Genova, 1257 Seventieth Street, Brooklyn, has been suspended for one year, effective Dec. 11, 1947. The license of Leopold W. A. Brandenburg, 2802 Hudson Boulevard, Union City, N. J., which permitted him to practice in the state of New York, has been revoked, effective Nov. 25, 1947. Others whose licenses have been revoked are Anne Elizabeth Kuhner, 52 Gramercy Park North, New York, effective Dec. 5, 1947, and Boris Schleifer, 2001 Strauss Street, Brooklyn, effective Dec. 3, 1947.

New York City

Construct Emergency-Accident Wing.—Roosevelt Hospital began this month the construction on Fifty-eighth Street near Ninth Avenue of a two story and basement emergency-accident building at the estimated cost of \$600,000. The first floor will be devoted to emergency and accident services, the second to ward service and the basement to garage space for ambulances. The building is to be called the James I. Russell Memorial building in honor of the surgeon who died in 1944 after being associated with the hospital for more than forty years.

Personals.—Dr. Clarence E. de la Chapelle, associate dean of New York University College of Medicine, has been appointed a director of medicine at Lenox Hill Hospital. He has been for fifteen years chief of the hospital's cardiovascular service and clinic, and will continue to serve in his capacities as associate dean, director of the postgraduate division and professor of

clinical medicine at the college.—Dr. Paul W. Lapidus, formerly assistant professor of orthopedic surgery of the New York Polyclinic Medical School and Hospital, has been promoted to the rank of clinical professor of orthopedic surgery.

University Appointments.—A series of personnel changes on the staff of the Faculty of Medicine of Columbia University have been announced. Dr. Alexander B. Gutman, assistant professor, was promoted to associate professor of medicine. Also elevated to an associate professorship was Dr. Dan H. Moore, former assistant professor of anatomy. Dr. Ralph A. Deterling Jr. was appointed assistant professor of surgery and Dr. Louis David Zeidberg was named assistant professor of epidemiology, both appointments effective January 1. The appointment of Dr. James A. Miller, New York, to replace Dr. Eugene H. Pool, New York, on the joint administrative board of the Columbia-Presbyterian Medical Center was also announced. Dr. Pool resigned recently from the board of trustees of Columbia University.

Report of Eye-Bank.—The Eye-Bank for Sight Restoration, Inc., at the close of its second year announced in January that hospital affiliations in the United States had grown to one hundred and fifty and that contributions through membership support had increased 50 per cent. Affiliate eye banks have been established in Boston and New Orleans. Glaucoma clinics and other special types of clinics were said to have increased in number. Dr. R. Townley Paton, vice president of the organization, reported that in two years the eye bank had accepted 310 eyes from the public and that 90 per cent had been used for transplantation. Eyes that could not be certified as suitable for the operation were used for research. During the past year the eye bank has supplied corneal material to the Midwest and Midsouth and has sent eyes to Ohio, California, Michigan, Illinois, Pennsylvania and Texas.

OHIO

Dr. Kline Given Medal for Research.—Dr. Benjamin S. Kline, Cleveland, was given a gold medal in December by his associates in Phi Lambda Kappa for his "outstanding work in medical research." Dr. Kline is chief pathologist at Mount Sinai Hospital and a member of the faculty at Western Reserve University School of Medicine. He is most widely known for his development of a simplified slide test for detection of syphilis.

PENNSYLVANIA

State Society Honors Centenarian.—The Pennsylvania State Medical Society on February 2 presented to Mrs. Bridget B. Corcoran, Hawley, a plaque on her one hundred and third birthday. Dr. Arno C. Voight, her family physician, made the presentation. A native of Eire, Mrs. Corcoran settled in Hawley in 1868. This is the centennial year of the state medical society.

Philadelphia

Allergy Society Meeting.—The annual dinner meeting of the Philadelphia Allergy Society will be held on Wednesday, February 25, 6:30 p.m., at 2601 Parkway. Dr. Bret Ratner of New York will be the guest speaker.

Dr. Yater to Lecture.—Dr. Wallace M. Yater, formerly of the Georgetown University School of Medicine, Washington, D. C., and director of the Yater Clinic there, will speak on "Coronary Artery Disease of Young Men" on February 27 at the Klahr Auditorium of Hahnemann Medical College. The lecture is sponsored by the Beta Zeta Chapter of the Phi Delta Epsilon.

Dr. Shields Warren Speaks on Atomic Energy.—Dr. Shields Warren, Boston, delivered the Alpha Omega Alpha Annual Lecture at Jefferson Medical College, Philadelphia, February 19 at 8:30 p.m. on "Medical Aspects of Atomic Energy." Dr. Warren is director of the division of biology and medicine of the Atomic Energy Commission, pathologist to the New England Deaconess Hospital and assistant professor of pathology at Harvard Medical School.

Clinic for Practicing Physicians.—The board of managers of the Pennsylvania Hospital announced the opening on February 16 of the Benjamin Franklin Clinic on Ninth Street at Pine. The staff consists of chiefs of the various services of the Pennsylvania Hospital and their associates. The founding group is composed of Drs. Paul A. Bishop, A. Reynolds Crane, Gailfield G. Duncan, John B. Flick, Leon Herman, Robert A. Kimbrough, Joseph B. VanderVeer and Adolph A. Walking. The clinic is concerned with the medical care of private patients and offers diagnostic and consultative aid to practicing physicians. Treatment will be undertaken on the request of the referring physician.

TEXAS

Installs Chapter at Baylor.—Alpha Kappa Kappa Medical Fraternity installed Chapter Beta Upsilon at Baylor Medical School, Houston, on January 17. National officers officiated at the installation at the Rice Hotel. A banquet attended by eighty of the state alumni followed the ceremony.

Teaching and Research Tuberculosis Unit.—The sum of \$300,000 for a teaching and research unit in tuberculosis will become available to the University of Texas Medical Branch, Galveston, under the terms of the will of the late Mrs. Rosa H. Ziegler of Galveston. The Medical Branch has been named residual legatee, with the university regents as trustees. Under the terms of the will, the unit will be named the Henry and Rosa H. Ziegler Tuberculosis Hospital and will afford facilities for teaching and research in acute and chronic tuberculous conditions.

Appointed Director of Research.—Dr. Benjamin B. Wells, formerly dean of the University of Arkansas School of Medicine, Little Rock, has been appointed director of research and head of the department of clinical pathology at the University of Texas, Houston. He was graduated from Baylor University College of Medicine, Houston, 1935, and was appointed a Mayo Foundation fellow in biochemistry and physiology at the University of Minnesota, Minneapolis. In 1941 he received his Ph.D. from the University of Minnesota, Minneapolis, and then studied endocrine physiology at the Carnegie Institution of Washington. After forty-two months of service in the U. S. Army, he went in 1945 to the University of Arkansas School of Medicine, where he was clinical pathologist and director of medicine.

Annual Spring Clinical Conference.—The Dallas Southern Clinical Society will hold its seventeenth annual Spring Clinical Conference March 15-18 at Hotel Adolphus and the Baker Hotel, Dallas. There will be general assemblies, afternoon clinics, roundtable conferences, symposiums and a clinical pathologic conference. Guest physicians are F. Bayard Carter, Durham, N. C., obstetrics and gynecology; Charles D. Creevy, Minneapolis, urology; Frederick A. Davis, Madison, Wis., ophthalmology; William Dock, Brooklyn, medicine; Howard K. Gray, Rochester, Minn., surgery; Charles A. Janeway, Boston, pediatrics; Louis H. Newburgh, Ann Arbor, Mich., medicine; Reginald H. Smithwick, Boston, surgery; Arthur P. Stout, New York, pathology; Oscar Swineford Jr., Charlottesville, Va., allergy; W. Walter Wasson, Denver, radiology, and Henry L. Williams, Rochester, Minn., otolaryngology. Post-graduate lectures will be held from 11 a.m. to 12:15 p.m. March 16-18. The registration fee of \$20 covers admission to all features of the conference.

WEST VIRGINIA

Personals.—Dr. James K. Pickens, Charleston, has been appointed part time director of the division of cancer control of the state health department, succeeding Dr. Paul R. Gerhardt, who recently accepted appointment as director of the New York state division of cancer control at Albany. —Dr. Russell B. Bailey, Wheeling, who was recently named chairman of the executive committee of the West Virginia Cancer Society, has been appointed chairman of the West Virginia State Medical Association's cancer committee to succeed the late Dr. J. Ross Hunter, Charleston, and a member of the board of directors of the American Cancer Society to fill Dr. Hunter's unexpired term. —Dr. Robert L. Smith, Charleston, acting director, bureau of tuberculosis control, state department of health, left February 1 to study at the University of Michigan School of Public Health. Dr. Charles L. A. Wehr, U. S. Public Health, San Francisco, will succeed Dr. Smith as acting director.

Deadlines for Hospital Construction.—Applications for any part of West Virginia's allocation of \$1,555,350 for hospital and health center construction must be received by dates set up by the state health department. Community priority AA group must submit applications not later than March 1, 1948, communities in group A by April 1, group B on or before May 1, group C by June 1 and group D by July 1. This step was taken in view of the fact that the state's share of the funds appropriated under the provision of the Hill-Burton hospital construction act must be used by June 30, 1949. Deadline dates do not affect the priority status of any of the hospital service areas or the subsequent annual grants. According to Dr. Newman H. Dyer, state health commissioner, no project may be awarded more than 50 per cent of the funds available to the whole state in any one year. The state plan for the construction of hospitals and health centers has been approved by the State Advisory Committee on Hospital Construction.

WISCONSIN

Dr. Harper Day.—The Wisconsin State Board of Health and the State Medical Society of Wisconsin sponsored Dr. Harper Day, January 31, in honor of Dr. Cornelius A. Harper, veteran public health officer. Besides an afternoon program commemorating public health progress in Wisconsin, a reception was given in honor of Dr. and Mrs. Harper in Madison with a dinner in the evening. On the dinner program Dr. Harry B. Mustard, Commissioner, New York City Health Department, and dean of public health at Columbia University, spoke on "The Development of State and Local Health Services." Officials of departments of health of neighboring states were guests of honor. Dr. Harper was officially ending his forty-seven years of public health service in Wisconsin, thirty-nine of which he served as state health officer. A native of Wisconsin, Dr. Harper obtained his medical degree from Columbian Medical College, now George Washington University Medical School, Washington, D. C., in 1893. He was appointed to the state board of health in 1901 and in 1904 was made state health officer. He carried forward a program of disease prevention, promoted health legislation and expanded the department. In 1943 he resigned as state health officer but was retained as medical specialist in public health. Among the valuable services he continued to render was the preparation of an authoritative history of public health in Wisconsin, being an actual compilation of the minutes of the State Board of Health since its inception in 1876.

GENERAL

Personal.—Mildred W. S. Schram, Ph.D., who has served the International Cancer Research Foundation as secretary since its organization in June 1932, resigned effective January 15. This foundation was reorganized and renamed the Donner Foundation two years ago.

Medical Public Relations Meeting.—The Council of the New England States Medical Societies will meet March 7 from 1:30 to 5 p.m. at the Copley Plaza Hotel, Boston, to discuss "The New England Doctor and His Public." The officers of every state, county and district medical society in New England, the members of committees on public information, public relations, public policy and radio, and any New England physician interested in learning more about medical public relations are invited to attend. Consultants will be outstanding specialists in radio, press and public health.

Dietetic Association Award.—An award for outstanding accomplishment, including a grant of \$1,000, was presented February 6 to the American Dietetic Association by the Nutrition Foundation, New York. The award, the first of its type to be given by the Nutrition Foundation, was authorized by the group's board of trustees for the purpose of giving dietitians greater recognition for their professional service to the public. The citation read in part, "In recognition of the leadership, inspiration and diligence of its members in applying and in developing the science of nutrition in hospitals, government service, food clinics, public health agencies, school lunchrooms, colleges, universities and industrial organizations, for the advancement of human health."

Blood Bank Association Meetings.—At a meeting of the executive committee of the American Association of Blood Banks in Dallas, Texas, January 31, plans were made for the annual meeting in Buffalo, August 26-28, immediately following the meeting of the International Hematology Society there. The association was organized Nov. 19, 1947, at Dallas (THE JOURNAL, Dec. 27, 1947, p. 1161). Membership is of two classes: institutional membership is available to ethical, independently operating and policy-making, nonprofit institutions, including those operated by American Medical Association-registered hospitals engaged in blood banking. Individual membership is open to any person interested in blood banking. Information may be obtained from the secretary, American Association of Blood Banks, 3301 Junius Street, Dallas, Texas.

Court Fines Manufacturers of Surgical Bandages.—The Attorney General has announced that the district court at Boston, February 5, imposed fines totaling \$23,001 in a criminal antitrust case involving the major manufacturers in the United States of surgical bandages. This followed pleas of nolo contendere by all of the corporate and individual defendants. The fines imposed by Judge George Sweeney were as follows: Johnson and Johnson, \$5,000; Johnson and Johnson International, \$5,000; Kendall Co., \$5,000; Parke, Davis & Co., \$5,000; Earl E. Dickson, vice president, Johnson & Johnson, \$1,000; L. H. Nichols, manager of hospital dressings, the Kendall Company, \$1,000; Arthur Clapham, director of overseas operations, Johnson & Johnson, and president of Johnson &

Johnson International, \$500; Charles K. Perkins, general sales manager, the Kendali Company, \$500; E. Briar, secretary and foreign sales manager, Parke, Davis & Co., \$1. The indictment, which was returned Nov. 21, 1946 by a Grand Jury at Boston, charged the defendants with a conspiracy to restrain domestic and foreign trade through an agreement to fix the prices of surgical dressings. Assistant Attorney General John F. Sonnett, in charge of the antitrust division, stated: "The defendants in this case produced and sold \$35,000,000 of surgical dressings in 1945, which was about 75 per cent of the total in the United States. It is believed that the indictment has already had the effect of eliminating restraints in this industry. The fines assessed should further encourage genuine competition in this field. It is important that purchasers should be able to obtain these indispensable products on reasonable terms."

Inter-American Cardiological Congress.—The third Inter-American Cardiological Congress, sponsored by Michael Reese Hospital, Chicago, will be held in Chicago at the Michael Reese Hospital and at the Stevens Hotel from June 13 to 17. This congress is under the auspices of the Inter-American Society of Cardiology and the National Heart Associations of the Western Hemisphere. Official members are the delegates chosen by the National Heart Associations or, in a country in which there is no heart association, by the national medical society. The names of proposed delegates must be submitted to the president of the congress for approval before appointment can be made. Active members are physicians approved by the National Heart Associations or in some Latin-American countries by Latin-American members of the Inter-American Society of Cardiology's board of directors. All members outside the Western Hemisphere will be appointed by the president of the congress. Physicians wishing to participate in the congress are asked to fill out an application blank and return it together with the \$14 registration fee to the office of the III Inter-American Cardiological Congress, Michael Reese Hospital, Twenty-Ninth Street and Ellis Avenue, Chicago 16, not later than April 1. The fee may be made payable to Dr. Richard Langendorf, secretary. Official languages of the Congress will be English, French, Portuguese and Spanish. Local cooperating institutions will be the Institute of Medicine of Chicago, Chicago Medical Society, Chicago Society of Internal Medicine, Chicago Pediatric Society and the medical schools of the universities of Chicago, Illinois, Loyola and Northwestern.

Annual Accident Toll.—The National Safety Council reports that 100,000 persons died in accidents during 1947 and that 10,500,000 were injured, with the resulting economic cost of \$6,700,000,000. The 1947 toll is 2 per cent above that for 1946. Home accidents deposed traffic accidents as the nation's number one killer, and all accident classifications except traffic and military personnel showed increases. The council pointed to a 4 per cent decrease in traffic deaths as the most encouraging spot in the accident picture despite a 9 per cent increase in travel. Deaths from accidents in 1947 as compared to 1946 were as follows:

	1947	1946	Change
All accidents	100,000	98,033	+ 2%
Motor vehicle	32,000	33,411	- 4%
Home (civilian)	33,500	32,500	+ 3%
Occupational (civilian)	17,000	16,500	+ 3%
Public (civilian; not motor vehicle)	19,000	17,000	+ 12%
Military personnel	1,600	2,000	- 20%

The all-accident death rate was 69.7 per hundred thousand population, some of the causes of death being falls, 26,900; burns, 8,700; drownings, 7,900; firearms, 2,600, and catastrophes in which the toll was at least five lives, 2,100. Seven catastrophes caused 50 or more deaths—the Texas City explosion, the Texas-Oklahoma tornado in April, the Centralia, Ill., coal mine explosion, the Gulf Coast hurricane in September and three airline crashes. Traffic accidents caused also about 1,100,000 non-fatal injuries. Among cities with 200,000 population, Jacksonville, Fla., showed the largest reduction in traffic fatalities (54 per cent). The home accident death total was 3 per cent above that of 1946. Disabling injuries from home accidents numbered 5,000,000, and wage loss, medical expense and the overhead costs of insurance totaled about \$700,000,000. There were about 3 per cent more deaths from occupational accidents than in 1946. While all industrial employment increased about 5 per cent, disabling injuries from accidents at work numbered about 2,050,000. The economic loss from occupational accidents was about \$2,500,000,000. Coal mine deaths rose to 1,039 in the first eleven months of 1947, 22 per cent above the 1946 figure. Railroad employee fatalities were 632 in the same period, an increase of 4 per cent. Fatal airplane accidents in the domestic passenger-carrying operations of scheduled air transports numbered six with a death toll of 217, including 199 passengers, 17 crew members and 1 other person.

CANADA

Personal.—Dr. Thomas C. Routley, Toronto, has received the insignia of Commander, Civil Division of the Most Excellent Order of the British Empire (C.B.E.), from His Majesty the King. Dr. Routley received the award for his service during World War II at a ceremony held by His Excellency the Governor General of Canada at Government House, Ottawa, February 10.

Clinical Meeting.—A clinical evening meeting will be held at the Royal Victoria Hospital, Montreal, on March 5, for the Montreal Medico-Chirurgical Society. On March 19, Dr. Bernard B. Raginsky, Montreal, will address the society in its own rooms on "Psychosomatic Medicine—Twenty Years' Experience," and Dr. Fraser B. Gurd, Montreal, will speak on "Twenty-Five Ways of Getting Into Trouble Treating Fractures."

Award for Papers on Shoulder Lesions.—The secretary of the Province of Quebec, the Honorable Omer Côté, recently announced the various winners in the literary and scientific competition for 1947. Dr. Herbert F. Moseley of Montreal received the first prize of \$800 in the field of medicine for his series of papers on surgery of shoulder lesions. The winners were selected by a jury whose members conveyed their decisions in writing to the secretary of the province.

LATIN AMERICA

Medical Congress.—The Second Congreso Peruano de Cirugia will be held in Lima March 15-20, under the auspices of the government of Peru, with Dr. Alberto Sabogal, president. Official speakers are: Dr. Guillermo Gastaneta on "Inguinal Hernia"; Dr. Fortunato Quesada on "Assistance of the Traumatized in Peru," and Dr. Carlos Peschiera on "Abscess of the Lung." The fee is \$15 (100 gold soles). Information is obtainable from the Committee on Organization, Camana 773, Lima, Peru.

New Medical Journal.—*Archivos Argentinos de Kinesiología* of Buenos Aires, official organ of the School of Kinesiology of the Faculty of Medical Sciences of Buenos Aires, recently appeared. Drs. Juan M. Nagera and Belisario A. Moreno are editor and associate editor, respectively, and Drs. Claudia O. Ceci and Armando G. Cotone are assistant editors. The first issue of November 1947 includes articles by Drs. Nicanor Palacios Costa of Buenos Aires, Pablo Izaguirre, Carlos Fonso Gandolfo, Elena T. de Albino, Juan M. Nagera, Belisario A. Moreno and Jaime Catcula.

CORRECTION

Heparin in Pitkin Menstruum Not Given Intravenously.—The answer to the last question on page 303 in *THE JOURNAL*, January 31, stated that heparin may be given subcutaneously or intravenously in the Pitkin menstuum. This was an error. Heparin may be given subcutaneously or intramuscularly in the Pitkin menstuum but not intravenously.

Marriages

ROBERT JOSEPH BARRETT Jr., Washington, D. C., to Miss Agnes Gertrude McGann of Weston, Va., Sept. 20, 1947.

LAVINIA GOULD MACKEYE, Ann Arbor, Mich., to Mr. Ezra G. Benedict Fox of Tenafly, N. J., at Baltimore recently.

WALTER DICK BIGFORD, Port Edwards, Wis., to Miss Frances Emilie Hambrick at Glen Wilton, Va., recently.

BEN O. STANDS, La Fontaine, Ind., to Miss Marjorie Lee Powell in Elizabethtown, N. C., Oct. 23, 1947.

CHARLES H. LAPAN, Las Animas, Colo., to Miss Ferne Garon of Chicago at Pueblo, Colo., Aug. 31, 1947.

PASQUALE S. TEST, Youngstown, Ohio, to Miss Jeanne Catherine Reed of Butler, Nov. 8, 1947.

DONALD STERLING RAINES, Syracuse, N. Y., to Miss Marian Reinhardt of Brooklyn, Sept. 20, 1947.

Harry L. Mills, Gouverneur, N. Y., to Mrs. Margaret Stevens of New York, Dec. 8, 1947.

RAYMOND M. WETRICH to Miss Mary Jane Wallace, both of Rochester, N. Y., Sept. 20, 1947.

MARTIN HERBERT ZWERLING to Miss Nancy Ann Solomon, both of Brooklyn, recently.

PETER ROODY, Astoria, L. I., N. Y., to Miss Lula Athans, Sept. 21, 1947.

Deaths

Percy Tilson Magan † Los Angeles; born in Gorey, Ire., Nov. 13, 1867; University of Tennessee College of Medicine, Memphis, 1914; became dean and professor of medicine at the College of Medical Evangelists, where he served as a trustee and professor of public health and in 1934 was appointed head of the newly created department of legal and cultural medicine; in 1928 became president at the college, serving until his retirement and election to the position of president emeritus in 1942; professor of history from 1891 to 1901 and dean from 1899 to 1901 at Battle Creek College; dean of Emmanuel Missionary College, Berrien Springs, from 1901 to 1904, when he became dean of the Nashville Agricultural Normal Institute at Madison, Tenn., serving until 1915; an Affiliate Fellow and from 1927 to 1930 member of the House of Delegates of the American Medical Association; fellow of the American College of Physicians; member of the American Hospital Association, National Tuberculosis Association, Southern California Medical Association, League for Conservation of Public Health and the Society of American Bacteriologists; a trustee of the Los Angeles County Medical Association and formerly vice president of the California Medical Association; chairman of the anatomy board, southern division, department of public health; served as a member of the board of medical examiners; trustee of the medical board of Los Angeles County General Hospital; editor of *Health Magazine*; died Dec. 16, 1947, aged 80, of heart disease.

Julian Lamar Rawls † Norfolk, Va.; born in Carrsville, Va., July 26, 1881; Medical College of Virginia, Richmond, 1904; the ninetieth president of the Medical Society of Virginia; past president of the Norfolk County Medical Society, the Seaboard Medical Association, the Southeastern Surgical Congress and the Association for the Study of Neoplastic Diseases; fellow of the American College of Surgeons; held the rank of lieutenant commander in the Naval Reserve from 1933 to 1939 and later surgeon in the U. S. Public Health Service Reserve; in 1941 member of the House of Delegates of the American Medical Association; a vice president of the Virginia Cancer Foundation; during World War II chairman of the medical division of the procurement and assignment service of the Second Congressional District; since 1910 on the staffs of St. Vincent De Paul, the Norfolk General and the Leigh Memorial hospitals, and at various times was president of each; was largely responsible for the establishment in 1938 of a diagnostic tumor clinic; at the time of his death was on the Governor's Advisory Legislative Council on Medical Matters; in October 1947 received the first J. Shelton Horsley Memorial Award of Merit, presented by the Virginia Division of the American Cancer Society in recognition of his contributions to the cause of cancer control; president of the Tidewater Hospital Service Association since its inception in 1935; died January 18, aged 66.

Jefferson Cumley Pennington † Nashville, Tenn.; born in Rockford, Ala., March 8, 1892; Vanderbilt University School of Medicine, Nashville, 1923; specialist certified by the American Board of Urology, Inc.; president of the Mid-South Post Graduate Assembly; past president and one of the founders of the Southeastern Urological Association; served as secretary and chairman of the urologic section of the Southern Medical Association; past president of the Middle Tennessee Medical Association; member of the Southeastern Surgical Congress and the American Urological Association; fellow of the American College of Surgeons; served during World War I; instructor in clinical urology at the Vanderbilt University School of Medicine; affiliated with the Vanderbilt University, Nashville General, Protestant and St. Thomas hospitals; urologist, Davidson County Tuberculosis Hospital and Florence Crittenton Home; consulting urologist to the Central State Hospital; died in the Nashville General Hospital Dec. 12, 1947, aged 55, of coronary thrombosis.

William John L. Lyster † Colonel, U. S. Army, retired, Washington, D. C.; born in Detroit on July 9, 1869; Detroit College of Medicine, 1894; received the degree of doctor of public health from the University of Pennsylvania, Philadelphia, 1911; fellow of the American College of Surgeons; joined the medical corps of the U. S. Army in 1900; served in China and on the Mexican border; during World War I was awarded the Order of Companion of St. Michael and St. George by the British after serving as liaison officer between American and English medical forces; later served at various army posts throughout the United States; retired Sept. 30, 1941 at his own request after thirty years' service; at one time professor of

military science and tactics at the Harvard Medical School in Boston; developed the "Lyster Bag" for sterilizing drinking water; died May 20, 1947, aged 77, of coronary thrombosis.

William H. Chaffers, Lewiston, Maine; born in Worcester, Mass., 1887; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Canada, 1909; member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology and of the New England Otolological and Laryngological Association; specialist certified by the American Board of Otolaryngology; formerly a member and at one time chairman of the board of education; director of the Manufacturers' National Bank; affiliated with St. Mary's General Hospital, where he died Nov. 29, 1947, aged 60, of coronary thrombosis.

Arnt Grundtvig Andersen † Minneapolis; born in Minneapolis Dec. 31, 1881; University of Minnesota College of Medicine and Surgery, Minneapolis, 1934; fellow of the American College of Surgeons; served during World War I; for his services during World War II was awarded the selective service medal and certificate of merit; affiliated with the Lutheran Deaconess and Swedish hospitals; died in the University Hospital Nov. 1, 1947, aged 66, of air embolism and metastatic carcinoma of the liver, following an intestinal resection and emergency tracheotomy.

James Baird † Flint, Mich.; Detroit College of Medicine, 1896; affiliated with Hurley, St. Joseph and Women's hospitals; died in Goodrich (Mich.) General Hospital Nov. 20, 1947, aged 75, of cirrhosis of the liver.

Angus J. Barter, Tacoma, Wash.; Washington University School of Medicine, St. Louis, 1908; member of the American Medical Association; died Nov. 13, 1947, aged 72.

Charles Herbert Bruner † Greenfield, Ind.; Indiana University School of Medicine, Indianapolis, 1915; served during World War I; for many years president of the city school board; member of the city board of health; past president of the Hancock County Medical Society; died Nov. 16, 1947, aged 60, of myocardial failure.

Jerome Stuart Chaffee † Sharon, Conn.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; fellow of the American College of Surgeons; served as health officer and medical examiner; affiliated with the Sharon Hospital; died Nov. 26, 1947, aged 74, of carcinoma of the prostate.

Ralph Edmund Conn, Uniontown, Pa.; Medico-Chirurgical College of Philadelphia, 1913; died Nov. 27, 1947, aged 57.

Charles C. Copeland, North Madison, Ind.; University of Louisville (Ky.) Medical Department, 1889; member of the American Medical Association; died Nov. 20, 1947, aged 83, of heart disease.

J. Willis Demarest, Hackensack, N. J.; University of Louisville (Ky.) School of Medicine, 1927; member of the American Medical Association; city and school physician; affiliated with the Hackensack Hospital; died Nov. 18, 1947, aged 48, of coronary heart disease.

James W. Dixon, Golconda, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; served one term as mayor of Golconda; died in the Good Samaritan Hospital in Mount Vernon, Nov. 15, 1947, aged 89, of prostatic obstruction and bronchopneumonia.

William C. Frost, Uniontown, Pa.; University of Pittsburgh School of Medicine, Philadelphia, 1908; died Nov. 26, 1947, aged 72, of carcinoma of the colon.

Fortunat Gagnon, Providence, R. I. (licensed in Rhode Island, by years of practice); died Nov. 16, 1947, aged 89, of cardiovascular disease.

Edward Thomas Gallagher, St. Louis; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1916; member of the American Medical Association; served during World War I; for many years affiliated with the Veterans Administration Hospital in Jefferson Barracks, Mo.; died Nov. 17, 1947, aged 70.

Arthur Edison Gammage † Rio, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1906; junior professor of gynecology and obstetrics at his alma mater from 1908 to 1912; served during World War I; from 1919 to 1923 superintendent of the Municipal Contagious Disease Hospital in Chicago, where he was on the staffs of the Illinois Masonic and Edgewater hospitals; died in Fort Lauderdale, Fla., Dec. 31, 1947, aged 66.

Dan Fulkerson Glasgow † Tyrone, Pa.; Jefferson Medical College of Philadelphia, 1909; died Dec. 23, 1947, aged 65, of carcinoma.

Walter Ashley Glines • San Juan, Puerto Rico; College of Physicians and Surgeons, Baltimore, 1906; fellow of the American College of Surgeons; served at the Panama Canal project and was decorated by the French government at the beginning of the century; served during World War I; member of the Insular Board of Health; attending urologist, University Hospital of the School of Tropical Medicine, Presbyterian Hospital and the U. S. Public Health Service; died at his home in Santurce Nov. 16, 1947, aged 67, of arteriosclerosis.

Alexander R. Hall • St. Paul; McGill University Faculty of Medicine, Montreal, Canada, 1900; formerly on the faculty of the University of Minnesota Medical School, Minneapolis; past president of the Minnesota Academy of Medicine; for many years on the staff of Ancker Hospital; died Nov. 27, 1947, aged 73.

James Kiah Hamilton • Alameda, Calif.; Medical Department of the University of California, San Francisco, 1903; an Affiliate Fellow of the American Medical Association; past president of the Alameda County Medical Society; served in France during World War I; for many years member of the city board of health; formerly on the staff of the Alameda Sanatorium; died Dec. 17, 1947, aged 67, of coronary occlusion.

Loring Hammer, Luray, Va.; Medical College of Virginia, Richmond, 1909; member of the American Medical Association; director of the First National Bank; died in Page Memorial Hospital Nov. 23, 1947, aged 64, of chronic nephritis and encephalitis.

Daniel Clyde Hankey • Council Bluffs, Iowa; Harvard Medical School, Boston, 1915; city health officer; served with the American Red Cross in the Balkan countries during World War I; affiliated with the Jennie Edmundson Memorial Hospital; died Nov. 20, 1947, aged 64, of coronary sclerosis.

Dausa Dow Hartwell, Marion, Ill.; St. Louis College of Physicians and Surgeons, 1901; served during World War I; died Nov. 18, 1947, aged 69, of cerebral hemorrhage.

Henry Heiman • New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; formerly professor of pediatrics at the New York Polytechnic Medical School and Hospital; member and formerly vice president of the American Pediatric Society; for many years affiliated with Mount Sinai Hospital, where he died Nov. 16, 1947, aged 82, of arteriosclerosis.

Francis Freeman Henderson • Boston; Tufts College Medical School, Boston, 1911; affiliated with the Boston City Hospital; died in Milton Nov. 20, 1947, aged 61, of acute cardiac dilatation and diabetes mellitus.

James Isaac Huggins • Bowling Green, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; died Nov. 19, 1947, aged 75, of myocarditis.

Ethan Alexander Ish, Waterloo, Ind.; Chicago College of Medicine and Surgery, 1909; member of the American Medical Association; served during World War I; died Nov. 19, 1947, aged 70, of cardiac decompensation and hypertension.

Oliver M. Johnson, Water Valley, Ky.; Eclectic Medical Institute, Cincinnati, 1885; died in Fulton Nov. 24, 1947, aged 85, of pneumonia.

Samuel Edward Johnson, Tampa, Fla.; Meharry Medical College, Nashville, Tenn., 1908; died recently, aged 66.

William Charles Keller, Philadelphia; Medico-Chirurgical College of Philadelphia, 1915; member of the American Medical Association; served during World Wars I and II; affiliated with the Philadelphia General Hospital; died in the U. S. Naval Hospital Nov. 21, 1947, aged 56, of heart disease.

Walter Norwood Keylor, Leacock, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the American Medical Association; served during World War I; died in Lancaster (Pa.) General Hospital Nov. 6, 1947, aged 79.

Avery Ionia Lewis, Mouthcard, Ky.; Tennessee Medical College, Knoxville, Tenn., 1908; died in the Eastern State Hospital in Lexington Nov. 20, 1947, aged 72, of hypostatic pneumonia.

Edward Orton Little, Indianapolis; State College of Physicians and Surgeons, Indianapolis, 1907; served during World War I; for many years affiliated with various Veterans Administration hospitals; died at his home in Danville, Ind., Nov. 18, 1947, aged 69, of adenocarcinoma of the gallbladder.

Ignazio B. Loncao, Brooklyn; Regia Università degli Studi di Palermo, Facoltà di Medicina e Chirurgia, Italy, 1897; died in Bethany Deaconess Hospital Nov. 21, 1947, aged 75.

Samuel McKee Lougeay • Belleville, Ill.; Barnes Medical College, St. Louis, 1899; veteran of the Spanish-American War; died Nov. 22, 1947, aged 77, of coronary occlusion.

Charles Allen McDonald • Columbus, Ohio; Chicago College of Medicine and Surgery, 1913; a medical officer during World War I; assistant medical examiner for the Pennsylvania Railroad; member of the Columbus Academy of Medicine; died Nov. 23, 1947, aged 62, of hypertension and diabetes mellitus.

Ray Thomas McDonald • Bridgton, Maine; Tufts College Medical School, Boston, 1918; member of the Massachusetts Medical Society; served as senior medical officer at Lawrence Memorial Hospital in Medford; died Dec. 5, 1947, aged 61, of coronary thrombosis.

John Quincy McDougald • Philadelphia; Leonard Medical School, Raleigh, 1897; affiliated with the Frederick Douglass Memorial Hospital; died recently, aged 78.

James Franklin MacGeagh, Detroit; Detroit College of Medicine, 1904; died recently, aged 76.

Edwin Robert McGrath, Cincinnati; Medical College of Ohio, Cincinnati, 1902; served during World War I; for many years district health officer; died in the Veterans Administration Hospital in Dayton recently, aged 67.

Donald Edward MacIntyre, Kimball, W. Va.; Hahnemann Medical College and Hospital of Philadelphia, 1941; interned at Homeopathic Hospital in Providence, R. I.; served during World War II; killed in an airplane accident at Ward, Nov. 9, 1947, aged 32.

William Chalmers Mount, Kirklint, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the American Medical Association; affiliated with the Clinton County Hospital, Frankfort; died Nov. 24, 1947, aged 68, of coronary occlusion.

Alfred Shelton Oliver Jr. • Imola, Calif.; Rush Medical College, Chicago, 1905; at one time medical superintendent of Eastern State Hospital at Medical Lake; affiliated with Napa State Hospital; specialist certified by the American Board of Psychiatry and Neurology; died Nov. 23, 1947, aged 66, of cerebral hemorrhage.

Antony Parsons • Valley, Neb.; John A. Creighton Medical College, Omaha, 1910; at one time a medical missionary in the Belgian Congo; for many years served on the school board; died Nov. 25, 1947, aged 70, of coronary disease.

William Parsons, Green Castle, Mo.; American Medical College, St. Louis, 1890; died Nov. 20, 1947, aged 85.

James Frank Paulin, Oak Park, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1894; died Nov. 13, 1947, aged 74, of chronic myocarditis.

Arthur A. Salvin • New York; Universität Zurich Medizinische Fakultät, Switzerland, 1911; fellow of the American College of Surgeons; affiliated with Sydenham Hospital, where he died Nov. 19, 1947, aged 66.

Emanuel John Senn, Chicago; Rush Medical College, Chicago, 1893; son of the late Dr. Nicholas Senn; member of the Chicago Surgical Society; formerly on the faculty of his alma mater as associate professor of surgery and the staff of Presbyterian Hospital; served during World War I; died Dec. 14, 1947, aged 78, of coronary occlusion.

Charles Edwin Spencer, Verona, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1907; served during World War I; died recently, aged 63, of pulmonary carcinoma.

Jack Harold Tritt, Fort William, Ontario, Canada; University of Toronto Faculty of Medicine, Toronto, 1940; resident physician at the Jewish Hospital in St. Louis; died suddenly, Nov. 18, 1947, aged 31.

Ralph Arthur Voigt, Hot Springs National Park, Ark.; St. Louis College of Physicians and Surgeons, 1918; died Nov. 8, 1947, aged 56.

Rome Maynard Webster, Dayton, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1907; member of the American Medical Association; on the consulting staff of the Miami Valley Hospital; died Nov. 25, 1947, aged 64, of carcinoma of the thyroid.

Carl W. Wilson, Fredonia, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1899; died recently, aged 77, of carcinoma.

Roy Alvin Zink • Tulsa, Okla.; Kansas City (Mo.) College of Medicine and Surgery, 1918; member of the staff of the Hillcrest Memorial Hospital; died Dec. 13, 1947, aged 53, as a result of accidental gunshot wounds incurred while cleaning a gun preparatory to a hunting expedition.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Jan. 28, 1948.

Collision With the Government Over the National Health Service

The stage seems fully set for a head-on collision of the British Medical Association with the government over the National Health Service Act. As shown in previous letters to *THE JOURNAL*, Mr. Bevan, the minister of health, has not made any concessions on the objections made by the representatives of the medical profession but has confined himself to offering modifications of the act if shown to be necessary in its working. The dominant objection is that the aim of the government is the nationalization of the practice of medicine and that the act is only a beginning of this process. The socialist government's avowed policy is nationalization of industries, and it has already accomplished this in the case of the Bank of England, the coal mines and the railways; it is preparing to nationalize the iron and steel industries. The government wants to nationalize the medical profession, but the physicians strongly object. Doctors do not want to lose their freedom and become state officials. They would lose even the right of medical publication, for a state official can publish nothing relating to his work without permission from his superiors.

The form of a plebiscite of 56,000 doctors of the British Medical Association on January 31 is in three sections:

1. "I approve/disapprove of the National Health Service Act in its present form.
2. "I am in favor/I am not in favor of accepting service under the Act in its present form.
3. "I agree to abide by the decision of the majority and undertake not to enter the service if the answers on question 2 reveal a majority against the undertaking as defined in paragraph 4 accompanying the plebiscite form." According to this, if the votes of consultants and specialists (not holding full time salaried posts) and general practitioners show a majority against accepting service under the act, and if the majority includes approximately 13,000 general practitioners of the estimated 20,500 (about two-thirds), the British Medical Association will advise its members not to enter into any contract under the act in its present form but to continue their service to patients and other professional work.

The correspondence columns of the *British Medical Journal* are full of letters against the act in its present form. In an editorial entitled "Why be Fearful?" readers are informed that the association has substantial funds to aid a doctor who votes against acceptance to overcome temporary difficulties. Dr. Dain, chairman of the council of the medical association, states that the act is directed toward the establishment of full time state medical service. The state will have a monopoly of all hospitals, and the private ownership of practices is to be abolished. The medical profession holds that a full time service will be harmful to medicine, and therefore to the public. The doctor can never give his best to the individual patient unless he feels that he has full responsibility for his own actions.

Censorship on Medical Publication Under the National Health Service Act

A surgeon of literary eminence, Mr. Johnston Abraham, has called attention in the *British Medical Journal* to the danger of government censorship of medical writings if doctors become servants of the state in the National Health Service. This

already exists in the Ministry of Education, under which no official is permitted to write educational books unless express permission has been given. In medicine such a situation would be disastrous, for articles or books criticizing official lines of treatment might be frowned on, held up or even suppressed. The danger pointed out by Mr. Abraham is confirmed by Mr. R. F. West, chairman of the medical group of the Publishers Association. He describes it as a matter of first importance, not merely to the medical profession but to the nation, that the doctor should be free to publish. In the House of Commons the question was asked: "What are the general principles under which state employees are allowed or forbidden for payment to write for publication on technical matters peculiar to their specialization?" To this the financial secretary to the treasury replied: "A Crown servant must obtain the consent of the head of his department for the publication of any work the subject matter of which is connected with his official duties or those of other public servants. In cases where the work is considered to owe its value exclusively to the author's ability and research, no special arrangements are made. In other cases the government may either arrange for official publication or stipulate that copies should be supplied for the public service at a special rate. These rules apply to the ministry of health. No rules have yet been made for employees under the ministry of health." This reply leaves the position of the doctor to be employed under the National Service Act somewhat obscure. If he is classified as a crown servant he will apparently seldom, if ever, be entirely free to write, and there is considerable danger that regulations will be laid down similar to those for other government employees. These would bring to an end the present freedom of expression of medical opinion.

Health of London Children Improved Despite War Shortages

Sir Allen Daley, medical officer and school medical officer of the London County Council, stated in his report for 1946, which has recently been published, that in spite of difficulties and shortages due to the war the school children of London had not suffered in health. Indeed, there was a higher percentage whose health was recorded as excellent—17.96 per cent in 1946 compared with 16.24 per cent in the prewar year of 1938—and a lower proportion of children was assessed by the school doctors to be in a state of subnormal nutrition—5.58 per cent subnormal and 0.04 per cent bad in 1946 compared to 6.50 and 0.06 per cent in 1938. Also there was a lower incidence in children of pathologic conditions of the ear, nose and throat and a smaller incidence of dental defects. In each age group there was in 1946 a higher proportion of children with normal eyesight. The reason for this improvement, which began with the war and has persisted, is not known. The incidence of cardiac defects in 1946 was half that recorded in 1938, and there appeared to be a decrease in the incidence of juvenile rheumatism. This report bears out the statement in a previous letter that the sensational attempts to suggest that the British people are being starved are unfounded. It is of interest that this improvement in the health of children runs parallel with a general improvement in vital statistics.

Traveling Professor of Surgery

Sir Hugh Cairns, Nuffield professor of surgery at Oxford, left England Dec. 23, 1947, for a three months' visit to Australia and New Zealand as the first Arthur Sims traveling professor. He will deliver lectures and take part in research and post-graduate teaching. It is also being arranged for him to visit the principal medical centers of South Africa next summer. It is confidently hoped that this traveling professorship will not only do much to stimulate the development of surgery but will also prove a further valuable link between the nations of the British Commonwealth.

RIO DE JANEIRO, Jan. 3, 1948.

Precipitin Reaction for the Diagnosis of American Trypanosomiasis

Dr. Julio Muniz, head, Division of Parasitology, Oswaldo Cruz Institute, has undertaken in the past three years experimental studies designed to improve the diagnosis of American trypanosomiasis. The last report of his work stresses the practical value of the simple technic of the precipitin reaction for the diagnosis of acute and subacute forms of the disease. In his first paper Dr. Muniz had reported that in human cases of American trypanosomiasis there is a great concentration of antibodies (amboceptor, agglutinins and precipitins), with a maximum during the acute stage and a progressive and steady decline with the passage to the chronic stage. This decline coincides with a definite diminution in the number of parasites in the blood stream. A similar study in rhesus monkeys experimentally infected revealed that a variable amount of those antibodies already existed in the incubation stage of the disease. The study included 255 human cases, 22 of which still were in the acute stage. Dr. Muniz' second paper reported the use, for the first time with protozoa, of the Fuller technic for the extraction of polysaccharides from bacteria. Using culture forms of *Tripanosoma cruzi*, he was able to extract a fraction that behaved as a good precipitinogen, which had a high holding power when employed as an antigen for the complement fixation reaction.

Dr. Muniz' last paper reports the results obtained in 21 new cases of the acute form of the disease, all from the county of Bambuhy, state of Minas Geraes, in addition to the 22 previously discussed. The extraction method was described in the first report (Muniz, J., and de Freitas, G.: *Mém. Inst. Oswaldo Cruz* 41:303, 1944). In its immunologic characteristics the American trypanosomiasis greatly differs from all other human diseases caused by protozoa, since in none of them has so strong a humoral immunity ever been demonstrated as the one presented by acute cases of trypanosomiasis. In all the 33 cases studied by Muniz the precipitin reaction was positive and was still fairly strong three and four months after the onset of the acute stage. This fact is important in diagnosis, particularly when one considers that American trypanosomiasis is a parasitic disease whose acute stage can evolve without pronounced symptoms and thus be unnoticed even by the patient himself. Another relevant point is the disproportion between the small number of cases diagnosed during the acute stage and the much larger number of those identified in the chronic stage through serologic reactions. The acute cases are diagnosed as a rule by direct demonstration of the parasites in the blood stream or by tiresome methods such as culture, inoculations and the xenodiagnostic test.

As a result of his careful study, Dr. Muniz emphasizes the following advantages of the precipitin reaction: (1) simple technic; (2) long lasting and stable precipitinogen; (3) small amount of serum needed for the reaction (0.1 cc. for the reaction tube and 0.1 cc. for the control tube); (4) immediate results, since most of the serums react within one or two minutes; (5) complete specificity, because, although the *T. cruzi* precipitinogen may react with immune serums prepared in rabbit with samples of the various species of *Leishmania* (as disclosed in the author's second report), this does not occur with serums from patients with cutaneous and visceral American leishmaniasis, owing to the low concentration of antibodies; (6) useful as an index of the degree of humoral immunity, because as a rule it occurs when the agglutination power of the serum is above 1:500; (7) useful as an index of the activity of the parasite, as is the case in the acute and subacute forms of the disease, since the humoral immunity is almost always well correlated with that activity, and (8) extremely useful in epidemiologic surveys, for the easy detection of active cases.

Treatment of Leprosy

The Sociedade Paulista de Leprologia has published the results of an extensive experiment on the treatment of leprosy by diaminodiphenylsulfone derivatives ("diasone" and "promin") performed by Drs. L. Souza Lima, G. Castro Cerqueira and Renato P. Braga at the Santo Angelo and the Padre Bento leprosariums of the São Paulo State Department of Health and involving more than 1,000 patients. The criteria to appraise the results were clinical, histopathologic and bacilloscopic.

From the clinical point of view, the authors stress that these drugs are well tolerated by patients with all forms of leprosy and of all ages, so that the treatment is without danger with a minimum of precautions. At the same time these agents are extremely active in the treatment of leprosy, although it is not yet possible to affirm how far this activity goes. The most important clinical facts are the almost immediate halting of the progressive evolution of the disease, with subsequent regression of the cutaneous manifestations and rapid involution of the mucosal involvement. The efficient and rapid action of the diaminodiphenylsulfone derivatives against the specific involvement of the bucco-naso-pharyngo-laryngeal mucosae, leading to dysphonia, aphonia and respiratory difficulties necessitating emergency tracheotomy, is sufficient evidence to commend the use of these drugs. The same conclusion is expressed by the authors in reference to specific lesions of the eyes, which may lead to complete blindness. From the histopathologic point of view the most important fact is the finding of tuberculoid structures in patients with lepromatous lesions who showed exacerbation of the cutaneous symptoms at the beginning of treatment. This seems to demonstrate a systemic participation in the regression of the process and a progressive degeneration of the initial lepromatous structures toward chronic inflammatory structures without a specific character in the patients who did not show the exacerbation. The structural changes found in biopsy specimens taken in different stages of the regressive process seem to point out the probable bacteriolytic action of the diaminodiphenylsulfone drugs on *Mycobacterium leprae*, either in histologic specimens or in smears, in the distinct stages of the treatment by diaminodiphenylsulfone compounds. Moreover, subsequent disappearance of the organisms in a great number of cases offers every probable proof of a bacteriostatic action of the drugs.

The authors say that the clinical evidence, the regression of cutaneous manifestations and the bacilloscopic findings in 93 per cent of the leprosy patients subjected to the treatment indicate that these drugs are, at present, the most efficient therapeutic resources for the treatment of leprosy persons.

Normal Protein Concentration in Blood

Drs. Luis C. Fonseca, Armando V. Rotondi and Francisco J. Schmidt, of the Paulista Medical School, São Paulo, have published the results of the determination of the total and fractional protein blood concentration in 110 men. The subjects were healthy young adults from 20 to 24 years of age, subjected to a standard diet containing at least 1 Gm. of protein per kilogram of body weight, 55 per cent of the proteins being of animal origin. The two great fractions of blood proteins—the albumins and the globulins—were determined by the refractometric method after Robertson, and the sum of the two fractions was taken as the total of proteins. The variation of the protein concentration was found to be as follows: Total proteins: average 78.3 Gm. per liter, standard deviation 5.2 Gm. per liter; albumins: average 56.9 Gm., standard deviation 6.3 Gm.; globulins: average 21.3 Gm., standard deviation 3.8 Gm.; ratio albumin: globulin: average 2.8, standard deviation 0.76.

Correspondence

HEPARINEMIA IN BLOOD DYSCRASIAS

To the Editor:—The studies of Drs. J. G. Allen, L. O. Jacobson and their associates at the Argonne National Laboratory on the mechanism of the hemorrhagic phases of thrombopenia, leukemia and radiation morbidity were the subject of recent editorial comment (*THE JOURNAL*, Dec. 27, 1947, p. 1156) but neither in the editorial nor in the publications cited was there mention of the significant pioneer work of M. Volkert and E. Hertel (*Ugeskr. f. læger* 31:781-786 [Aug. 5] 1943), who demonstrated the relationship of heparinemia to the hemorrhagic phases of the malignant hematologic dyscrasias, certain human atopies and certain instances of hepatopathy. The oversight was excusable, inasmuch as wartime inaccessibility of foreign periodicals and their abstracts led to an almost complete reduplication of Volkert and Hertel's work by the group with which I was associated at Halloran General Hospital before we were aware of it. In the latest report of the Chicago investigators (Allen, J. G.; Sanderson, M.; Milham, M.; Kirschon, A., and Jacobson, L. O.: *J. Exper. Med.* 87:71-85 [Jan.] 1948) on heparinemia, they interrogate the subject noun of their title.

With the hope of casting some light on the rather intricate relationship of heparinemia to a certain type of hemorrhagic diathesis I should like to outline the synthesis of a broad concept which has been previously elaborated but which has lain fallow in official files for almost two years. Its enunciation is not only justified because of the apparent confirmation rendered to the superb studies of Allen and associates but also for the possibility of the earlier general application of their results to a broad segment of the hematologic dyscrasias. About 40 per cent of patients with acute leukemia die solely as the result of what should now be a tractable form of hemorrhage: heparinemic extravasation.

Our own studies in this field (1) confirmed the probable identity with heparin of the anticoagulant described by Volkert and Hertel as well as by Allen and co-workers; (2) indicated that the additional factor whose absence from the blood in heparinemic extravasation was implied by both groups of investigators was probably the blood cholinesterases, and (3) permitted the nosologic unification of a set of apparently etiologically diverse conditions, among which may be incorporated the acute and terminal chronic leukoses, thrombopenic purpura, aplastic and agenic anemias, anaphylaxis and radiation morbidity and some instances of "dicumarol" intoxication, all of which have the propensity for culmination in heparinemic extravasation through a common pathodynamic modulus exactly comparable to that exhibited by laboratory animals subjected to peptone shock and which we termed the "atopic-exudative" syndrome (*Science* 104: 449 [Nov. 8] 1946). The elaboration of these points is as follows:

1. Volkert and Hertel concluded that the anticoagulant found in the blood of leukemic patients and subjects with pernicious anemia or allergies, like heparin, raised the antithrombic titers of such bloods. Allen and associates found that toluidine blue restored the coagulability to thrombopenic and leukotic bloods. Our own indication of the heparin-like nature of the anticoagulant in the blood of acute leukemic patients and those with allergic or thrombopenic purpura was based on the property of the plasmas of such bloods, like heparin, to dissociate the rates of precipitation of the agglutinative, the filar and the gelatinous components of normal plasma clot. Globin or human platelet

thromboplastin was found to restore the coagulability to heparinized blood or to the blood of persons in terminal stages of acute leukemia.

2. Invariably, when heparinemic extravasation occurred in any condition other than the therapeutic administration of heparin, it was accompanied by a demonstrable drop in the blood cholinesterase, particularly the erythrocytic fraction. Estrapenia (as this diminution is termed) without heparinemia is a common finding; the converse has not been encountered by us in any case of surgical or anaphylactic shock, overwhelming infection, aplastic anemia, agranulocytosis, leukemia, thrombopenic purpura, pemphigus or radiation morbidity.

3. The last enumerated conditions have as a common feature, in addition to heparinemic extravasation propensity, that they are all attended by temporary or protracted failure of erythropoiesis with consequent failure of erythrocyte cholinesterase production; many of their clinical features resemble intoxication by the known cholinergics, acetylcholine and histamine. Whether the fall in blood cholinesterase that likewise characterizes them is an accidental concomitant of this cholinergic intoxication or, as we believe, its determinant remains to be established.

ROBERT D. BARNARD, M.D.,
Laurelton, Long Island,
New York.

INTERNATIONAL MEDICAL SCHOOL

To the Editor:—In view of the development of a United Nations World Health Organization and a World Medical Organization, is not the next logical step the establishment of an International Medical School? To export medical knowledge by training foreign students could eventually save more lives than any other form of relief and would constitute one product of Western civilization whose moral value could not be questioned. Common humanity demands that we share this part of our security much as we are sharing our food.

The few foreign students graduating from our medical schools at present amount to only a trickle compared to the world need. Colonial medicine and the Rockefeller Foundation have attacked this problem and demonstrated what can be done. Medical missionaries like Seagrave and Schweitzer have publicized the opportunities of medical service in the tropics but lack civil authority and the possibility of perpetuating their efforts. Only a larger group of well trained indigenous medical graduates can assure the development of medical centers necessary to continued modern medical practice.

Could not the American Medical Association in cooperation with the World Health Organization explore the field and consider the feasibility of developing a medical school exclusively for foreign students in one of the larger cities, preferably in a warm climate? Certainly such a project should pay off in good will to say nothing of the creation of an international market for medical supplies which apparently only the western hemisphere will have the industrial equipment to produce.

And finally, in this air age knowledge of what diseases continue to exist in other parts of the world only a few hours away by plane has become important to us. So well have our armed forces advertised Western medicine around the earth that this should be one bill of goods that could be sold to those peoples and nations who must finance the undertaking and produce the students.

MERL G. COLVIN, M.D., Williamsport, Pa.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Testimony of Physician Based on Case History Given for Testimonial Rather Than Treatment Purposes.—The defendant was convicted in a bastardy proceeding and appealed to the Court of Appeals of Maryland.

The defendant contended that he was physically incapable of reproducing at the time of the alleged offense and argued, on appeal, that certain medical evidence offered by him had been improperly excluded. At the trial the defendant testified that he had had "a bad case" of gonorrhea about ten years prior thereto and that it had lasted about six months. He then testified that on the day of the trial he had submitted to a "sterilization examination and diagnosis" by a physician-pathologist and that he gave the physician his "full case history with respect to gonorrhea" and answered all the questions that were asked. With the exception of this testimony, there was no evidence as to what "case history" he gave the physician or what questions the physician asked him.

We think, said the court, that all questions to the physician relating to the defendant's "case history" were properly excluded. Medical testimony based on statements by "patients" who are not patients may be excluded. "It may be seen that, when attended by a physician for the purpose of treatment, there is a strong inducement for the patient to speak truly of his pains and sufferings, while it may be otherwise when medically examined for the purpose of creating evidence in his own behalf." The defendant, said the court, was not seeking treatment and cure at the time of the examination in question. In the case of a bona fide patient the physician may be better able than the patient to remember the material facts of the "case history." In the case at bar, however, said the court, the "case history" was ten years old and the defendant was examined by the physician on the day of the trial. There are many decisions, concluded the court, excluding such testimony.

Because of the exclusion of certain medical testimony not relating to the "case history," however, the judgment of conviction was reversed and the case remanded for a new trial.—*Parker v. State*, 55 A. (2d) 784 (Md., 1947).

Narcotic Violations: Statute of Limitations and Sufficiency of Evidence.—The defendant was convicted for two violations of narcotics laws. He accordingly appealed to the circuit court of appeals, eighth circuit.

The defendant was a physician practicing in a small Arkansas town of 600 to 800 inhabitants. He filled his own prescriptions and had duly paid the special tax and made the registration necessary for dispensing or administering narcotics medicinally. One of the counts on which he was found guilty charged that he had sold to persons, in quantities unknown, a specified gross amount of morphine sulfate cubes, morphine sulfate tablets and tincture of opium, not in good faith, not in the course of his professional practice and not in pursuance of the written orders of such persons on the required form. The other count charged that between certain dates the defendant, by means of forms issued by the government for that purpose, obtained certain drugs for purposes other than the use, sale or distribution by him in the conduct of a lawful business in said drugs or in the legitimate practice of his profession.

The first question for determination was whether any of the illegal sales charged in these two counts were barred by the statute of limitations. The indictment was returned on Sept. 9, 1946. It charged offenses extending from June 21, 1943 to May 10, 1945. Illegal sales of narcotics, or uses of order forms to obtain narcotics for unlawful purposes, are subject to the general three year statute of limitations provided for in the Internal Revenue Code. Each separate sale of narcotics or each separate use of an order form to obtain narcotics, unlawfully made, is a distinct offense under the statute. Such sales or

uses of order forms, though multiplied, do not constitute a continuous offense, for the narcotics act does not create the offense of engaging in the business of selling the forbidden drugs but only penalizes sales made in the absence of the qualifying requirements. We therefore think that the trial court erred, said the circuit court of appeals, in allowing the jury to consider and return a verdict on the basis of any illegal sales or any illegal uses of order forms which had occurred prior to Sept. 10, 1943, the start of the three year period.

The defendant also contended that certain other evidence was erroneously admitted. A witness from one of the largest pharmaceutical houses in the country was permitted to testify that the number of morphine tablets purchased by the average physician was from two hundred to five hundred $\frac{1}{4}$ -grain (15 mg.) tablets per year. A physician with a general country practice in a locality in Arkansas comparable to that in which defendant resided, who detailed the nature and extent of his practice, was permitted to testify to the amount of morphine tablets which it was necessary for him to purchase in his practice during the period covered by the indictment. Similar testimony by a number of other representative physicians in the state was admitted, some of whom filled their own prescriptions and some of whom did not, but all of whom sufficiently detailed the nature of their practice and the uses they made of the drug to afford the jury a fair opportunity for comparison. One of the physicians who did not fill his own prescriptions testified in effect that substantially all his prescriptions were taken to and filled by a certain druggist, and this druggist was permitted to testify to the number of the doctor's narcotic prescriptions during the period. A pharmacist from a drug store serving approximately ten thousand persons was permitted to testify that the ratio of general medical prescriptions in the store to prescriptions containing narcotics ran 9 to 1.

We think, said the court, that all this evidence was competent and of probative value. During the period covered by the indictment, the defendant was shown to have bought narcotics equivalent to a total of 45,708 $\frac{1}{4}$ -grain (15 mg.) doses of morphine sulfate, which would have enabled him to dispense or administer narcotics in that time equivalent to more than 69 $\frac{1}{4}$ -grain (15 mg.) doses of morphine sulfate per day. There was evidence that the ordinary dose of morphine sulfate was $\frac{1}{4}$ -grain (15 mg.). In the technical field involved it was proper to admit evidence from which the significance of the various figures brought out during the trial could be evaluated by the jury through practical, relevant and fair comparisons. Such evidence as is referred to in the foregoing statement has been recognized as proper in a number of narcotics cases.

Complaint was also made of other evidence admitted by the trial court. A physician was permitted to answer the following question: "In your opinion, can a reputable physician in a town of several hundred people dispense and administer in a period of twenty-three months, in the course of a bona fide practice only, as much as 35,000 $\frac{1}{4}$ -grain (15 mg.) tablets of morphine sulfate?" This question was fundamentally objectionable, said the court of appeals, as an attempt to get before the jury the fact, even though not in express terms, that in the opinion of the witness the defendant was guilty. The purpose and effect of the question was to have the physician, with his professional prestige, advise the jury that he thought a physician who ordered and used that much narcotics within the period involved was making an illegal disposition of the drugs. There was no reason to allow the witness to express his opinion on the question asked, either as a matter of lack of other proof of the fact involved or as a necessary aid in understanding such other proof, and the admission of the opinion as evidence was in the opinion of the court prejudicial.

Finally, witnesses from different wholesale drug companies, from which defendant had purchased narcotics, were permitted to testify that, if the company which the particular witness represented had received orders from the defendant for all the narcotics which he purchased, it would not have filled the orders. The question was improper, said the court. It was directed specifically to what those particular drug companies would have done in the defendant's case, not to a general trade

practice, and so merely served the purpose of pointing the finger at the defendant rather than of indicating any general fact.

Because of errors in the admission of evidence and because of the bar of the statute of limitations with reference to some of the offenses testified to, the judgment of the trial court was reversed and the case was remanded for a new trial.—*Hesson v. United States*, 161 F. (2d) 50 (1947).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in *THE JOURNAL*, Feb. 14, page 491.

•BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination*, Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ALASKA: * *Examination*, Juneau, March 2. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: * *Examination*, Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Electric*, Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral*, San Francisco, June 5-6; Los Angeles, Feb. 28-29. *Written Examination*, Los Angeles, March 1-4. *Oral and Clinical Examination for Foreign Graduates*, Los Angeles, Feb. 29; San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

COLORADO: * *Examination*, Denver, June 21-23. Final date for filing application is June 5. *Endorsement*, Denver, April 6. Final date for filing application is March 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * *Examination*, March 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homopathic Examination*, Derby, March 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity*, Washington, D. C., March 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 E Municipal Bldg., Washington.

FLORIDA: * *Examination*, Jacksonville, June 29-30. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

INDIANA: * *Examination*, Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

IOWA: * *Examination*, Iowa City, March 15-17. Comm., Dr. Walter L. Biering, Dept. of Health, Des Moines.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination*, Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical Examination*, Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homopathic Examination*, Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination*, Boston, March 9-12. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

MISSISSIPPI: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: *Examination*, St. Louis, May 24-26. Final date for filing application is April 24. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA: * *Examination*, Omaha, April 12-14. Dir., Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln 9.

NEVADA: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: *Examination*, Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination*, Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NORTH CAROLINA: * *Endorsement*, Pinehurst, May 4. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OHIO: *Endorsement*, Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

OKLAHOMA: * Oklahoma City, June 2-3. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: * *Endorsement*, Portland, May 7-8. Final date for filing application is April 23. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

RHODE ISLAND: * *Examination*, Providence, April 1-2. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Written Examination*, Columbia, June 21-23. *Endorsement*, March 1. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

UTAH: *Examination*, Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: *Examination*, Richmond, June 18-19. *Endorsement*, Richmond, June 17. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 23-29. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: *Examination*, Tucson, March 16. Sec., Mr. Francis A. Roy, Science Hall, Univ. of Arizona, Tucson.

ARKANSAS: Little Rock, May 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

DISTRICT OF COLUMBIA: *Examination*, Washington, April 19-20. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington.

FLORIDA: *Examination*, June 5. Final date for filing application is May 23. Sec., Mr. M. W. Emmel, Univ. of Florida, Gainesville.

IOWA: Des Moines, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination*, Ann Arbor and Detroit, May 14-15. Sec., Miss Eloise Lefebvre, 101 N. Walnut St., Lansing 15.

MINNESOTA: *Examination*, Minneapolis, April 6-7. Sec., Dr. Raymond N. Dieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

OKLAHOMA: Oklahoma City, April 2. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination*, Portland, June 19. Sec., Basic Science Examining Committee, Mr. C. D. Byrne, Univ. of Oregon, Eugene.

SOUTH DAKOTA: *Examination*, Vermillion, June 4-5. Sec., Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, March 15-16. Sec., Dr. O. W. Hyman, Univ. of Tennessee, 874 Union Ave., Memphis.

WISCONSIN: *Examination*, Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Medical Motion Pictures

FILM REVIEWS

Ascorbic Acid and Scurvy. 16 mm., black and white, sound, 900 feet (one reel), showing time twenty-one minutes. Prepared in 1947 by Frederick F. Tisdall, M.D., Assistant Professor of Pediatrics, Faculty of Medicine, University of Toronto, Toronto, Canada. Produced by and procurable on loan from: Mead Johnson & Company, Evansville, Ind.

This lecture film presents ascorbic acid and its relation to scurvy. It depicts the history, physical signs, symptoms, diagnosis and treatment of scurvy. Clinical photographs and roentgenograms are used to illustrate a few typical case reports.

Of particular interest and value is the discussion of charts showing the ascorbic acid content of various foods and how the ascorbic acid content is influenced by various methods of storage, handling and cooking. The narrator's voice is clear and the photography is excellent.

This film is recommended for pediatricians because of their special interest both in the subject and the author, a distinguished member of their group, to general practitioners, medical students and dietitians.

The Miracle of Living. 16 mm., black and white, sound, 1,400 feet, (one reel), showing time thirty-eight minutes. Prepared and produced in 1947 by the Medical Department, United States Army, Washington, D. C. Procurable on loan from the War Department, U. S. Army, Office of the Surgeon General, the Pentagon Building, Washington, D. C., or the Army Surgeons Headquarters in your local area.

This film drives home the fact that even experienced and sophisticated young persons may become infected with gonorrhea; that treatment of gonorrhea with penicillin may still leave the person infective, and that promiscuous sexual intercourse is still a serious hazard to normal marital happiness.

The idealism of the engaged couple regarding love, marriage and having a family is well depicted without undue sentimentality. The girl shows loyalty to her fiancé while he is overseas and such complete trust in his integrity that the observer sympathizes with her when, disillusioned, she insists on divorce.

The subject, though delicate, is skilfully handled and should be acceptable for either segregated or mixed audiences of high school age.

This film, though made for the Army, should prove to be an important addition to the health teaching films for use in high schools, colleges, public health departments and voluntary health agencies.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Manifestations of Multiple Sclerosis. B. W. Lichtenstein.—p. 197.

Sclerosis.—According to Lichtenstein there is no question either the cause or the cure of multiple sclerosis. Five years fever therapy with typhoid-paratyphoid vaccine mechanically induced fever were in vogue. At a later date quinine sulfate was used rather extensively. Since the advent of vitamin B and particularly thiamine chloride, untold quantities have been poured into patients with multiple sclerosis. Of late the histamine and "dicumarol" treatments have become fashionable. In Lichtenstein's opinion the acute attack with excessive fatigue should be treated with rest, eradication of foci of infection and adequate diet. The prognosis in multiple sclerosis is not as grave as many believe. Some persons have two or more mild attacks and never go on to development of the advanced form of the disease. Others continue to have recurrent attacks with severe involvement of the nervous system followed by permanent defects.

Ligation of Inferior Vena Cava.—Ray and Burch describe observations on 12 women in whom the inferior vena cava was ligated for pelvic thrombophlebitis. They were studied for as long as four and one-half years. After ligation of the inferior vena cava the pressure in the dorsal pedal veins was greatly elevated in all but 1 patient. A gradual fall in venous pressure occurred with time. The pressures in the antecubital veins were normal. Five of 6 patients studied had an elevated venous pressure in the superficial abdominal veins. The volume of pulse deflections in the tips of the toes was reduced immediately

after operation. Section of the sympathetic nerves resulted in a greater mean value immediately after operation. Five patients had a normal rate of water loss from the fingertips, volar surface of the forearm, pretibial area and tips of the toes in a comfortable environment, and the rate increased normally in response to a hot and humid environment. The plasma protein levels tend to be slightly higher than normal. After ligation of the inferior vena cava, tissue pressure in the pretibial areas rose. Tissue pressure tended to vary directly with the venous pressure and inversely with the degree of the edema. Clinical observations revealed normal function of the lower extremities and normal texture, temperature, color and response to sensation of the skin. The veins of the feet and legs were small; varicosities were limited to minute veins of the skin. The abdominal veins were dilated, and the blood flow was cephalad. Edema occurred in all but 2 patients and disappeared early in convalescence in all except 2, in whom the edema was present for eight months. Clinical and physiologic observations failed to reveal any detrimental effect from ligation of the inferior vena cava. The circulatory adjustments were adequate, although not all the compensatory mechanisms are clearly understood.

Thrombosis of Hepatic Veins.—Thompson reports 2 cases of thrombosis of hepatic veins and reviews 95 from the literature. In the majority of reported cases there was gross obstruction of hepatic veins, leading to engorgement and necrosis of the liver and to portal obstruction. In some instances the block occurred as a final episode in an already advanced disease which itself masked the characteristic clinical picture of the Chiari syndrome. There were cases in which the obstruction was limited to one lobe or to part of a lobe. While there is a pathologic unity which may be expressed by referring to all cases as examples of thrombosis of the hepatic veins, it is considered that descriptive separation is necessary. It is proposed that the name Chiari, or Budd-Chiari, syndrome should be retained for cases in which there is gross blockage of the hepatic veins and that cases with more limited lesions, not giving the full picture, should be referred to as cases of thrombosis of the hepatic veins. The syndrome of thrombosis of the hepatic veins may be due to a variety of disease processes. There may be a general disease, such as polycythemia, carrying a pronounced tendency to thrombosis, which in combination with a minor local lesion will cause thrombosis of the hepatic veins. Conversely, there may be a gross local lesion with a minimal general disease. The general causes of the syndrome include conditions in which there is a tendency toward thrombosis. Pain is usually the initial symptom. Ascites, hepatic and splenic enlargement, edema of the legs, jaundice and vomiting are other symptoms. In the majority of cases the disease is of short duration, in some lasting only a few days. In the smaller group the disease may last from ten to twenty-eight years. The treatment of this disease must be on the same lines as the treatment for portal cirrhosis. Of the 2 cases described in detail, the first shows the result of repeated thromboses over a long period. In the second case the thrombosis probably commenced about the ostia of the hepatic veins and spread to the cava and to the hepatic veins proper. Support for the theory of a general vascular disease was given by the renal infarct, the nature of which suggested a venous thrombosis as the cause, and by the vascular lesion in the myocardium. Diagnosis of this condition should be kept in mind in cases of obscure pain in the upper part of the abdominal area, especially when there is any evidence of hepatic damage.

Peritoneal Lavage in Acute Uremia.—According to Bassett and his associates equilibrium between crystalloids of the interstitial fluids is established rapidly when various isotonic or mildly hypertonic and hypotonic fluids are injected into the abdomen. For this reason, lavage of the peritoneum has been performed in an attempt to relieve the intoxication of uremia. Although so far only 2 survivals have been reported with this vividialysis, the authors believe that with a better selection of cases better results may be anticipated. They report the case of a woman, aged 24, in whom peritoneal irrigation was carried on continuously for twenty-one days. She had subacute

glomerulonephritis and became almost completely anuric two days before the irrigation was started. Flow of urine was not reestablished, and the patient died. The total nitrogen removed by way of the peritoneal cavity was 257.8 Gm. Of this amount, 140.8 Gm. was nonprotein nitrogen and 117 Gm. protein nitrogen. The former was fractionated into urea and ammonia nitrogen 110.3 Gm. and undetermined nitrogen 30.5 Gm. Substantial reductions in the concentration of blood nonprotein nitrogen and serum inorganic phosphorus were obtained at first, but as the patient lost edema fluid these values rose above the pretreatment levels. This is thought to have been due to a more rapid loss of water than of nonprotein nitrogen from the body, rather than to an increase in nitrogen catabolism. Bicarbonate in the plasma increased from 25 to 60 volumes per cent because of the administration of sodium lactate solution intravenously and the withdrawal of chloride in excess of base from the stomach.

Cystic Disease of the Lung.—McRae reports 4 cases of congenital cystic disease of the lung in three young men aged 20, 19 and 18 years, respectively, and in a boy aged 12; the 4 patients were brothers and members of a French-Canadian family of eleven children. The family history was negative. A review of the literature indicates that these 4 cases are unique in their familial incidence, in the presence of decided clubbing of fingers and toes without pulmonary sepsis and in the malignant nature of the disease, which resulted in the death of all 4 patients before adult life was reached. In all other characteristics they conform to the general picture of the alveolar type of congenital cystic disease. Diagnosis on clinical features failed in all cases, although there was no masking of the basic characteristics. The diagnosis was established on necropsy. Erroneous diagnosis of tuberculosis was made in 2 of the cases. Diagnosis of tuberculosis must be questioned unless it is confirmed by microscopic section or bacillary findings.

Postoperative Wound Disruption.—Trueman reports from the Winnipeg General Hospital 18 laparotomies requiring resuture of disrupted wounds. Six deaths could be attributed directly or indirectly to this incident. The majority of the cases represented major surgical problems. Intervention was performed on patients in whom it was impossible to obtain an optimum surgical state. The age of the patients varied from

that of an infant 3 days old to adults who were advanced in life. The time of occurrence of the incident was as early as three days and as late as thirty-nine days after the operation. Peritonitis was present in only 1 case. There can be no doubt, since most wound disruptions occur in the upper portion of the abdomen, that the strong lateral pull produced by the costal margins because of abnormal respiration and coughing is a factor. Protein deficiency is sufficiently important to justify a proper program of treatment to correct it prior to undertaking major surgical procedure. In the face of shock and malnutrition secondary closure is a formidable proposition. No patient should be treated without preliminary sedation. In certain cases where resuturing might obviously spell disaster the coaptation of the skin edges by adhesive tape is a worth while measure. Penicillin should be administered routinely for at least forty-eight hours. Decompression of the stomach should be maintained by use of a nasal catheter. Blood transfusions, plasma and parenteral amino acids may be employed to maintain the patient's nutrition and improve his healing powers. Large doses of ascorbic acid should be given.

Miniature Chest X-Rays.—According to Fralick and his co-workers, photofluorography compares favorably in sensitivity with 14 by 17 inch (35.56 by 43.18 cm.) roentgenograms for screening purposes. Routine roentgen examinations of the chest will not necessarily reveal evidence of certain nontuberculous diseases and will not forecast the subsequent development of pulmonary tuberculosis in those who are classified as negative on a single examination. In the authors' experience 2 per cent of those receiving miniature roentgenograms of the chest required further examination for possible tuberculous disease. Approximately 30 per cent of that group proved to be without demonstrable disease. The percentage recalled for further examination and to some extent the amount of "over-reading" from the miniature films will be greatest when interpretation is overcautious, when any clothing remains on the chest, when films are technically substandard and when the older age groups are being screened. Among 126,089 miniature chest x-rays taken in 1946 by the Gage Institute Chest Clinic in Toronto, 0.91 per cent disclosed tuberculous disease (0.11 per cent active) as confirmed by clinical examination; 0.61 per cent exhibited evidence of significant nontuberculous diseases or abnormalities; 1.9 per cent manifested less significant abnormalities such as previous pleurisy or pulmonary calcifications; 96.4 per cent showed no demonstrable disease. As long as this method continues to disclose a significant number of persons with asymptomatic active and inactive pulmonary tuberculosis, its adoption and the examination of contacts so revealed will constitute a useful addition to the already existing facilities for the control of tuberculosis.

Multiple Segmental Resection.—Overholt and his co-workers performed 53 segmental resections in 39 patients with bronchiectasis. There was 1 fatal case, but the death was not related to the type of resection performed. Bronchiectasis is usually segmental rather than lobar. Surgical treatment should remove all the involved segments without sacrificing any normal pulmonary tissue. Refinements and advances in diagnosis, localization and surgical treatment now make such a goal attainable. All the authors' patients had at least two segments, or a lobe and a segment, excised under procaine anesthesia

with endotracheal intubation under cocaine topical anesthesia and with the patient in the face-down position to obviate the risk of contralateral flow of secretions during intervention. An uneventful postoperative course is largely dependent on the maintenance of a free airway and prompt, complete pulmonary expansion. Bilateral operations have been completed in 14 of 26 patients with bilateral bronchiectasis. As a group they are strikingly better than the patients with bilateral disease treated by bilobar or trilobar resection. Segmental resection is especially applicable to patients with multilobular involvement in whom conservation of all normal pulmonary tissue is essential.

Perineal Prostatectomy for Cancer.—Goodyear thinks that the perineal approach to the prostate has been unjustly neglected. He believes that the great fear of incontinence and fistulas is without foundation. It is the only method by which carcinoma of the prostate can be removed. Studies show a 15 per cent incidence of carcinoma of the prostate in men above the age of 45. It occurs both with and without hyperplasia, and the importance of rectal examination in men of this age group cannot be overemphasized. The perineal operation is the most direct approach to the prostate. The operation entails little shock and is well tolerated. Mortality statistics are uniformly lower than in suprapubic operations. Postoperative drainage is excellent, lowering morbidity by prevention of sepsis from stasis. The wounds heal by primary union. Confinement in bed, the period of catheter drainage and the hospital stay are materially shortened. Analysis of the functional results of perineal prostatectomy reveals that they compare favorably with suprapubic and transurethral operations. Actually the three cannot be too strictly compared, for their indications are so different that they cannot be rationally applied to all types of cases. Perineal prostatectomy is the method of choice not only in cancer of the prostate but also in many benign conditions such as hyperplasia, calculosis and fibrosis.

"Pyribenzamine" in Hay Fever.—Fuchs and his co-workers treated 112 patients who had hay fever with injections of ragweed pollen extract to one group of 40 patients; twenty-one tablets a week of 50 mg. of tripeleannamine hydrochloride ("pyribenzamine hydrochloride" N.N.R.), one tablet after each meal three times a day, to a second group of 40 patients, and one 50 mg. tablet of tripeleannamine twenty minutes before all ragweed pollen extract injections to a third group of 32 patients. The results following treatment of each group were tabulated on the basis of the percentage of treated patients who manifested certain symptoms for a forty-two day period from August 10 to September 20. No significant difference was noted in the percentage of patients who experienced no or slight symptoms of hay fever in the three groups. An estimation of the percentage of patients who had moderate or severe symptoms showed that those who took tripeleannamine alone had slightly more symptoms of hay fever than those in the other two groups. The temporary symptomatic relief given by the drug was proportionate to the dosage prescribed. Tripeleannamine does not immunize or protect the patient with hay fever from the effects of the antigen-antibody reaction for any length of time. The mode of action of the drug is still unknown. There is no definite proof that all allergic manifestations are the result of histamine activity. Administration of the drug prior to the injection of pollen extract made possible greater increases in the dosage of the pollen extract, and the patients were able to reach a maximum dosage almost double the amount they usually tolerated when taking the pollen extract alone. "Pyribenzamine" is a valuable drug for the symptomatic relief of hay fever symptoms.

Autonomic Nervous System.—Cohen and Wolf compared the incidence of increased palmar sweating in 63 patients with allergic respiratory disease with that of 63 psychoneurotic patients in order to assess the psychiatric factor in palmar sweating. They compared the incidence of palmar sweating in the allergic patients with that in 99 syphilitic patients because the latter presented an analogous situation in the clinic to the first, with both groups anticipating parenteral medication. All patients were between the ages of 15 and 65 years. The patients with allergic respiratory disease manifested a statistically significant increase in the incidence of intense palmar sweating as determined by the Silverman technic over the patients with psychoneurosis and syphilis. Race, sex and age are without influence on intense palmar sweating. The difference in incidence between the allergic and nonallergic groups is due to factors associated with the clinically manifest allergic state and are not sampling errors. Sweat glands are supplied by fibers of the sympathetic nervous system, but functionally they are cholinergic. Palmar sweating bears no relation to water loss from other parts of the skin or respiratory tract.

It is suggested that clinically manifest allergic respiratory disease in man is dependent on an inherent behavior pattern of the autonomic nervous system in addition to the immunologic factor of hypersensitivity.

"Benadryl" and "Pyribenzamine" in Reactions to Penicillin.—Dreishach's animal experiments showed that repeated optimum daily doses of diphenhydramine ("benadryl") or tripeleminamine ("pyribenzamine") given subcutaneously were ineffective in preventing the development of the Arthus type of skin sensitivity reactions to penicillin or horse serum in rabbits. Diphenhydramine or tripeleminamine mixed with penicillin and injected subcutaneously likewise did not prevent the sensitivity reactions. However, either of the drugs mixed with histamine prevented the typical skin reactions of histamine in scratch tests on rabbit and human skins. The negative objective experimental results obtained with these antihistaminic agents suggest that the nature of relief with these agents in clinical reactions to penicillin, and possible other allergic reactions, is also not objective but essentially subjective and presumably related to the central and peripheral sensory depression of these agents.

Thymol Turbidity Test in Liver Disease.—Experiments by Kunkel and Hoagland with serums selected from a group of 200 patients with infectious hepatitis admitted to the outpatient department of the Hospital of the Rockefeller Institute demonstrated that the turbidity produced by the thymol reagent of Maclagan in these serums depends on the presence both of lipids and of abnormal lipid protein complexes migrating in the beta globulin fraction of the serum. The gamma globulin fraction of serum also plays an important role in the reaction. The relative importance of the different components in the reaction varies with different serums. Development of turbidity is prevented if the lipids are kept in solution by the addition of a "tween" or are extracted with ether, or if the gamma globulin is removed. In lipemic serums the thymol reagent causes a nonspecific increase in the turbidity due to increase in particle size of the lipid globules. Correction for this effect can be made by using a photometric blank prepared from serum and a thymol reagent containing such a high buffer concentration that precipitation of the globulin component is prevented. Immunologic experiments on rabbits did not reveal evidence that the protein concerned in the reaction was abnormal. In patients with acute infectious hepatitis values for the thymol turbidity test were found to parallel alterations in serum lipids initially and alterations in gamma globulin during late convalescence.

Temporary Cessation of Renal Blood Flow.—Koletsky and Gustafson produced complete renal ischemia in white male rats under anesthesia with intraperitoneal sodium pentobarbital by occluding the renal artery and vein with clamps for thirty minutes, one hour, ninety minutes and two hours. The animals survived the thirty minute period and usually the one hour period. The mortality at ninety minutes was 73 per cent, and at two hours the procedure was uniformly fatal. After circulation was restored by removal of the clamps, the blood urea nitrogen level rose rapidly until death, or reached a maximum level and then declined with survival of the animal. The principal morphologic change was necrosis of the descending segments of the proximal convoluted tubules. The renal lesion was not similar to that observed in human or experimental crush syndrome or in rats with fatal tourniquet shock.

Intranasal Inactive Influenza Virus.—Quilligan and Francis administered intranasal sprays of equal parts of type A and type B influenza virus, inactivated with solution of formaldehyde and diluted (1:5) in isotonic sodium chloride solution, to 40 of 80 boys between the ages of 8 to 14 years at the Wayne County Training School in Northville, Mich. Twenty boys were given a 1:40 dilution subcutaneously, and the remaining 20 boys received 1 intranasal inhalation of sterile normal fluid. An additional 70 boys were not vaccinated and did not receive any control fluid. A single intranasal inhalation of the inactivated influenza virus preparation resulted in good antibody responses, and the use of five daily sprays gave slightly higher levels of antibody. A comparison of the effect of the two different doses of intranasal vaccine on the serums taken five months after vaccination suggests that the larger dose gave a more persistent elevation in antibody titer. The vaccine given intranasally on five successive days contained approximately eight times as much inactive virus preparation as the subcutaneous material. Comparison of the antibody responses indicates that subcutaneously administered vaccine gives higher and more persistent levels with smaller doses. Clinical observations were made during an epidemic of influenza B in the institution in December 1945 after the vaccination performed in October 1945. Eight of 58 children in the three vaccinated groups developed clinical evidence of disease. In 29 of the 89 unvaccinated children there developed clinical evidence of influenza, including 4 children from the inhalation control group. No significant evaluation of the effects of administration of the virus materials on the incidence of infection with influenza could be made.

Nutritional Deficiency and Hypogonadism.—Biskind shows that impaired hepatic function on a nutritional basis leads to alteration of the estrogen-androgen equilibrium, owing to failure of the liver to inactivate estrogen in deficiency of the B vitamins, while it continues to inactivate androgen. The author found that of 143 patients with nutritional deficiency, ranging in age from 29 to 61, impairment of libido and potency of which the patient was aware occurred in 96. The incidence of this disorder in B avitaminosis is probably higher. Testicular atrophy occurred in 67. Glossitis, hepatomegaly and testicular atrophy appeared simultaneously in 58. Of 76 patients who were followed subsequently, nutritional therapy alone led to subsidence of the avitaminotic lesions and definite improvement in libido and potency in 62. Psychogenic factors were undoubtedly operative in several of the failures. The frequent association of lesions of nutritional deficiency, especially glossitis, with hepatomegaly and testicular atrophy suggests that the presence of any one of these lesions should lead to search for the others.

The author stresses the multiplicity of deficiencies and states that desiccated liver, being unfractionated, provides probably the best available source of the as yet unidentified factors essential to nutrition, although some slight losses probably occur from drying and oxidation. It must be given in relatively large doses to be effective. All the products are given in divided doses after meals. A number of severely deficient patients require parenteral therapy in addition.

Results in Tantalum Cranioplasty.—A survey by questionnaire of veterans' hospitals revealed that a total of 49 tantalum plates were removed. In an additional 7 cases associated abscesses or collections of exudate under the scalp were treated by aspiration or drainage, and removal of the plate was not required. The factor common to practically every case in which the plate was removed was the presence of persistent infection, associated in some cases with osteomyelitis involving the bone edge. The infection was usually a delayed reaction occurring from four to twenty-two months after the insertion

of the plate. Three additional plates have been removed at the veterans' hospital at Dearborn, Mich. When infection of the cranioplasty has occurred, conservative measures have always failed. A continuing recurrence of infection has finally required removal of the plate.

Febrile Convulsions.—Livingston and his co-workers studied 94 patients, each of whose first convulsion in childhood was associated with an acute febrile illness. In 18 of the 94 patients not only the initial but each subsequent convulsion was accompanied by fever; all 18 patients recovered. Seventy-six patients had both febrile and afebrile convulsions, and only 28 of them recovered. The earliest age of cessation of febrile convulsions in this series was 3½ years; the latest age was 8 years. The earliest age of onset was 3 months; the latest 8½ years. Age of onset, sex, race and form of anticonvulsive treatment did not seem to influence the final outcome. The prognosis for recovery in patients whose convulsions were invariably associated with fever was good. The prognosis was better for those patients who had fewer recurrent attacks. Focal convulsions carried more serious prognostic importance than generalized convulsions. There is a relatively less favorable prognosis for a convulsive child whose close relatives have suffered from chronic epilepsy, whereas the outcome is better if only childhood convulsions have occurred in close relatives. It is suggested that there may be a significant difference between the hereditary factors which predispose to chronic epilepsy and those which predispose to childhood convulsions. Patients with a negative family history showed less tendency to recover than those with a family history of childhood convulsions.

Mumps Meningoencephalitis.—Eberlein and Lynxwiler describe the clinical picture of mumps meningoencephalitis based on 280 cases from the literature. Two hundred and sixty-six (95 per cent) of the patients complained of headache, usually frontal. Approximately 80 per cent had nausea and vomiting. If the patient was a child, the parents often remarked that he had been lethargic or the somnolence was noted later in the disease. Thirty-one patients (11 per cent) had convulsions and 48 (17 per cent) were disoriented and unable to give a history. The patients were running a temperature, usually between 100 and 102 F. There were variable degrees of meningeal irritation and nuchal rigidity or abnormal reflexes such as positive Kernig or Babinsky signs. All of these, like the parotitis, may be absent at first only to appear later in the disease. In all except 33 of the cases the diagnosis was based on the typical clinical picture appearing either during an epidemic of mumps or in persons with a definite history of exposure to mumps. In 1 case of mumps meningoencephalitis without parotitis in a boy aged 9 there was no epidemic or history of exposure to mumps to suggest the true diagnosis. The patient's sister, aged 10, was admitted to the hospital ten days later with a dull pain beneath the lobe of the left ear and with a temperature of 101.6 F. The fever lasted four days, after which she had no symptoms. Both the boy and his sister, five to six weeks after their recovery, had high complement fixation titers for the mumps virus. Fifteen days after the onset of the boy's illness the mother of

these 2 children, who nursed the boy throughout his illness, had a full-blown bilateral parotitis. It is suggested that meningo-encephalitis without parotitis is infectious and that complement fixation test may be the only way to establish the diagnosis.

Premature Closure of Cranial Sutures.—Simmons and Peyton operated on 5 patients with craniostenosis, 3 male children between the ages of 8 months and 3½ years and 2 women aged 28 and 29 years, respectively. Craniostenosis is an anomaly in which the sutures of the skull close prematurely, causing compression of the intracranial contents. Microcephaly gives most difficulty in the differential diagnosis of craniostenosis. In the large majority of cases it should be possible to distinguish between these two conditions at an early age. Mental retardation, one of the earliest symptoms of craniostenosis, is the most important indication for surgical intervention and one which has received little emphasis in the past. It is impossible to repair damage which has already occurred to the brain, but further damage may be prevented by early craniectomy. Blindness is one of the commonest symptoms, and surgical intervention should be performed at the first indication of failing vision. Occasionally surgery may be necessary for the relief of severe and persistent headaches which may be associated with the disease. Because the bones of the skull in infants are thin and flexible, linear craniectomy will allow for adequate expansion of the brain and will allow the head to assume a normal shape. After linear craniectomy the bone tends to form bridges across the artificial suture lines and to arrest expansion; this is probably one of the reasons for poor results following surgical intervention in these cases. Tantalum foil interposed between the bone edges should prevent this regeneration and should allow continued expansion of the skull without additional operations. This method was employed in 2 of the authors' patients aged less than 1 year. One year after operation psychometric testing revealed that one of these patients had an intelligence quotient of 100, and he seemed in every way to be a normal child.

Fatigue of Allergic Origin in Behavior Problems.—According to Randolph, the fatigue syndrome of allergic origin is a common cause of irritability and abnormalities of behavior in children. It usually results from chronic food allergy involving sensitivity to more than one food. Although any food ingested in often repeated feedings may be the cause of such chronic symptoms, sensitivity to wheat and corn is encountered most frequently. Clinically these cases fall into two groups: the first and larger group, as illustrated by 3 cases in boys 8 and 9 years of age, is characterized by the chronically tired, sluggish and depressed child. The second group, of which 1 case is reported in a boy 8 years old, is typified by the hyperkinetic, excitable child. The children in both groups are inclined to be irritable and fretful in their behavior and to be maladjusted in both the home and school. Their schoolwork suffers because of a characteristic difficulty in concentration and impairment of memory. Although this clinical picture may be the sole allergic manifestation exhibited by a child, it is more commonly associated with a history of one or more other expressions of clinical allergy. These children are most commonly considered nervous, a point of view that is not helpful in their treatment. When dealing with allergic children, the significance of psychic and emotional factors in the genesis of irritability and behavior problems may be judged to best advantage after the allergic reactions are brought under control.

Medical Treatment of Perforated Peptic Ulcer.—McClintock says that it is the practice in the Baltimore Marine Hospital to treat all patients with ruptured peptic ulcer by conservative measures. Only 1 death occurred in 35 cases so

treated. The case reported is of interest because there developed in the patient and was maintained for many weeks a large, asymptomatic, localized abscess of the peritoneum, apparently caused by spilled gastric juice. In spite of the fact that the general condition of this patient was poor, he recovered completely with conservative treatment.

Aerosol Therapy of Respiratory Disease.—Bryson and Grace say that experimental evidence indicates that to penetrate to the smaller bronchioles and alveoli of the lungs, aerosols must be composed of small particles of 5 microns in diameter or less. Large particles are undesirable, except for the treatment of infectious tracheitis, laryngitis and other diseases of the larger respiratory passages. The clinician must distinguish between the ordinary commercial atomizer, which produces relatively large droplets, and the nebulizer, which is constructed with some intermediate baffle to break larger particles into smaller droplets. If it is desired to confine therapy predominantly to the bronchioles and alveoles, the clinician should ascertain that the nebulizer produces with 5 per cent glycerin a fine smoke that floats in the air, rather than a spray capable of wetting objects placed a few inches from the orifice. Aerosol therapy is a form of topical treatment. Topical administration of antibiotics in detergent solutions may provide the physical advantages associated with reduced surface tension and the antibacterial advantages contingent on synergism and the reduced likelihood of drug-fast infection. Clinical experience of more than two years has shown antibiotic aerosol therapy to be a valuable supplement to parenteral treatment of respiratory disease, including intrinsic infectious asthma, bronchitis,

bronchiectasis, sinusitis and, more recently, tuberculosis. Except in selected cases, aerosol therapy should be attempted before there is resort to surgery. Case histories are given to demonstrate the therapeutic effect of aerosol therapy.

Emptying of Stomach at High Altitudes.—Nimch says that since he began to practice medicine in México, D. F., Mexico, more than twenty years ago, he noted during radiologic examinations that the emptying time of the stomach in normal persons is decidedly retarded in comparison with that estimated as normal and is different from that observed at lower altitudes. This observation and corroborating statements by others induced the author to study the causes of this phenomenon. He arrives at the conclusion that anoxia and the type of food are the most important factors that cause the retardation of the emptying of the normal stomach at high altitudes; the first by vagospastic and pylorospastic action and the second by chemical and mechanical action of the fats and condiments taken.

Hidradenomas of Vulva.—Cunningham and Hardy report 4 women with sweat gland tumors of the vulva and review the literature on this problem. To date about 80 cases have been recorded. Despite this paucity of reported cases, these are the tumors most commonly encountered in the vulva. Of 5 vulval tumors observed by the authors, 4 were of sweat gland origin. Small tumors are usually situated subjacent to the epidermis and appear as small cystic, elevated nodules. With an increase in size, the overlying epidermis may ulcerate, with eventration of the papillary contents of the cysts. These tumors are seen as fungoid or filiform reddish masses. Microscopically, the picture is usually that of an intracystic papillary tumor. Usually the tumors are discovered incidentally during routine physical examination and present no symptoms. Occasionally the patient notes a mass or complains of spotting of the undergarments by blood or secretion. As a rule these lesions are clinically benign. Only 3 of the 80 cases recorded have shown malignant characteristics. The authors consider these lesions analogous to the intraductal tumors of the breast. The basis for this belief rests on embryologic considerations, parallelism of clinical behavior and the morphologic similarity of the lesions. In the fetus a milk line develops which extends from the axilla to the groin. This is a manifestation of human phylogenetic evolution, and in our mammalian relatives breasts develop all along this line.

Coronary Diseases.—Although it is known that diseases of the heart are by far the most frequent causes of death, it is not generally appreciated that acute coronary artery diseases alone, with the possible exception of cancer, cause more fatalities than any other disease. There are two chief acute coronary artery diseases, (1) acute coronary insufficiency and (2) acute coronary occlusion. Master gives particular attention to acute coronary insufficiency, which greatly varies in severity. An episode may be associated with exertion, trauma, excitement and emotion, extremes of heat and cold, infection, excessive simultaneous use of tobacco, alcohol and food. It may be a consequence of operation, anesthesia, anoxemia of many types, carbon monoxide poisoning, acute hemorrhage, hypotension, hypothyroidism, hypoglycemia or adrenalin. It may result from status asthmaticus or from pulmonary infarction and embolization; it may occur reflexly from disturbances in the abdominal viscera. Prognosis of this condition is generally favorable, provided the precipitating factors are removed. The favorable prognosis of acute coronary insufficiency is in contrast to that of coronary occlusion, which occurs fortuitously; it may take place any time or anywhere and is not related to effort and excitement. It most frequently takes place during sleep and rest. The symptoms are crushing, substernal pain (not relieved by glyceryl trinitrate), nausea, vomiting, shock, fall in blood pressure, change in heart sounds, gallop rhythm, fever, leukocytosis and increased sedimentation rate. The illness is prolonged, and permanent changes in the heart usually ensue. At autopsy the coronary artery is completely closed by a thrombus, which is formed directly on an intimal plaque or originates from an intimal hemorrhage that has broken through the intimal lining. A hematoma within the intima may cause complete obstruction of the lumen without thrombosis. Treatment of acute coronary occlusion should be directed toward relieving the patient's symptoms. Drastic measures are contraindicated.

Intracavitary Radium Treatment of Carcinoma of Cervix.—Neary describes a new applicator for the treatment of carcinoma of the cervix uteri. Without exceeding the local doses normally arising in conventional techniques, a more than twofold improvement in the dose at the pelvic wall (5,000 r) is achieved. The predetermined radiation field cannot change during treatment, and it is maintained in correct relationship to the bony pelvis. The radium sources consist of 70 mg. in the uterus and two units of 140 mg. each in the vagina on the midline. The treatment time is seventy-two hours, leading to a total of 25,000 milligram-hours. Drastic modification of the distribution of radiation is brought about by massive platinum screens. The design of this applicator is not regarded as necessarily final or universally applicable. It has been found desirable to modify the uterine tube. The wider importance of the principle of screening for obtaining special dose distributions is stressed.

Nephritis in Textile Workers. R. Platt.—p. 771.

Malnutrition of Nervous System.—According to Brain it is often difficult to distinguish between intoxication and a deficiency. He discusses beriberi, Wernicke's encephalopathy, pellagra, war neuropathy and myasthenic syndrome. In the past there was a tendency to think that describing a disorder as toxic explained it, but it was only ignorance of the finer processes of the metabolism of the neurone that forced physicians to be content with such vague conceptions as intoxication and toxic polyneuritis. A normal constituent of food may be toxic only in the presence of vitamin deficiency or other deficiency—

e.g., maize in pellagra. Lathyrism gives rise to a spastic paraplegia. Denny-Brown believes that lathyrism has not been proved experimentally to be due to Lathyrus sativus and suggests that flour made from this pea may be deficient in tryptophan and that this may neutralize the action of a vitamin, the consumption of lathyrus thus bearing the same causal relation to lathyrism that the consumption of maize or cassava does to pellagra. Maize is toxic only in the sense that it leads to a tissue deficiency of nicotinic acid, and it might be considered that the crucial question is the state of the nervous system. Even in this instance the distinction between intoxication and deficiency is not clearcut. The author concludes that all that has been learned about malnutrition should prove that whatever happens to the nervous system will need increasingly to be considered from the standpoint not only of morbid anatomy but also of the chemistry of the nerve cell.

Nephritis in Textile Workers.—Platt points out that in an earlier issue of the *British Medical Journal* an article on oxygen poisoning contained the statement that "the inhalation of textile dusts is a steady source of death from nephritis and a group of conditions whose common factor is hyperpiesia." The data analyzed suggest that deaths from so-called nephritis in textile workers are in all probability due to hypertension and can be as easily explained by natural variations in the genetic constitution of an inbred population as they can by environmental influences. This should be borne in mind before making the assumption that such deaths are due to "the inhalation of textile dusts."

Metabolic Disturbances After Injury.—Beattie directs attention to an increase in the urinary nitrogen output following fractures in experimental animals and in well nourished human subjects. Poorly nourished persons do not show this response, at least not to the same extent as do well nourished persons. At least three factors condition the magnitude of increased nitrogen output in the "katabolic" phase—immobilization in bed, the severity of the injury and the nutritional state of the person at the time of injury. The urinary nitrogen output increases to reach a peak by the end of the first week after injury. The high nitrogen output may be diminished but not abolished by high protein diets. It has been shown that the urine during the period of high nitrogen output contains large quantities of corticosteroid material presumably derived from the adrenal cortex. After injury the body requirement for ascorbic acid (vitamin C) is apparently greater. Some of the increased demand may be due to an increased utilization in the adrenal cortex and the liver and some to the needs of the tissues at the site of injury. The increase in calcium output in the urine after injury is a potential danger, as insoluble calcium phosphate may be precipitated, leading to the formation of calculi.

Musicogenic Epilepsy.—Shaw and Hill assert that examples of epilepsy induced by musical sounds are clinical rarities, the most comprehensive review citing only 20 cases, some of which were not definitely established. The authors present the case of a woman, aged 44, in whom extensive clini-

cal investigations failed to reveal an acquired cerebral lesion, although the fit pattern, optokinetic response and interseizure electroencephalogram indicated an epileptogenic area in the left temporal lobe. The patient experienced increases of blood pressure, heart rate and respiration while listening to music. Fits could not be induced by pure tones, although the patient felt emotional to a tone of 512 cycles which persisted and was varied in loudness. Different kinds of music were invariably followed by a fit within five minutes. Electroencephalographic studies showed a constant pattern for the development of the fit. No change of rhythm was seen while music was played before the fit began. The cortical discharge began six or seven seconds after the clinical onset.

Prefrontal Leukotomy and Depersonalization.—Shorvon states that the distressing symptom of unreality both in self (depersonalization) and surroundings (derealization) can arise in the early stages of all neuroses and psychoses and in some organic conditions, but there are also patients in whom depersonalization is fundamental, the predominant and presenting symptom, existing almost alone as a clinical entity. Since a diminution in preoccupation with self and awareness of self is a frequent result of leukotomy, Shorvon thinks that this operation is indicated in intractable cases of the depersonalization syndrome where other methods of treatment have failed. He reports 5 cases of depersonalization syndrome for which prefrontal leukotomy was performed. Four patients lost their symptoms of depersonalization after leukotomy (2 immediately and 2 after several months), and the fifth patient has improved and is still improving.

Staphylococcus Pneumonia in Childhood.—According to Guthrie and Montgomery primary Staphylococcus pneumonia occurs in epidemic and sporadic forms. They observed at necropsy 55 cases of Staphylococcus pneumonia in children, all under the age of 7 years, two thirds of them being less than 6 months old, at the Royal Hospital for Sick Children, Glasgow. In addition one of them investigated in a maternity nursery an outbreak of Staphylococcus infection which included 16 cases of pneumonia. The 55 hospital cases consisted of 45 in which pulmonary consolidation was the outstanding feature and 10 in which the pneumonia was associated with suppurative bronchitis and bronchiolitis; in 2 it was accompanied by acute bronchiectasis and in 3 by pulmonary abscess. Staphylococcus aureus was isolated at necropsy in all the hospital cases, and in a few instances the organism had been obtained also during life from pleural pus and throat and nasal swabs. It was impossible to ascertain in the epidemic in the maternity nursery whether the Staphylococcus alone was responsible for this epidemic or whether it was associated with a mild type of virus influenza. The authors stress that Staphylococcus pneumonia is a grave disease with high mortality, particularly in infants. Pathologic changes vary according to the duration of the disease. The earliest stage is a hemorrhagic exudative reaction simulating the red hepatization of lobar pneumonia, and this is particularly likely to be found in infants. Premature babies have a poor resistance to the Staphylococcus, and in pulmonary infection death may take place with minimal pulmonary reaction, though the lungs contain abundant cocci. In view of the pronounced

sensitivity to penicillin of most strains of Staph. aureus, it appears that penicillin would offer the best chance of controlling the infection. The penicillin treatment can be combined with administration of sulfonamide drugs.

Transplantation of Teres Major and Latissimus Dorsi.—Zachary reports the case of a man, aged 30, who had been wounded by a shell splinter in the right side of the neck and below the angle of the right scapula. Nearly three years after the injury, the deltoid and biceps were working against gravity and weak resistance, but the external rotators of the humerus showed only a flicker of voluntary power. The patient's chief disability was the tendency of the arm to swing toward the chest when he lifted anything in the right hand. Transplantation of the teres major and latissimus dorsi to the outer side of the humerus was resorted to in order to restore external rotation of the arm. The author points out that this operation is a modification of that described by L'Episcopo and makes use of Henry's approach to the back of the humerus. He thinks that the operation described here may have important applications in the reconstructive surgery of the many brachial plexus lesions sustained in the war.

Acute Friedländer's Bacillus Pneumonia Treated with Streptomycin. C. E. Vickery and J. Gray.—p. 518.

Septic Sore Throat and Venous Thrombosis.—According to Reye sudden extensive thrombosis of veins as distinct from thrombophlebitis is not common. He presents 2 examples of venous thrombosis occurring in children, aged 6 years. In each case the illness began with a sore throat and cervical adenitis, severe orthochromic anemia early in the disease and pronounced neutrophilic leukocytosis. The first case concerned a girl who fourteen days before her admission to hospital had had a sore throat, frequent cough and enlargement of the cervical lymph nodes. Eleven days later she suddenly became pale and her abdomen became swollen. On the following day the pallor and abdominal swelling were more pronounced, and she began to vomit. She was admitted to the hospital at this stage. The red blood cells numbered 2,800,000 per cubic millimeter and the neutrophilic leukocytes 33,000. She was given a transfusion, but her condition did not improve, and she died. All organs were examined histologically, but only in the liver were any significant pathologic changes found. In this organ the entire system of hepatic veins was thrombosed. The rapidity with which death occurred was due solely to the peculiar site of election for thrombosis, since this resulted in rapid necrosis of the liver. In the second case, which concerned a boy, both feet and the distal half of the legs were gangrenous, the condition being more pronounced on the right side. Eight days after his admission spontaneous separation of the right foot occurred at the ankle joint. The right leg was amputated on the following day. Later, part of the left foot separated, but after that the gangrenous process in this leg receded. Were it not for the histologic studies on the amputated leg, it might have been assumed that the tissue necrosis was the result of arterial obstruction rather than of venous occlusion. However, the evidence for venous as against arterial obstruction was clear.

Basophil Stippling of Erythrocytes in Hyperthyroidism.—Nizet says that certain experimental and clinical observations indicate that the thyroid hormone has a stimulating effect on erythropoiesis. He decided to investigate whether patients with hyperthyroidism show increases in the erythrocytes with basophil stippling, a sign which suggests stimulation of erythropoiesis. A table listing 27 patients shows the results so far obtained. The ratio of stippled cells, observed on the dark field after staining with methylene blue, has been found higher in patients with thyrotoxicosis (4,000 to 40,000 per million) than in normal subjects (0 to 3,000 per million). The author investigated variations in the incidence of erythrocytes with basophil stippling in 11 patients with hyperthyroidism while they were undergoing treatment with various antithyroid substances such as thiourea and thiouracil. It was found that improvement in the hyperthyroid state following treatment was accompanied by a return to the normal level of erythrocytes with basophil stippling. In patients in whom treatment proves inadequate this decrease fails to take place or is extremely slow. The return to normal of basophil stippling is not accompanied by a parallel reduction in the reticulocyte count, which seems to indicate that the two elements differ. The author suggests that basophil stippling may be of value in the diagnosis of thyrotoxicosis.

Fever Therapy in Inflammatory Polyneuritis. H. Rosenhagen.—p. 233.

Cellulose in Dietetic Treatment of Ulcer Patients.—Pezold observed that three fourths of the patients with gastric and duodenal ulcer had disturbances in defecation, usually constipation, which frequently antedated the onset of the ulcer symptoms by a year or more. Abdominal palpation usually reveals disturbances in intestinal tonus and motility and roentgenoscopy corroborates these disturbances. Pezold has frequently observed that with the restoration of normal defecation and of normal tonus and motility the ulcer symptoms subside. Roughage (cellulose) is of great importance for the proper functioning of the terminal portions of the intestine. The author warns against a sudden change to a diet that is high in cellulose, particularly in patients who have long received a diet low in roughage. He recommends a gradual widening of the diet. After the patient has become accustomed to fruit and vegetable juices, finely grated raw carrots and apples can be added. Thick soup, gruels and potatoes with milk and eggs are the main constituents of the diet. The bread should be of the whole grain type. Of the vegetables, only the leafy types of the cabbage family and the legumes are omitted, because of their tendency to produce bloating; but other vegetables are given in liberal amounts.

Fever Therapy in Inflammatory Polyneuritis.—Rosenhagen points out that thirty years ago Guillain, Barré and Ströhl separated from the collective concept of polyneuritis those cases which were characterized by favorable course and typical changes in the cerebrospinal fluid; they regarded these

as radiculoneuritides. These patients had flaccid paralysis chiefly of the lower extremities, paresthesias, disturbances in sensitivity and weakening or loss of tendon reflexes. Examination of the cerebrospinal fluid revealed an increase in the protein level. Inflammatory polyneuritides of the Guillain-Barré type are frequently observed after diphtheria and other infectious diseases, as well as after chronic wound infections. The increased incidence of this disorder and the reduced tendency to spontaneous cure that prevails under present conditions made the need for effective treatment more urgent. Since this inflammatory polyneuritis is regarded as an allergic-hyperergic, serous, interstitial inflammation of the nerve root, the author resorted to artificial pyrexia by means of pyrifex (a colon bacillus vaccine). The results of this treatment are excellent with regard not only to the extent of the improvement obtained but also the time required. Improvement was often noticeable during the first week, that is, after from one to three injections of the vaccine. After two or three weeks even the serious cases were improved. The improvement in the neurologic disturbance was accompanied by improvement in the general condition of the patient and in the defense power of the organism (increase in weight and healing of chronic wounds.) Treatment with pyrifex is well tolerated and is less exhausting than is malaria therapy. Prognosis is the more favorable the earlier treatment is begun. The author recommends this treatment on the basis of observations in 16 cases.

Polio-myelitis After Vaccination and Injury.—Verjaal says that the nasopharynx and, more recently, the intestinal tract have been widely accepted as the probable port of entry of the virus of poliomyelitis. He reports 2 cases which indicate that there is also a possibility of a peripheral port of entry. In a child aged 1 year who was vaccinated on the left shoulder paralysis of the left arm with cerebrospinal fluid abnormalities characteristic for poliomyelitis developed on the fourteenth day after vaccination. The paralysis of the forearm recovered partly, the deltoid paralysis remained. A girl aged 15 contracted poliomyelitis with paralysis of the left leg in the course of a suppurating wound on the lower part of the left leg. After three years the paralysis has greatly diminished; however, the peroneus group lying just underneath the wound is still seriously paretic. Several similar cases have been described in the literature. The wound is usually considered to be the factor affecting the local or general resistance against the poliomyelitis virus. The described observations seem to indicate that the surface of the wound may serve as a port of entrance to the virus.

Pelger-Huët's Nuclear Anomaly of Leukocytes. False Shifting to Left.—Jonsson and his associates report 4 cases of this nuclear anomaly seen at Södersjukhus in not much over a year. It is characterized by a discrepancy between the nuclei in the immature form of the leukocytes and the mature structure. The nuclei are short and broad and seem somewhat smaller than normal. The cells with their dark coarse nuclei and abundant acidophilic plasma give the impression of being mature too early. The chromatin is so coherent that the nuclei either remain unsegmented or in only exceptional cases form more

than two segments. The designation "false shift to the left" is suggested for the anomaly. Only dumbbell-shaped and peanut-formed nuclei are pathognomic. Nucleoli were not observed. The sternal punctate shows a typical picture with increased number of myelocytes and metamyelocytes; the contrast between the immature form and the mature structure of the nucleus appears here also. In cases of "full carriers," or true Pelger anomaly, all the leukocytes are of Pelger type; in "partial carriers" there are both normal and Pelger leukocytes. Inheritance is dominant. Examination of seventy-seven relatives of the patients revealed 7 additional cases of the anomaly. Diagnosis of the anomaly is of practical importance.

*Treatment of Migraine with Histamine and Antihistamine Substances. L. Biró.—p. 794.

Histamine and Antihistamine Substances in Migraine.

—Biró felt that histamine desensitization should be effective in cases in which injection of histamine elicits an attack of migraine. Of 30 patients with migraine, 25 responded with an attack of migraine to the subcutaneous injection of 0.01 mg. of histamine, and this attack could be counteracted by the administration of ergotamine tartrate. Biró tried histamine desensitization in the aforementioned 30 patients by injecting histamine every second day in the following doses: 0.0001, 0.0001, 0.0003, 0.0005, 0.0008, 0.001, 0.009 and 0.01 mg. The last dose is never exceeded, but is administered at two day intervals ten times. The 5 patients who had not responded with migraine to the histamine were not benefited by the desensitization. The other 25 patients had severe forms of migraine, which had failed to respond to the customary treatments. Of these 8 remained free from symptoms for two years, and in 12 the desensitization treatment had to be repeated after six months. The repeated desensitization was more effective than the first treatment. Some of the patients, while remaining free from the one-sided headaches, experienced some of the equivalents of migraine, but these usually responded to treatment. The author reports experiences with the new antihistamine substance, "antistin," (2-[N-phenyl-N-benzyl-amino-methyl]-imidazolin). He found this substance as effective as ergotamine tartrate in arresting attacks of migraine in patients in whom such an attack could be elicited by injection of histamine. During periods that are free from attack this substance can be given orally, subcutaneously, intramuscularly and even intravenously. It causes no secondary effects even when continued for three weeks. Of 11 patients treated 9 remained free from attacks, and in the other 2 the attacks became less frequent.

*Epidemic of Cholera. A. P.—p. 791.

Peritonitis with Ascites and Eosinophilia.—Laederich and Mamou report the occurrence of severe, diffuse abdominal pains associated with fever, vomiting and diarrhea in a woman aged 35. This peritoneal syndrome continued for several days and was followed by mild ascites. A tentative diagnosis of tuberculous peritonitis was made, but the cytologic examination of the peritoneal fluid revealed the presence of a considerable number of eosinophilic cells. There was also eosinophilia of the blood and the bone marrow. The abdominal symptoms and the ascites subsided five days later. Inoculation into guinea pigs proved negative. In this case and a second the eosinophilic cells in the peritoneal fluid were partly polymorphonuclear, as were those in the blood, but in addition there was a large number of mononuclear elements of fibroplastic appearance which suggested a local and histocytic origin of the eosinophilia. This variety of tissue eosinophilia is relatively rare and presents a

new aspect of acute ascitic peritonitis which is amenable to treatment. It may be diagnosed erroneously as tuberculous peritonitis, but definite diagnosis can be made with the cytologic examination of the peritoneal fluid, the blood and the bone marrow.

Epidemic of Cholera.—Because of the present epidemic of cholera in Egypt, the French Ministry of Public Health has issued a memorandum to all French practitioners on the prophylaxis of cholera. The clinical picture of the disease and the differential and laboratory diagnosis are discussed and instructions for the isolation of the cholera vibrio are given. With regard to treatment emphasis is put on the considerable aid offered by the sulfonamide compounds. Sulfaguanidine and sulfathiazole, combined with intravenous injections of a 20 to 30 per cent concentrated solution of sodium chloride and with administration of adrenal cortex extract, are effective in combating the disease. Additional symptomatic treatment may be directed at combating dechloruration, the lesions of the intestinal mucosa and deterioration of the general condition.

*Gelatinous Cancer of Breast. H. Bogetti and P. Fiannaca.—p. 685.

*Bilateral Hypertrophy of Breast in Young Girls: Case. A. E. Nogues.—p. 691.

Gelatinous Cancer of Breast.—Gelatinous (colloid) cancer of breast is, as a rule, painless. The tumor grows slowly for a long time without complications. It is radioresistant and may rapidly change into typical carcinoma and produce metastases. The diagnosis is made on the following findings: (1) pitting of the skin of the breast, (2) the sensation of a viscous substance on palpation of the breast and protrusion of the nipple, which in the majority of cases does not eliminate any secretion. The prognosis is based on the result of histologic examination. Certain types of the tumor become highly malignant and metastasize to the ovaries. The therapy consists of radical mastectomy. A case in a woman 36 years of age is reported.

Hypertrophy of Breast in Child.—A girl 5 years of age had from birth a left breast which was larger than the right. Hypertrophy became pronounced at the age of 3 years and still more at the age of 5. Clinical and laboratory examinations showed that the breast growth was not of ovarian hormone origin. It was found during operation that the growth was a tumor of the estrogenic type. The author believes that in this case the tumor was made up of embryonic tissue which developed into an organoid tumor simulating mammary hypertrophy of very young girls.

*Method of Puncture Biopsy in Hospital Practice. G. Giraud and P. Cazal.—p. 2401.

Biliary Cirrhosis and Hanot's Disease: Precise Nosology Based on 12 Cases Studied by Puncture Biopsy. G. Giraud and P. Cazal.—p. 2407.

Pleural and Pulmonary Manifestations of Toxic Diphtheria. M. Janbon and J. Chaptal.—p. 2417.

Precise Nosology of Acute Leukoses. P. Cazal and L. Bertrand.—p. 2426.

Aspiration Biopsy.—Giraud and Cazal performed two hundred aspiration biopsies in the medical service of a hospital during the three year period 1944 to 1946. No untoward reaction or accident was observed. A cylinder of tissue is punched out from an organ. In this fragment of tissue the cells retain their histologic relationship, and the fragment may be sectioned in the same manner as any piece of tissue obtained by ordinary biopsy. The method lends itself to the examination of material aspirated from compact organs whose parenchyma is not diffuent, particularly the liver, but also from enlarged kidney, thyroid gland, superficial or deep tumors and bones. Diagnosis in the case of an enlarged liver is particularly aided by aspiration biopsy, which makes it possible to study lesions of the various types of hepatitis, hypertrophic cirrhosis, biliary cirrhosis, pigmentary cirrhosis, cancer of liver and hepatomegaly resulting from pathologic changes in the blood. Aspiration biopsy is also valuable as an aid to prognosis by revealing the extent and gravity of the lesions.

Book Notices

Diagnosis and Treatment of Menstrual Disorders And Sterility. By Charles Macer, M.D., F.A.C.S., Assistant Professor of Gynecology and Obstetrics, Graduate School of Medicine, University of Pennsylvania, Philadelphia, and S. Leon Israel, M.D., F.A.C.S., Instructor in Gynecology and Obstetrics, School of Medicine, University of Pennsylvania. Second edition. Cloth. Price, \$7.50. Pp. 576, with 173 illustrations. Paul B. Hoeber, Inc., 49 East 57th St., New York 16, 1946.

This book was written to help the general practitioner with the diagnosis and treatment of menstrual disorders and sterility. This goal was accomplished so well in the first edition that a revision is timely. In this second edition the contents have been brought up to date. Several new chapters have been added.

The first several chapters of the book are devoted to the anatomy and physiology of the glands of internal secretion which control the reproductive organs and the structures themselves. The various abnormalities of the menstrual function are discussed under such headings as dysmenorrhea, amenorrhea and uterine bleeding. One chapter is devoted to the endocrine aspects of pathology of the breast. Sterility of the male and female are discussed in several chapters.

In general the information presented is sound; however, there is a tendency to exploit the authors' own experiences. This is particularly true in discussions of therapy, where there are many differences of opinion. In spite of these minor criticisms the book is clear and readable and is devoid of much controversial scientific data which would only serve to confuse the general practitioner. The book can be recommended to any one interested in this special field.

The publisher is to be congratulated on the general appearance and format of the book.

Vegetative Funktionen und Zwischenhirn. Von Dr. W. R. Hess, o.B. Prof. der Physiologie an der Universität Zürich, Zürich. Erscheint gleichzeitig als Supplementum IV der *Helv. physiol. acta*. Cloth. Price, 12 Swiss francs. Pp. 65, with illustrations. Benno Schwabe & Co., Klosterberg 27, Basel, [n. d.].

This small book, which appears also as a supplement to the *Helvetica Physiol. Acta*, summarizes Hess's work on diencephalic functions and is based largely on physiological stimulation experiments in the unanesthetized cat. It thereby supplements the work of American authors who under the leadership of Ranson studied this problem in anesthetized animals. Of great interest is Hess's finding that the diencephalon can be subdivided into an anterior area which elicits largely parasympathetic reactions such as fall in blood pressure, constriction of pupil, salivary secretion, emptying of the bladder and rectum, and decrease in respiration and in a posterior sympathetic area causing rise in blood pressure, rate of heart and respiration and pupillary dilatation. These autonomic reactions are associated with changes in excitability of the somatic nervous system, which are diminished by the parasympathetic and increased by the sympathetic area. This somato-autonomic integration seems to be the chief function of the diencephalon. The book is beautifully printed and illustrated. The complete omission of the pertinent literature is to be regretted.

Diseases of Children's Eyes. By James Hamilton Doggart, M.A., M.D., F.R.C.S., Ophthalmic Surgeon, Hospital for Sick Children, Great Ormond St., London. Cloth. Price, \$10. Pp. 288, with 210 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

The need for a textbook on children's eyes, in English, has been felt for some time. This volume, however, is primarily for the ophthalmologist who treats children, and the great need is for a textbook which the pediatrician would have available to enlighten him, and perhaps the general practitioner, in the specialty of the eye, just as other textbooks have been issued concerning the child's heart, lungs, and other organs.

The author has had much and excellent experience as an expert ophthalmologist in a children's hospital, and the book well illustrates the various difficulties which he has encountered and the methods of overcoming these dysfunctions and diseases. In addition to his own experiences he has drawn heavily on all of the important textbooks published in England concerning all

phases of the eye. Excellent illustrations both in black and white and color have been culled from the works of Wolff, Ida Mann, Sanford Gifford and the superb plates of Hamblin. The chapters, as to the approach to the eyes of infants and children, are well worth the perusal of the ophthalmologist, pediatrician and general physician. The American physician may have some difficulty with the English terminology and references to drugs. The index is complete, and the format leaves little to be desired. The drawings and color pictures by Miss Trotman are numerous and reveal to the full her special talent for eye illustrations.

Buchanan's Manual of Anatomy. Edited by F. Wood Jones, D.Sc., M.Sc., M.B., Sir William Collins Professor of Human and Comparative Anatomy at the Royal College of Surgeons of England, London, assisted by E. L. Patterson, M.D., B.Sc., S. Mothershead, M.D., B.Sc., F.R.C.S., T. E. Barlow, M.D., M.R.C.S., L.R.C.P., F. R. Wilde, M.B., Ch.B., B.Sc., and Jessie Dobson, M.Sc., B.A. Seventh edition. Cloth. Price, \$10. Pp. 1616, with 896 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This manual appears to be entirely out of line with the strong current tendencies of publishers as well as teachers to present anatomic material in a highly colorful and artistic fashion. There are numerous drawings which do not serve the purpose for which they have apparently been intended. Some drawings are crude, others are unusually crowded with detail, while still others show evidence of need for factual editing. The presence of a considerable number of radiographs enhances the text, but even here the absence of labels prevents the student from adequately interpreting the plate with any degree of authenticity. The reference to clinical application of anatomic facts is a distinctly desirable and important feature.

The chapters dealing with terminology and development are on the whole desirable and instructive. The chapter on osteology is entirely too extensive for a "manual." The chapters devoted to the description of the upper limb, lower limb, abdomen and thorax are in conformity with the general purpose of the text. The chapters on the nervous system, eye and ear, have more histologic detail than is warranted. The glossary is a valuable addition to the text.

In general, it may be said that the regional system of presentation, which is employed here, is probably more practical for a student in the dissecting laboratory than is the systemic mode of presentation. It is doubtful, however, whether a present day manual should be written on the assumption that the more anatomic detail a student of medicine or a practitioner is exposed to the better a physician he will be. This book may become very useful in the anatomic laboratory in connection with dissection when it is more carefully edited and when the illustrations are brought up to modern standards.

Memoranda on Medical Diseases in Tropical and Sub-Tropical Areas. Great Britain, War Office. Eighth edition. Cloth. Price, 7s. 6d. Pp. 396, with 113 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1946.

This edition has ninety-five pages and seven new plates more than the previous edition (reviewed in *THE JOURNAL* Feb. 27, 1943, p. 712). The volume is intended "as a companion, not as a rival to standard works."

Three sections have been dropped and five new ones added, namely, infective hepatitis, leprosy, nutritional diseases, sulfonamide drugs and tropical eosinophilia. Basic information remains unchanged but there has been extensive revision and many sections have been completely rewritten. This has resulted in the expurgation of much material of the previous edition which was generally considered unacceptable in this country.

The section on arthropod pests, except for some of the flies, has been completely rewritten and an appendix of ten pages is devoted to the various uses of DDT. "Atabrine" has been given due credit for reducing the incidence of blackwater fever and previous large doses of alkali are no longer indicated. The heading "heat stroke" has, at last, been dropped and replaced by "heat effects" which includes prickly heat and sunburn. Hepatic abscess, as such, is gone, but is included where it rightly belongs, as hepatic amebiasis.

In malaria, the exo-erythrocytic phase is barely mentioned. Under "factors governing diagnosis," "the result of examina-

tion of well stained thick or thin blood films" is now in first rather than fourth place. Four pages on suppression and prophylaxis have been added and Ascoli's treatment has, at last, been dropped.

The Russian work on the dry or urban and the moist or rural form of cutaneous leishmaniasis is included. One finds no mention of the newer raticides in plague. Rickettsial diseases have been expanded from fourteen to twenty pages and spruce has been rewritten.

Throughout the book emphasis is placed on prevention and control, and much of the new material reflects the experience of the British in the North African campaign.

Die Chirurgie im Einklang mit dem Leben. Von René Leriche, Professor am Collège de France, Paris. Mit Vorwort und Einführung von Dr. Joachim Beer. [Ins Deutsche übertragen von K. Vöchting.] Cloth. Price, 9 Swiss francs. Pp. 212. Basel: Benno Schwabe & Co., 1946.

René Leriche is one of the most prominent living French surgeons, his life work is devoted to the ideal of coordinating the art and science of surgery with the general physiologic and biologic conceptions originated by such masters as Pasteur and Lister. As early as 1914, Leriche was full of praise for the surgical methods taught by Halsted in Baltimore, methods based on the conviction that surgery can be nothing else but applied biology. Leriche stated more than twenty years ago that the "heroic" times, when the surgeon considered amputations and resections of main organs his pride and accomplishment, were over. He recognized that the experimental work of Claude Bernard applied by the surgeon would lead to entirely different procedures. Instead of crudely removing a diseased organ, the surgeon should endeavor to correct the pathologic process of a tissue by regulating the biologic conditions. Through resection of a sympathetic ganglion or similar operations on the vegetative nervous system, the abnormal blood supply, the disturbed hormonal balance would be reestablished.

Such thoughts sound like prophecies to those who live in an era where resection of the vagus nerve seems to displace the great radical gastric resection in surgical treatment of ulcer patients.

Several years ago Dr. Joachim Beer, a pupil of Leriche when he occupied the chair of the Surgical Department of the University of Strassburg, undertook to publish a number of lectures and essays of his teacher. The book, which appeared in French, was a great success. The compositions are written in a style which avoids technical terms as much as possible, and they are therefore accessible to most of the educated public. The book includes sketches and reminiscences of great scientists with whom Leriche had contact, such as his teacher Antonin Poucet, Halsted, Cushing and others. The German translation, recently published, will find many readers to whom the original was unavailable. An English translation would undoubtedly be warmly received.

Researches on Normal and Defective Colour Vision. By W. D. Wright, A.R.C.S., D.Sc. With a foreword by L. C. Martin, D.Sc., A.R.C.S., D.I.C., Professor of Technical Optics, Imperial College of Science and Technology, London. Cloth. Price, \$10. Pp. 383, with 233 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

Professor Martin's foreword gives an adequate value of the worth of this work by Wright and his co-workers and is therefore quoted in full: "I greatly appreciate the invitation to contribute a foreword to Dr. Wright's book, though his researches have made his name so well known in the world of Colour that any recommendation from myself is superfluous.

"The book will, of course, remind readers of its predecessor, *Researches in Colour Vision*, by Sir William Abney, a book which brought together descriptions of many lines of inquiry, the results of which have had a most profound influence on subsequent work. Nevertheless, it was realised that the experimental equipment of Abney's time left much to be desired when judged by modern standards, and I was gratified when, in 1926, the Medical Research Council responded with enthusiasm to my suggestion that a new and thorough experimental investigation of the characteristics of both normal and abnormal colour vision should be taken in hand. As Dr. Wright truly remarks in his preface, we owe much to Sir John Parsons and Professor Hartridge in the inception of the work, for experience had

shown that the advice of experienced physiologists in such a borderline subject is indispensable to the physicist, though physics and optics have contributed their characteristic rigour to the experimental methods adopted with such success by Dr. Wright. While the fundamental problems of colour vision are still unsolved, the by-products of these researches are of great technical and scientific importance especially in relation to colour specification and measurement.

"Much still remains to be done in all aspects of this subject, and the pace set by developments in instruments abroad, makes it essential that the financial support (generously accorded hitherto) should be given a fair chance in competition with other laboratories." In the preface, Wright says: "this book should be regarded first and foremost as a record of experimental data, with theoretical discussion and speculation occupying a very secondary position. Although I have no serious doubts about the fundamental correctness of a three-response theory along the lines proposed by Young and Helmholtz, I would prefer at the present time to be somewhat lukewarm and tentative about my espousal of one theory or another. Several novel ideas have been advanced during the past few years and in so far as they act as a 'ferment' from which the enthusiasm to embark on fresh investigations is engendered, they are to be welcomed, yet for myself I believe that more experiments rather than more theories are the primary need. So little is known about so much that the distinction between theory and guesswork is decidedly blurred; in that case discussion about the merits of any particular theory is merely time- and energy-consuming with little to show for it at the end. There is not even the excuse that a research program is difficult to lay out without a theory to serve as a guide, for the number of experiments awaiting experimenters is very great. It may be hoped that this book will serve both as a useful pointer to some of the more profitable lines to be followed and as a stimulus to get on with the job." After a basic discussion of the visual organ and visual processes, the author delves further into visual perception. His own investigation deals with the construction of the colorimetric equipment and a record of the results of experiments with such an equipment. Finally, a classification of defective color vision is restated from the results of his experiments. An index of authors and one of subjects completes the volume. The format is excellent. For those interested in the past and future work on color vision, this volume is the last word.

Pediatric Gynecology. By Goodrich C. Schauffler, A.B., M.D., Assistant Clinical Professor of Obstetrics and Gynecology, University of Oregon Medical School, Portland, Oregon. Second edition. Cloth. Price, \$6. Pp. 380, with 75 illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

Pediatric gynecology is a special field in which neither the pediatrician nor the gynecologist had a special interest prior to the publication of the first edition of this book. The problems of the reproductive organs peculiar to childhood and adolescence were emphasized and brought together in one small volume which met wide approval. The present edition brings the material up to date since the publication of the first edition in 1941.

The book discusses normal anatomic and physiologic changes as the child develops through puberty, adolescence and maturity. There are few pathologic conditions at this period, but they are discussed fully. The functional abnormalities of the reproductive organs are treated intelligently. Perhaps more space could be devoted to the menstrual irregularities associated with adolescence and maturity. The environmental viscera such as the peritoneum, the bladder and the rectum are likewise considered. There are pertinent chapters on the social service and medicolegal aspects of this special field.

The psychologic approach to the small patient, whose confidence may be difficult to obtain, is a real contribution. The author spends considerable time in describing the minutiae of a pelvic examination that will not utterly destroy the child's faith in the physician. The appendix contains a useful table listing the hormonal substances and one containing a list of the agencies interested in child welfare. The book can be recommended to the physician and the specialist who treat the little girl as she grows to maturity.

Lehrbuch der gynäkologischen Diagnostik für Ärzte und Studierende. Von Dr. W. Neuweller, a. o. Professor für Geburtshilfe und Gynäkologie an der Universität Bern. Bern. Sammlung Medizinischer Lehr- und Handbücher für Ärzte und Studierende, III. Band. Cloth. Price, 58 Swiss francs. Pp. 474, with 106 illustrations. Hans Huber, Martinstrasse 9, Bern 16, 1946.

This volume on gynecologic diagnosis, which comes from one of the few European clinics undisturbed by the recent war, is a welcome contribution. Major emphasis is placed on diagnosis in this special field, touching on therapy only to the extent necessary for completeness. The book consists of two parts. The general section discusses history taking, physical examination, instrumental examinations which include all the available methods of establishing a diagnosis and special examinations. Under the latter heading are included visualization and the examination of all the orifices of the reproductive organs and their environmental structures, by such methods as urethroscopy, colposcopy and rectoscopy. The second section is devoted to the various pathologic conditions affecting the pelvic organs, the cellular tissues and peritoneum of the pelvis and the abdominal wall. Each organ and structure is treated as an entity. The diagnosis of each complication is discussed in detail and every symptom and finding is evaluated carefully. The differential diagnosis is included. The text is made more lucid by numerous diagrammatic illustrations of the palpatory findings on vaginal examination as well as numerous gross and microscopic photographs of the involved pathology. There are over four hundred illustrations, sixteen of which are in color. There is a page of key references and a complete index. The publishers have done a good job of printing except for poor reproduction of many of the illustrations. The book can be recommended to students and physicians who can read the German language.

Altérations de la rétine en rapport avec les affections générales. Par Paul Bonnet, professeur de clinique ophtalmologique à la Faculté de Lyon. Lyon. Atlas ophtalmologique, II. Rapport présenté à la Société française d'ophtalmologie le 18 mai 1947. Paper. Price, 1,500 francs. Pp. 252, with 83 illustrations. Masson & Co., 120 Boulevard Saint-Germain Paris 6^e, 1947.

By means of detailed and well documented case reports, the author presents a number of retinal conditions that are probably frequently present but often unobserved in the course of certain general diseases. He has confined his attention mainly to diseases of the blood, diabetes, infectious states and a few other conditions of lesser significance. His comments are worthy of note and should interest the general medical reader as well as the ophthalmologist. The volume is a good companion to its predecessor.

Endoskopie der Harnröhre: Diagnostik und Therapie. Von Dr. Alois Gillingar. Band II, Wiener Beiträge zur Urologie, herausgegeben von Prof. Dr. Richard Uebelhoer. Boards. Price, \$1. Pp. 68, with 38 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1947.

This monograph on urethral endoscopy consists of four chapters. The first chapter is brief and is devoted to a description of endoscopes. The second chapter describes endoscopic examination and treatment of the anterior urethra and constitutes the main body of the work. This is followed by shorter chapters concerning the posterior urethra and female urethra.

The text is clearly and simply written; the colored illustrations are sufficient in number and adequate in detail. The amount and types of local treatment which the author prescribes for lesions of the anterior urethra appear excessive. The book can be recommended for a simple treatise on urethral endoscopy.

Varicose Veins of the Lower Extremity. By Anthony M. Barone, M.D. With a foreword by Geza de Takats, M.D., M.Surg., F.A.C.S., Associate Professor of Surgery, University of Illinois, College of Medicine, Chicago. Paper. Pp. 51, with 10 illustrations. Chicago: The Author, 1945.

This small monograph is an excellent primer and is unique in the way in which the subject is presented. It is profusely illustrated, showing the normal anatomy of the superficial venous system of the lower extremity and the various types of varicosities. Not only varicosities but also complications, such as thrombophlebitis and phlebothrombosis and pulmonary embolism, are considered. The various diagnostic tests are adequately described, both pictorially and by description. The treatment is discussed concisely. This is an excellent book for the practitioner of medicine.

Das Auge als Subjekt: Das Wahrnehmungsbild und seine Prüfung. Von Dozent Dr. Fritz Rössler, Vorstand der Augenabteilung der Krankenkassaklinik "Rudolfstiftung" in Wien. Cloth. Price, \$13.20. Pp. 191, with 122 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1947.

The subject of the physical and physiologic characteristics of the eye have been elucidated since the time of Euler in 1753. The most prodigious work was that of Helmholtz, who laid the ground work for the present author's thesis on the use of the cobalt lamp for the objective study of the refraction of the eye. Helmholtz's work appeared in 1866 with rather crude instruments. Since then, Snellen, Donders and finally Gullstrand have perfected this method.

The author reviews the work of previous authorities and then illustrates by beautiful color plates the results of many years of work with the new cobalt lamp.

Certainly, he has brought to modern perfection this method of retinoscopy. The detailed mathematical formula and concise theoretic conclusions leave little to be desired.

The literature is covered in full with a long bibliography. The index is short but adequate. Too much emphasis cannot be given to the generous number of black and white and colored illustrations. It is questionable that the method described by Rössler will ever "catch on" in other than the Germanic countries, but for those interested in a relatively new twist to the theoretic vagaries of the physical and physiologic phenomenon to be found in the human eye, this small volume is more than adequate.

Building Up a Successful Medical Practice. By Rodolfo V. Guiang, M.D. Paper. Pp. 91. High Grade Press, New York, 1946.

Dr. Guiang's guiding star in writing this book was Dale Carnegie. He says that "every practitioner who does not know how to deal with his patients and his colleagues should master (Mr. Carnegie's) book ('How to Win Friends and Influence People')." He became a convert in the following manner. "Before I knew this way, I had tried several means by which I could be known by the people. I hanged a big signboard in front of my office. I spent some money advertising my name in newspapers, magazines, programs and souvenirs. I attended social gatherings to be seen by people. All of these methods brought me no significant result as that when I looked directly at people, and greeted them with smiles."

As to how to attract patients, he says that when no patients come to him, he visits his relatives or friends. He then says, "If my presence in their house does not invite anybody to consult his complaints, I will try to observe any person in the household who looks sick. If I see a child is pale, I will ask the mother since when did she notice pallor in the child. One question leads to another until the mother will request me to examine him. After the examination, I will advise the mother to bring the child to my office with specimen of his stool. The presence of these friends and relatives in my office increases the number of patients seeking my advice."

There is much more of the same, and some of it is hilarious reading.

Penicillin Therapy Including Streptomycin, Tyrothricin and Other Antibiotic Therapy. By John A. Kolmer, M.S., M.D., Dr.P.H., Professor of Medicine in the School of Medicine and the School of Dentistry, Temple University, Philadelphia. Second edition. Cloth. Price, \$6. Pp. 339, with 27 illustrations. D. Appleton-Century Co., 35 W. 32d St., New York 1, 1947.

This second edition of Dr. Kolmer's book dealing with antibiotics is completely rewritten and enlarged, and much new material has been added. Each chapter contains an adequate and extensive list of references. In this book one can find the results of the treatment of various disorders as they are reported in the literature. It is an excellent reference book and one that can be read with profit by all physicians.

The Health Story in Hawaii. Paper. Pp. 109, with illustrations. Public Health Committee, Chamber of Commerce, Honolulu, 1947.

"The Health Story in Hawaii" is a picture book showing all phases of health on the islands. With no effort to propagandize the booklet presents its story clearly and precisely. The pictures, the charts and the description are well chosen and make for easy reading. A wealth of information is contained in the booklet.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

LITTLE STROKES

To the Editor:—A male patient, aged 71, is asymptomatic except for a moderate hypertension, 168 systolic and 88 diastolic. An extra systole has been found by one physician. While descending from an upper berth about two months ago the patient dropped about 2 feet; he was jarred and had headache for about half a day. Two weeks later he had a sore, stiff, left calf muscle. About one week ago (September 23) he awoke with a headache—most unusual with him—which disappeared after more sleep and breakfast. After breakfast, standing at the sink on a rug, he noticed a heavy sensation in his left foot. Later in the day the leg became "weak," and next day his arm felt "a little weak." His appetite is fine. He had no other symptoms. The episode was called a "slight stroke." He was not confined to bed, as the consultant considered it unnecessary. He has steadily improved, leg symptoms have always been worse than in the arm. Does our diagnosis seem correct? Could symptoms indicate embolism? What treatment is suggested now? Please outline diet and give effect on the patient of coffee, beer and alcoholic drinks now or in the future. Paralysis did not occur, and all reflexes of the patient were normal.

M.D., Nebraska.

ANSWER.—The diagnosis of little stroke appears to be correct. They are due usually to thromboses of small blood vessels. There is no logical treatment. One can give a tablet of "lipoiodine" (ethyl ester of diiodobromic acid) every day, interrupting treatment every two weeks. It is unwise to limit diet or activities or to moderate drinking or smoking. There is no evidence that it helps, and it annoys and depresses the patient. He should be told what is true, namely, that some persons go many years before they have another attack. Most patients do not get hemiplegia but just grow old, forgetful, thin and weak. This is probably one of the commonest ways of ageing. The process has been described in detail by Walter C. Alvarez in *Geriatrics* 1:189-216 (May-June) 1946. He described the care of these patients in the *American Journal of Nursing* 47:169-170 (March) 1947.

POSSIBLE PERIODIC INTESTINAL BLOCKAGE

To the Editor:—A white man aged 54 has chronic congestive heart failure of at least three years' duration from a long-standing hypertensive cardiac disease. The failure is reasonably well controlled by "purodigin" (digitoxin), ammonium chloride, mercurial diuretic and restriction of activity. He receives one injection of a mercurial preparation weekly and averages a loss of about 7 pounds (3 Kg.) per week. He has a poorly functioning gallbladder and a chronically enlarged liver but shows no evidence of impaired hepatic function. For several months he has had attacks of extreme weakness, pallor, profuse sweating, nausea, vomiting, severe abdominal cramps and an urge to defecate. These attacks last up to thirty minutes during which he loses a tremendous amount of fluid from perspiration and has a cold clammy skin, without change in pulse rate or rhythm or fall in blood pressure. The attacks may occur at any time of the day or night without relation to meals. On several occasions he has lost consciousness and convulsive movements have occurred. The cramps have been controlled by antispasmodics but the pallor, sweating and all other symptoms continue to occur. Hypoglycemia has been considered. A blood sugar determination at the end of one episode revealed a level of 110 mg. per hundred cubic centimeters. High carbohydrate feeding at the time of the attack has not been adequately tried because of aversion to food and concurrent vomiting. Normally his appetite is good and he eats well. Intermittent partial obstruction of the small bowel has also been considered. What further studies are suggested for diagnosis?

G. R. McClary, M.D., North Miami, Fla.

ANSWER.—The attacks of severe abdominal cramps with urge to defecate accompanied by nausea, vomiting, profuse sweating, extreme weakness and pallor and even loss of consciousness do not fit the picture of congestive heart failure. One must assume that they have a definite but independent causation, for edema of the intestine is not likely to precipitate such attacks. The best explanation for these episodes is that of periodic intestinal blockage, which should be further considered. What is the abdomen like during the attacks? Is there increased peristalsis? Is there an abdominal mass? What is the intracranial state? It seems likely that the weakness and faintness are secondary rather than part of the central nervous mechanism behind the attacks. It also is unlikely that intra-abdominal embolism or stone in kidney or gallbladder can be blamed. Further study of the gastrointestinal tract itself would seem to be advisable.

RASHES AFTER VACCINATION

To the Editor:—Recently I vaccinated a boy 16 months of age on the left shoulder and obtained positive vaccinia reaction. With the development of the pustule there appeared a reddish streak, ½ inch (1.3 cm.) wide, from the pustule down the outer aspect of the arm and forearm to the base of the thumb, slightly interrupted at the elbow. The cutaneous area of the streak was not pruritic, inflamed or associated with other lesions. After a week, when the scab was forming over the vaccinal lesion, the streak whitened and flakes of epidermis could be rubbed off. The streak lasted about four months without discomfort although treatment was not prescribed. At disappearance there remained a mild maculopapular eruption of eczematoid type on the neck and shoulder areas. What was this lesion? Lymphangitis, eczema or allergic dermatitis appear unlikely. There were no herpetic lesions. Although the character of the lesion was consistent with tinea, I do not believe it was that.

L. V. dos Remedios, M.D., San Luis Obispo, Calif.

ANSWER.—When a vaccination is performed high up on the arm or shoulder, there seems to be less likelihood of the axillary glands swelling than when the inoculation is done near the insertion of the deltoid muscle. When the local reaction is particularly severe, an extensive erythema, cellulitis, erysipelas or lymphangitis may develop. In these conditions the lymphatics of the skin are affected. Had the vaccination been performed some distance below the shoulder with involvement of axillary glands and lymphatic channels the lymphangitis would have occurred on the inner surface of the arm. The case cited is most unusual. It seems likely that the red streak was due to a lymphangitis. The fact that there was peeling of the epidermis is evidence that there had been some inflammation of the skin.

Several different types of generalized rashes may occur after successful vaccination. The commonest of these resembles German measles. When rashes of this kind are seen they frequently appear from seven to ten days after vaccination. If the maculopapular eruption on the neck and shoulders did not occur until four months later, probably it was not related to the vaccination.

FLUORIDE POISONING

To the Editor:—What is the information regarding the length of time of urinary excretion of fluorides in a patient suffering with fluoride poisoning?

M. R. Warden, M.D., Danville, Ill.

ANSWER.—Permanently, because all persons regularly excrete fluorides up to 1 mg. daily. This normal output represents the fluorides commonly present in foods and water. After occupational exposure to fluorides or after their deliberate addition to food or water, an excess urinary output may persist for five weeks or longer after the last intake. The amount of fluorides introduced probably influences the duration of continued excess excretion. Excretion as high as 43 mg. per liter of urine has been reported during the time of occupational intake. Largent (Largent, E. J.: Urinary Fluoride Excretion Among Men Employed in Alkylation Plants Using the Hydrogen Fluoride Process, *J. Indust. Hyg. & Toxicol.* 29:53 [Jan.] 1947) states the present concepts of fluoride entry into human beings in relation to storage and excretion, including the possibility of some elimination in perspiration. That publication includes references to the literature which embrace all recent investigations. One paragraph from the report of Largent is included as pertinent to the query: "In the course of several intermittent periods of observation totaling one hundred and eighty-three days during which fluorides were added to the diet of the subject to the extent of 6 mg. daily, it was estimated that 0.64 Gm. of fluorine had been stored in the subject's tissues. During the control observations that followed, the urinary level of fluoride excretion remained elevated for five weeks; even in the eleventh week of this period of control observations the urinary excretion was 50 per cent greater than the total intake of fluorine in the diet. This strongly suggests that retention of fluorine in the tissues had occurred at this level of fluoride intake."

UNDULANT FEVER IN CHILDREN

To the Editor:—I have never seen a patient with undulant fever under 7 years of age. Is there any cause for this? If this disease is due only to milk why don't babies have it?

E. C. Gaines, M.D., Buffalo Lake, Minn.

ANSWER.—Undulant fever does occur in children under 7 years of age. On the island of Malta, where the disease is prevalent, approximately 43 per cent of the cases reported each year are in children under 5 years of age. Several of the cases occur in babies under 2 years of age. The disease has also been reported in young babies in Mexico.

ELECTROSTATIC BULB LUMINESCENCE

To the Editor:—As a student I attended clinics at Montefiore Hospital, New York, which had a wealth of neurologic patients. Among these was a young French engineer (a graduate in physics at a French university) who was about 30 years of age. This man was, as I remember, a victim of "multiple sclerosis" and was brought in a wheelchair because his legs were chiefly affected. After the case had been presented our instructor remarked that the patient had exhibited a strange and inexplicable faculty. This the patient proceeded to exhibit in a darkened room. Taking an ordinary 40 watt light bulb in his one hand by grasping it at the base, he would rub his cupped hand over the glass portion, whereupon the bulb glowed faintly with a kind of bluish, phosphorescent light. By rubbing more vigorously in a circular direction enough illumination was produced that time could be told by a nonluminous pocket watch and the features of the patient and students present could be faintly but definitely distinguished.

The patient had his sleeves rolled up and his hands were empty save for the light bulb. I do not believe that there was any legerdemain employed, as I am familiar with "magic" and with methods of deception in manipulation, having been vice president of a "Magic Club."

The patient was highly intelligent and well educated scientifically. He repeatedly stated that he was unable to explain the phenomenon and emphatically denied any possible claim to its being a so-called "psychic phenomenon."

The incident arose again in my memory during a recent discussion with other physicians. Is there a satisfactory explanation which is based on known physical facts?

It is needless to add that when we students tried to duplicate the production of light by rubbing the bulb ourselves we were unsuccessful.

M.D., New York.

ANSWER:—The patient at the Montefiore Hospital produced the luminescence in the lamp bulb by the production of static electrification induced on the inside of the bulb, by frictional static rubbed on to the outside by his hand. At the moderately low gas pressures then common in lamps the gas-ionic conductivity was high and the induced charge was carried by the gaseous ions across to the filament and to ground (the patient in this case).

In addition the phenomenon may have been amplified because he was on a presumably rubber-tired wheelchair on which a large static charge might have been acquired. Sufficient data are not submitted to complete the picture of the capacitance effects that thus might have intensified the phenomenon. The writer unscrewed a 60 watt bulb, took it into a dark closet and, when the eyes were somewhat dark-accommodated, held the socket end in one hand and stroked the bulb with the other. A clearly observable luminescent flash resulted—not repeatable, however. On stroking the bulb with a silk handkerchief flashes of longer duration and greater brilliance were produced. This too was not repeatable after a few strokings until the handkerchief was rubbed against wool. Then it was.

Conditions of excessively low humidity greatly assist such effects in cold dry winter weather. The reporting of an unexpected phenomenon of this sort of course is not quantitatively reliable.

The essence of the explanation is electrostatically produced luminescence within the low pressure bulb by external friction under conditions of relatively low humidity.

TREATMENT OF HERPES ZOSTER

To the Editor:—A man aged 65 had herpes zoster involving the left side of the face and scalp thirteen months ago. He still has hyperesthesia and cannot bathe or shave his face. Please give treatment suggestions.

M.D., Texas.

ANSWER:—Postherpetic neuralgia may be difficult to relieve in those cases lasting more than three months. Many drugs have been tried for the relief of such pain. The following treatment is suggested in the order given: (1) application of 1 per cent procaine hydrochloride ointment; (2) application of heat over the involved area; (3) roentgen ray exposures to the geniculate and gasserian ganglions; (4) section of the posterior root of the left trigeminal nerve; and (5) use of morphine and dihydromorphinone hydrochloride in cases in which the foregoing measures have failed.

TREATMENT OF CANCER

To the Editor:—I should like information, references, or advice on the use of trypanosome vaccine in the treatment of cancer.

Robert G. Ward, M.D., Brooklyn.

ANSWER:—There is no conclusive clinical evidence that trypanosome vaccine is useful in the treatment of cancer.

STREPTOCOCCUS CARRIERS

To the Editor:—A man aged 40 had a severe pharyngitis for about a year and since then has shown repeated positive throat smears for streptococci. He has been treated with sulfonamide drugs, penicillin, local applications of silver nitrate and gargles. He has little pain or soreness in the throat and has no tonsils or swelling in the pharynx. I told him that he must be considered a carrier and is potentially dangerous to other persons. He is not sick and seldom has a temperature above 100 F. What treatment is advised?

Thomas H. Meikle, M.D., Troy, Pa.

ANSWER:—Carriers of beta hemolytic streptococci should be examined for all possible foci which might account for persistence of the infection. Tonsils, lymphoid hyperplasia in the pharynx, nose and paranasal sinuses may be suspected. Nose cultures help to differentiate the nasal carriers. Examination of the nose including roentgenologic study of the sinuses is advisable.

Hamburger and Lemon (THE JOURNAL, March 30, 1946, p. 836) report good results in the treatment of streptococcus carriers with calcium penicillin in beeswax and peanut oil, 300,000 units daily for five to seven days. They state that this can be given intramuscularly to most ambulatory carriers in daily 1 cc. doses without interference with normal activities.

Determination of sensitivity of the organism to penicillin seems indicated in the case described, with regulation of the dose of penicillin according to the sensitivity. Injections of 40,000 to 50,000 units of penicillin every three or four-hours intramuscularly should attain more effective blood levels than a single daily dose, and should be continued for five to seven days.

Before undertaking further treatment diagnostic culture should be carried out to determine effectively that beta hemolytic streptococci are present as the cause of the condition.

OVULATION WITHOUT MENSTRUATION

To the Editor:—A normally developed woman aged 19 consulted me for the relief of nausea and vomiting of several weeks' duration. She has been married about one year and has never menstruated in her life. Several sisters have menstruated normally since age 12. Repeated examination revealed a normally progressing pregnancy of slightly more than three months' duration. Have other cases been observed in which pregnancy occurred in spite of primary amenorrhea? Can ovulation occur without subsequent menstruation? Must one assume that this patient had only one ovulation in her life and became pregnant at once?

F. C. Katzenstein, M.D., Salem, Ill.

ANSWER:—This young woman may have been late in developing and this may have been her first ovulation.

One must be sure that the woman is actually pregnant. Tumors must be considered, both uterine and extrauterine, some of which produce positive Friedman reactions, namely hydatidiform mole and chorionic carcinoma. Hematometra must not be overlooked.

Certain ovarian tumors must be considered which are defeminizing or masculinizing and therefore prevent menstruation.

Ovulation, as determined by indirect means such as temperature readings, apparently does occur without menstruation. Many women who menstruate occasionally over a period of months or years do become pregnant. Patients may ovulate but through some defect in the uterus, endometrium or hormone balance they may not menstruate.

In certain lower animals, particularly the rabbit, ovulation occurs with copulation.

BACKACHE AT NIGHT

To the Editor:—An apparently normal, well developed man aged 38 complains of backache which comes on only when he stays in bed. It has been present for the past fifteen years. The pain is in the lumbar area, is sufficient at times to disturb his sleep and disappears within one hour after he gets up. Hard and soft mattresses have been tried without relief. Roentgenograms of the spine reveal no pathologic condition. His posture is good, physical examination reveals essentially normal conditions and his habits are temperate. Please suggest possible causes of the pain.

M.D., New Jersey.

ANSWER:—Backache which is present only or primarily at night, and which disappears within a short time after arising, is almost always caused by a visceral lesion. A duodenal ulcer which is located on the posterior wall of the duodenum in close contact to the spine may be extremely difficult to visualize with barium roentgenograms. Such an ulcer may be the cause of backache such as that described. An excellent test for this, if the ulcer cannot be demonstrated in roentgenographic studies, would be a trial of ulcer management for about ten days. Such management should of course include some type of small feeding, including milk or cream at bedtime.

PAIN FOLLOWING INJURY TO THE TESTICLE

To the Editor:—A coach tells me that he has found a manipulation to relieve the excruciating pain and muscle spasm that follows an injury to the testicles, such as a kick. The manipulation consists of having the subject lie on his abdomen and giving firm, steady pressure on the middle of the back at about the level of the twelfth dorsal or first lumbar vertebra. He says that on several occasions he has used this with almost instant relief to the injured. Can you explain why a person gets instant relief from this manipulation?

M.D., Nebraska.

ANSWER.—No. However, it is true that from a neurologic angle one does occasionally see persons with a peculiar pain referred to various parts of the trunk and extremities that will follow injury to the back. The suggestion has been made at times that a particular nerve may be impinged on and that by pressure over the spine this may be relieved. However, if the testicular pain is caused by a blow to the testicle itself, it does not seem reasonable to think that any manipulation of the spine would have any effect on it.

USE OF HAPAMINE AND THE ANTIHISTAMINIC DRUGS

To the Editor:—Is there any contraindication to the simultaneous use of (1) "hapamine," the histamine-diazopropanate preparation (Parke Davis & Company) and (2) one of the antihistaminic drugs (diphenhydramine ["benadryl"] or tripeleminamine ["pyribenzamine"]) in a case of chronic atopic dermatitis? Would the antihistaminic drug neutralize the "hapamine" and prevent the supposed stimulation and production of the histamine antibodies (immune response) in the body?

William Sloan Lyles, M.D., New York.

ANSWER.—There is no contraindication for the simultaneous use of hapamine and any of the antihistaminic drugs. It is generally believed that the antihistaminic drugs exert their therapeutic effect by competing with histamine for various sites of action on the cell. There is no direct neutralizing effect of histamine. If antibodies are produced as a result of injections of "hapamine" (which is debatable) the use of antihistaminic drugs would not prevent the development of such antibodies.

PRECAUTIONS BEFORE GOING TO LATIN AMERICA

To the Editor:—What prophylactic injections for immunity should be taken prior to a short visit to Havana (three days) and the east coast of Guatemala (two days) by boat?

M.D., San Francisco.

ANSWER.—Before starting your trip you should have a successful vaccination against smallpox. If you already have a scar which is of more than five years' duration, then you should be revaccinated. You should also be immunized against typhoid-paratyphoid fever.

Visitors to the interior of any Latin American nation should consider vaccination against typhus and the possible use of protective medication against malaria.

DANGERS OF THERAPY WITH ESTROGENS

To the Editor:—A recent editorial on the estrogenic treatment of prostatic carcinoma stated that the use of estrogens for treatment of males was not without danger. What are dangers of estrogen therapy in prostatic hypertrophy and carcinoma?

Marks S. Shaine, M.D., New York.

ANSWER.—Anxiety concerning the prolonged administration of estrogen to human males largely stems from experimental studies. In certain strains of mice the estrogens readily evoke cancer of the breast or the interstitial cells of the testis. While treatment with estrogens in women has been implicated in cancer of the breast in only a few cases, any new therapeutic method with such a serious history in laboratory animals must be used with caution for some years.

SALICYLATES NOT USED TO PREVENT THROMBOSIS

To the Editor:—Enough experimental work has been done to demonstrate that if salicylic acid is given to laboratory animals it causes hypothermia and hypocoagulability. Similar action was found in the human subject. Since this action is much like that of "dicumarol," I am interested to learn whether or not any attempt was made to make therapeutic use of salicylates in conditions in which thrombosis is anticipated or is actually present?

Louis Newton, M.D., Bridgeport, Conn.

ANSWER.—As far as is known, no concerted attempt has been made to use salicylates therapeutically to prevent or treat thrombosis in man.

ALLERGY AND STRONTIUM SALICYLATE

To the Editor:—Are there any reported allergic reactions to strontium salicylate?

C. W. Atherton, M.D., Fairview, Ill.

ANSWER.—Allergic reaction to salicylates are not uncommon and consist chiefly of skin rashes associated with itching. The reports generally do not distinguish between strontium salicylate or other salicylates. It is quite certain, however, that those who are allergic to sodium salicylate would also be allergic to strontium salicylate. In this connection it is important to differentiate another type of salicylate allergy. In most instances of allergy to acetylsalicylic acid in which the symptoms are urticaria, asthma or rhinitis, sodium or strontium salicylate can be taken without ill effect.

ASTHMA

To the Editor:—Please discuss the indications for digitalis therapy in a prolonged attack of bronchial asthma.

M.D., West Virginia.

ANSWER.—Digitalis may be indicated in patients with asthma if there is any evidence of cardiac decompensation. This is not common in patients with asthma unless the condition has been severe and of many years' duration, or unless the patient has cardiac disease in addition to the asthma. The normal heart can tolerate many years of severe asthma without signs of decompensation. The usual signs of cardiac decompensation should guide the physician. Moist rales at the bases of the lungs, slight tenderness of the liver on palpation, enlargement of the liver, dependent edema and other signs of fluid retention indicate the usefulness of digitalis therapy.

"RADICAL CAUTERIZATION OF NOSTRILS"

To the Editor:—The reply in *The Journal* of Nov. 8, 1947, page 682, concerning radical cauterization of the nostrils in hay fever stated that "when allergic methods do not produce the desired results one may consider the advisability of employing conservative cauterizing methods, chiefly chemical." In those desperate cases in which there is almost continual sneezing, rhinorrhea and complete blocking of both nasal chambers, these chemicals are of little value and in some instances their application to an already inflamed mucous membrane will cause more irritation. These patients usually have large, pale blue inferior turbinates with redundant mucous membrane. The slightest irritation, whether by pollen, dust, fumes or chemicals, causes the redundant part to swell and block the nasal passages.

In such cases I have employed diathermy cauterization of the inferior turbinates for the past ten years. I use a bipolar turbine needle, which is inserted between the mucous membrane and the turbinate bone for a distance of about 1 inch (2.5 cm.) after the field has been anesthetized with a topical application of 5 per cent cocaine and a submucous infiltration of a 0.5 solution of procaine. The precise amount of tissue to be cauterized can be controlled by adjusting the gap between the parallel poles. In this way the electrocautery is confined to the submucosa. Contraction of the resulting scar pulls the mucous membrane down with it toward the turbinate bone and keeps it there permanently. A unipolar electrode, known as the Beck turbine needle, can also be used. With this needle it is not possible to control the exact amount of cauterization in the tissue surrounding the needle.

Treatments serve a twofold purpose, permanent shrinkage of the mucous membrane and substantial reduction or complete elimination of sneezing by destruction of the ends of afferent nerve fibers, thus raising the threshold for a given stimulus.

I have observed that if one half to two thirds of the anterior portion of the inferior turbinate is treated with electrocautery the sneezing subsides. Three to four treatments are required. If other nasal pathologic conditions exist, they should be corrected.

After treatment in some patients there develops a fever. Routinely I insert a nasal pack saturated in tyrothrycin and have the patient take penicillin by mouth as a prophylaxis. A nasal spray of 0.5 per cent solution of ephedrine is prescribed for home use. In severer cases, 0.5 per cent solution of cocaine is added.

Despite all precautions, the mucous membrane proper occasionally was burned by the electrocautery. In such cases regeneration took place and ill effects were not observed.

I do not agree that radical cauterization may produce such complications as sinusitis or asthma due to the loss of physiologic functions of the nasal tissues. I believe there is far greater danger of producing these conditions by allowing severe hay fever with complete nasal obstructions to continue, after having failed to relieve it through conventional methods. In a series of 150 cases none was made worse, and only in 4 cases was it necessary to resort to other methods, namely roentgen and radium therapy. This was used to control rhinorrhea, as the sneezing had already been reduced and good shrinkage had been obtained with the cautery.

The belief that the use of electrocautery will result in loss of physiologic function of the nasal tissue is founded on an academic premise rather than on practical experience. Certainly no ill effects on the inferior turbinate smell could be produced by the radical cauterization of the inferior turbinate.

Irving E. Kaufman, M.D., Chicago.
